Abstract

Background

Cardiomyocyte autophagy is essential for maintaining cardiac function. Our previous studies have found that β₁-adrenergic receptor autoantibody (β₁-AA) induced the decreased myocardial autophagic flux, which resulted in cardiomyocytes death and cardiac dysfunction. And other studies demonstrated that β₁-AA induced the decrease of AMPK phosphorylation, the key hub of autophagy pathway, while adiponectin up-regulated autophagic flux mediated by AMPK. However, it is not clear whether adiponectin improves the inhibition of myocardial autophagic flux induced by β₁-AA by up-regulating the level of AMPK phosphorylation.

Method

APN-KO and WT mice were subcutaneously injected with the peptide of the second extracellular loop of β₁-adrenergic receptor (β₁-AR-ECII) as antigen to establish β₁-AA active immunization model. The OD value of β₁-AA in serum of mice was detected by SA-ELISA to ensure the successful construction of active immunization model. The changes of cardiac function and myocardial fibrosis were detected by small animal ultrasound and Masson trichrome staining. The cardiomyocytes viability was assessed using a Cell Counting Kit-8. The mRNA levels of LC3B and Beclin1 in cardiomyocytes were measured by Real-time PCR. The protein levels of LC3 II, p62, AMP dependent protein kinase (AMP) - activated protein kinase (AMPK) and phosphorylated AMP dependent protein kinase (p-AMPK) in cardiomyocytes were detected by Western blotting.

Results

In this study, it has been confirmed that β₁-AA induced the decrease of AMPK phosphorylation level in both vivo and vitro. Moreover, pretreatment of cardiomyocytes with AMPK inhibitor Compound C could further reduce the autophagic flux induced by β₁-AA. Adiponectin deficiency could aggravate the decrease of myocardial AMPK phosphorylation level, autophagic flux and cardiac function induced by β₁-AA. Further, exogenous adiponectin could reverse the decline of AMPK phosphorylation level and autophagic flux induced by β₁-AA, and even reduce cardiomyocytes death. While pre-treated with the Compound C, the adiponectin treatment did not improve the decreased autophagosome formation, but still improved the decreased autophagosome clearance induced by β₁-AA in cardiomyocytes, suggesting that adiponectin up-regulated β₁-AA-induced decreased autophagic flux of cardiomyocytes partly depended on the AMPK.

Conclusion

This study is the first time to confirm that β₁-AA could inhibit myocardial autophagic flux by down regulating AMPK phosphorylation level. Adiponectin could improve the inhibition of myocardial
autophagic flux induced by β₁-AA partly dependent on AMPK, so as to provide an experimental basis for the treatment of patients with β₁-AA-positive cardiac dysfunction.

Background

With the development of the society, the morbidity of cardiac dysfunction are rising year by year, which has become a serious public health concern[1]. Immune disorder is one of the important causes of cardiac dysfunction[2]. In 1987, the researcher first discovered β₁-adrenergic receptor antibody (β₁-AA) as a product of immune disorder in serum of patients with dilated cardiomyopathy[3]. Subsequently, other researchers found that about 40% - 60% of patients with cardiac dysfunction were detected with β₁-AA in serum[4]. It can bind with β₁-adrenoceptor (β₁-AR) on the surface of cardiomyocytes membrane to cause persistent injury of cardiomyocytes, induce cardiomyocyte death and eventually lead to cardiac dysfunction[4]. Our team originally found that β₁-AA could induce the decrease of myocardial autophagic flux, which contributed to cardiac dysfunction[5]. Autophagy is a conserved intracellular degradation system, which maintains myocardial function and improves cardiac dysfunction by clearing intracellular degenerative and aging proteins or organelles[6, 7]. However, it is not clear how β₁-AA induces the decreased myocardial autophagic flux.

AMP dependent protein kinase (AMP) - activated protein kinase (AMPK) is an important signal molecule in the upstream of autophagy[8], which plays a positive role in regulating autophagic flux[9]. AMPK phosphorylation activated autophagy via Unc-51 like autophagy activating kinase 1 (Ulk1)-Beclin1 signaling pathway and through inhibiting mammalian target of rapamycin (mTOR) activity[10]. In primary neonatal rat cardiomyocytes, β₁-AA induced a decrease in AMPK phosphorylation[11]. However, whether the decrease of AMPK phosphorylation level is involved in the decline of myocardial autophagic flux induced by β₁-AA, and whether the increase of AMPK phosphorylation level could improve the decreased myocardial autophagic flux induced by β₁-AA remains to be explored.

The study has reported that adiponectin could phosphorylate AMPK by binding with adiponectin receptor on the surface of breast cancer cells, and then up-regulate autophagic flux[12]. Moreover, adiponectin has a wide range of myocardial protective effects, such as reducing myocardial infarction area, improving atherosclerosis, and resisting myocarditis[13, 14]. Studies have confirmed that adiponectin knockout (APN-KO) mice have cardiac dysfunction[15]. Therefore, we speculate that adiponectin may promote myocardial autophagic flux by up-regulating the decrease of AMPK phosphorylation level induced by β₁-AA, thus improving cardiac dysfunction.

This study has confirmed for the first time that the decrease of AMPK phosphorylation contributed to β₁-AA-induced decrease of myocardial autophagic flux both in vivo and vitro. Then, APN-KO mice were used to confirm the role of adiponectin deficiency in β₁-AA-induced decline of autophagic flux, cardiac dysfunction and myocardial fibrosis. Pretreatment of adiponectin verified that adiponectin could improve
β₁-AA-induced decrease of cardiomyocytes autophagic flux and cardiomyocytes death in vitro. Furthermore, Compound C was used to inhibit the AMPK to clarify the specific mechanism of adiponectin regulating autophagic flux. Our observations may open new insights into the treatment of β₁-AA positive cardiac dysfunction patients.

Method

1. Experimental animals

6-8-week-old male APN-KO mice (weight 18-20 g) were obtained from professor Bian Yunfei, Second Hospital of Shanxi Medical University. 6-8-week-old male C57BL/6 mice (weight 18-20g) were obtained from Animal Center of Shanxi Medical University. The mice with free diet were placed in a suitable temperature and humidity environment throughout the experiment. All procedures related to animals in this study were approved by the Ethics Committee of Shanxi Medical University, and followed the People’s Republic of China’s Guidelines for the Care and Use of Laboratory Animals.

2. Agarose gel electrophoresis

The genotypes of APN-KO mice were identified by agarose gel electrophoresis. The mouse tail tissue about 5 × 10⁻³ m was put into the EP tube, then the tail lysate was added, and put into the 55 °C constant temperature water bath for the night. The DNA of mice tail tissue was extracted and amplified, and the primer sequences were as follows: P1: GGCTCTCTGGGAGAGGCGAG, P2: CCATCACGGCCTGGTGTGCC, P3: TTCGCCATTCAGGCTGCGCA. The samples were agarose gel electrophoresis, after electrophoresis, the glue was placed in the automatic exposure instrument.

3. Establishment of β₁-AA actively immunized model

6-8-week-old male APN-KO mice and WT (C57BL/6) mice were randomly divided into actively immunized group and solvent control group, with 8 mice in each group. The peptide of β₁-AR-ECII (GLS, Shanghai, Chinese) was dissolved and diluted with Na₂CO₃ solution (100 mM, pH 11.0), and then mixed with Freund's complete adjuvan (Sigma-Aldrich, USA). After 1:1 emulsification and mixing, the mice were immunized with multiple injected subcutaneously into the back (0.4 μg/g) during the first immunization. Subsequently, diluted peptide of β₁-AR-ECII emulsified with incomplete Freund's adjuvant (Sigma-Aldrich, USA), and single subcutaneous injection was used to strengthen immunization once every 2 weeks for 12 weeks. In the solvent control group, the same amount of Na₂CO₃ solution was used to replace the antigen solution (Supplementary Figure).

4. SA-ELISA

SA-ELISA was used to detect the level of β₁-AA in the serum of actively immunized mice described previously[6]. The 96 well plates was used for antigen coating, and blank control group, solvent control group, positive control and actively immunized group were set up. β₁-AR-ECII was dissolved in Na₂CO₃
(100 mM pH=11.0) to prepare a solution with the final concentration of 10 μg/ml, and 50 μl was added into each well. Except for the blank control group, the other groups were coated with antigen at 4 °C overnight. The wells were saturated with PMT (1% (w/v) bovine serum albumin, 0.1% (v/v) Tween 20 in PBS, PH 7.4). The solvent control group, positive control, blank control and serum to be tested were diluted and added to 96 well plates. Then, the 96 well plates was added with biotinylated antibody (Zhongshan Golden Bridge Biotechnology, 1:2000) and horseradish peroxidase streptavidin (Zhongshan Golden Bridge Biotechnology, 1:2000) in 96 well plates. The above steps were respectively incubated at 37 °C for 1 h. The substrate (2.5 mM H₂O₂, 2 mM 2, 2'-azinodi (ethylbenzthiazoline) sulfuric salt (ABTS, Bio Basic Inc., AD0002, Markham, ON, Canada)) was added for 30 min. Finally, the 96 well plates was put into the microplate reader, and the OD value of each group was measured at 405 nm.

5. Affinity chromatography

First, a β₁-AA-positive animal model was established by actively immunized rats with β₁-AR-ECII, as described in the previous studies[16]. Then, animal serum from actively immunized rats and the control group were collected and extracted using MAbTrap Kit (GE Healthcare, Uppsala, Sweden) for affinity and purification of IgG.

6. Cell culture

H9c2 cells were purchased from Chinese Academy of Sciences Cell Bank (Shanghai, China). H9c2 cells were cultured in a complete medium containing 10% fetal bovine serum (Sijiqing, Shanghai, China) and 100 U/ml penicillin and 100 μg/ml streptomycin (Solarbio, P1400-100, Beijing, China), and were incubated at 37 °C in a humidified atmosphere of 5% CO₂. The cells were subcultured every other day. Cell grouping and treatment: control group (treated with 1 μM negative IgG for 24 h), β₁-AA group (treated with 1 μM β₁-AA for 24 h), β₁-AA + adiponectin group (450-27, pepro tech, USA) (pretreated with 10 μg/l adiponectin for 1 h and then treated with 1 μM β₁-AA for 24 h), β₁-AA + adiponectin + Compound C (s7840, Selleck, USA) (pretreated with 20 μM Compound C for 30 min, then 10 μg/l adiponectin was added for 1 h before adding 1 μM β₁-AA for 24 h), β₁-AA + Compound C group (pretreated with 20 μM Compound C for 30 min and then added 1 μM β₁-AA for 24 h).

7. Western Blotting

Western blotting was used to detect the protein expression levels of LC3B (ab48394, Abcam, 1:1000), p62 (ab56416, Abcam, 1:1000), AMPK (#5831, CST, 1:1000), p-AMPK (#2535, CST, 1:1000) in each group. Samples of each group were collected and added with RIPA lysis buffer (p0013b, beyond biotechnology, China) for protein extraction. BCA Kit (23225, Thermo Scientific, Rockford, IL, USA) was used to determine the protein concentration, and then boiled to denature. The protein was analyzed by SDS-PAGE assay (the sample volume was 40 μg) and transfered to the PVDF membrane (IPVH00010, Millipore, Billerica, MA, USA). Then blocking for 2 h in 5% non-fat dry milk which was dissolved with 1 × Tris-buffered saline and incubated with the corresponding antibodies at 4 °C overnight. TBST was used to wash the
membranes, then the membranes were incubated with the corresponding secondary antibodies (zb-2305, zb-2301, Zhongshan Golden Bridge biotechnology, 1:1000) at room temperature. After washing the membrane with TBST, the membranes were placed in the automatic exposure instrument. After adding Super ECL Plus (Applygen Technologies), the blots were exposed and the gray value was analyzed by Image J. GAPDH was used as internal references to calculate the relative expression of different proteins.

8. Real-time PCR

We detected the mRNA levels of autophagy related genes Beclin1 and LC3B by Real-time PCR. Firstly, total RNA was extracted by Trizol method, then the total RNA was reverse transcribed to cDNA. We used SYBR Green Kit (Takara, Japan) to amplify. The specific sequence of primers were as follows: Beclin1 (Gen-Bank ID NM_001034117.1), upstream primer: 5′-GAAACTGGACAGGCTTTCAAGA-3′, downstream primer: 5′-ACCATCTGGCAGGTTTCAATA-3′. LC3B (Gen-Bank ID NM_022867.2), upstream primer: 5′-AGCTCTGAAGCAGCGCAACAGCAACA-3′, downstream primer: 5′-GCTCCATGCAGGTAGCAGGAA -3′. GAPDH (Gen-Bank ID NM_017008.3), upstream primer: 5′-GGCACAGTCAAGGCTGAGAATG-3′, downstream primer: 5′-ATGGTGTTGAAGACGCCAGTA -3’. GAPDH was selected as the internal control. Data was quantified by the relative quantitative \(2^{-\Delta\Delta Ct} \) method.

9. CCK-8

Cell viability was measured with a cell counting kit-8(CCK-8). The H9c2 cells were seeded on 96 well plates (2 × 10^9/l). After H9c2 cells adhered to the wall, the H9c2 cells were pretreated with 5 μg/l, 10 μg/l and 30 μg/l adiponectin for 1 h before adding 1 μM \(\beta_1\)-AA for 24 h. Then, 10 μl CCK-8 reagent (CK04, Dojindo Molecular Technologies, Kumamoto, Japan) was added into each well. When the color of the solution changes to brown yellow, the absorbance values of each group at 450 nm were detected by microplate reader. According to the absorbance value of each group, the cell survival rate of each experimental group compared with the control group was calculated. viability % = [(AS−AB)/(AC−AB)]×100%, where AS is the absorbance of the samples with \(\beta_1\)-AA, AC is the absorbance of the DMEM media, and AB is the absorbance of the control.

10. Small animal ultrasound

The changes of cardiac function in mice were detected by small animal ultrasound. A small animal anesthesia machine was used for gaseous anesthesia, then put the mice into the anesthesia box and wait for the mice to faint. Fix the anesthetized mice on the mouse plate with adhesive tape, and maintain anesthesia by inhalation, remove the hair in the precordial area of the mice with depilatory creams, and gently wipe the residual hair with three distilled water to avoid causing artifacts. Fix the mice on the ultrasound platform, and smear the coupling agent on the precordial area of the mice. The left ventricular ejection fraction (EF%), Fractional shortening (FS%), LV internal diameter at end systole (LVID (s)) and LV internal diameter at end diastole (LVID (d)) were measured by M-mode ultrasound in the short axis section of the heart. After the detection, the precordial coupling agent was wiped off and put back into the cage.
11. Masson trichrome staining

Masson trichrome staining was used to observe the degree of myocardial fibrosis in mice. At the 12 week of immunization, mice were killed. The remaining blood in the heart was pumped out in PBS and fixed in 4% paraformaldehyde. The fixed tissue was washed with water and embedded in paraffin and sectioned (4 μm). After dewaxing, the tissue was stained with masson trichrome stain kit (Solarbio, Beijing, China) and sealed with neutral gum. All tissue slides were analyzed by optical microscopy (Olympus, BX45, Olympus Corporation, Tokyo, Japan) by the double-blind fashion.

12. Statistical analysis

Data are expressed as means ± SD. Statistical analysis was performed with SPSS software (version 16.0, SPSS Inc., Chicago, IL, USA). Two independent sample tests were used to compare the means of two independent samples and one-way ANOVA was applied after a Bonferroni post hoc test for more than two samples. \( P < 0.05 \) were considered statistically significant.

Results

1. \( \beta_1 \)-AA inhibited autophagic flux in myocardial tissues by reducing AMPK phosphorylation

Firstly, the effect of \( \beta_1 \)-AA on myocardial AMPK phosphorylation was investigated. The results showed that after active immunization with \( \beta_1 \)-AR-ECII for 8 weeks, the AMPK phosphorylation level (p-AMPK/AMPK) of myocardial tissues was considerably decreased (fig. 1a). We also found that the AMPK phosphorylation level (p-AMPK/AMPK) of H9c2 cells was also significantly decreased after stimulation of \( \beta_1 \)-AA for 24 hours (fig. 1b). The above results suggested that \( \beta_1 \)-AA could induce the decrease of AMPK phosphorylation in myocardial tissues.

In order to clarify the role of decreased AMPK phosphorylation in the decline of autophagic flux induced by \( \beta_1 \)-AA, H9c2 cells were pretreated with Compound C, an AMPK inhibitor, and then treated with \( \beta_1 \)-AA for 24 hours. The results showed that the inhibition of AMPK by Compound C further aggravated the decline of Beclin1 and LC3B mRNA levels (fig. 1c) and LC3 II protein levels induced by \( \beta_1 \)-AA (fig. 1d), and aggravated the accumulation of p62 protein (fig. 1d). These results suggested that \( \beta_1 \)-AA could inhibit autophagic flux of cardiomyocytes by reducing AMPK phosphorylation.

2. Adiponectin deficiency aggravated the decrease of AMPK phosphorylation induced by \( \beta_1 \)-AA in myocardial tissues.

To investigate the effect of adiponectin on \( \beta_1 \)-AA-induced decrease of myocardial AMPK phosphorylation, APN-KO mice was used to confirm the role of adiponectin deficiency on \( \beta_1 \)-AA-induced decrease of myocardial AMPK phosphorylation from reverse. First of all, the genotypes of APN-KO mice were identified by agarose gel electrophoresis to ensure the success of adiponectin gene knockout (fig. 2a). After that, APN-KO mice and WT mice were immunized with \( \beta_1 \)-AR-ECII for 8 weeks. Western blotting was
used to detect the phosphorylation of AMPK in the myocardial tissues. The results showed that compared with the control group, the myocardial AMPK phosphorylation level of WT immunized mice was decreased (fig. 2b), and the myocardial AMPK phosphorylation level of APN-KO immunized mice was further decreased (fig. 2b), which suggested that adiponectin deficiency aggravated the decrease of AMPK phosphorylation induced by β₁-AA.

3. Adiponectin deficiency aggravated the decline of autophagic flux induced by β₁-AA in myocardial tissues.

In order to clarify the role of adiponectin in the decrease of myocardial autophagic flux induced by β₁-AA, Real-time PCR and Western blotting were used to detect the changes of autophagy related genes and proteins in the myocardial tissues of APN-KO mice and WT mice after active immunization for 2 weeks. The results showed that the mRNA levels of Beclin1 and LC3B (Fig. 3a) and protein levels of LC3 II in APN-KO actively immunized mice were significantly decreased (Fig. 3c) and the protein levels of p62 were significantly increased (Fig. 3c) compared with WT group, but there were no significant differences in autophagy related genes and proteins between WT actively immunized mice and WT group (Fig. 3a, c). The results suggested that the myocardial autophagic flux of APN-KO mice decreased before that of WT mice after active immunization for 2 weeks.

Then we continued to immunize APN-KO mice and WT mice for 4 weeks. The autophagic flux of APN-KO actively immunized mice was further decreased than that of WT actively immunized mice at 4 weeks(Fig. 3b, d). The above results suggested that compared with WT actively immunized mice, APN-KO actively immunized mice presented a decrease in myocardial autophagic flux earlier, and with the prolongation of immunization time, APN-KO actively immunized mice showed a further decrease in myocardial autophagic flux.

4. Adiponectin deficiency aggravated cardiac dysfunction induced by β₁-AA

To investigate the role of adiponectin in the cardiac dysfunction induced by β₁-AA, small animal ultrasound was used to detect the changes of cardiac function in WT mice and APN-KO mice after active immunization for 8 weeks. The results indicated that compared with the WT group, the left ventricular ejection fraction (EF%) and Fractional shortening (FS%) were significantly decreased, LV internal diameter at end systole (LVID (s)) and LV internal diameter at end diastole (LVID (d)) were significantly increased in APN-KO actively immunized mice (Fig. 4a, b), but there was no significant difference between WT actively immunized mice and the WT group (Fig. 4a, b). It is suggested that APN-KO actively immunized mice developed cardiac dysfunction prior to WT actively immunized mice at 8 weeks.

Then we continued to immunize APN-KO mice and WT mice for 12 weeks. The results indicated that compared with WT actively immunized mice, EF% and FS% of APN-KO actively immunized mice were further decreased, LVID (s) and LVID (d) were further increased in APN-KO actively immunized at the 12 weeks after active immunization(Fig. 4c, d). Therefore, the heart function of APN-KO mice was further
deteriorated with the prolongation of immunization time. These results suggested that the cardiac dysfunction of APN-KO actively immunized mice was earlier than that of WT actively immunized mice, and the cardiac function of APN-KO actively immunized mice deteriorated with the prolongation of immunization time.

After 12 weeks of active immunization, the myocardial tissue of mice in each group was taken and the degree of myocardial fibrosis was detected by Masson trichrome staining. The results showed that the degree of myocardial fibrosis (blue stained area) in APN-KO actively immunized mice was more severe than that of WT actively immunized mice (Fig. 4e).

5. Adiponectin improved $\beta_1$-AA-induced H9c2 cell death

H9c2 cells were pretreated with different concentrations of adiponectin to explore whether adiponectin could improve the decline in the cell viability induced by $\beta_1$-AA. The results showed that compared with the control group, the cell viability of H9c2 cells was decreased significantly after $\beta_1$-AA stimulation, and 10 $\mu$g/l adiponectin could significantly reverse the decline of cell viability induced by $\beta_1$-AA. While 5 $\mu$g/l adiponectin could not restore the decreased cell viability. 30 $\mu$g/l adiponectin showed a trend of recovery, but there was no significant difference compared with $\beta_1$-AA group (Fig. 5a). The above results suggested that 10 $\mu$g/l adiponectin had a significant myocardial protective effect.

6. Adiponectin up-regulated the decreased autophagic flux in H9c2 cells after $\beta_1$-AA stimulation, which was partly dependent on AMPK

In order to verify whether adiponectin could up-regulate the decrease of autophagic flux induced by $\beta_1$-AA in H9c2 cells. We pretreated H9c2 cells with adiponectin to detect the changes of autophagic flux. Compared with $\beta_1$-AA group, adiponectin pretreatment could reverse the decrease of Beclin1 and LC3B mRNA levels (Fig. 5c), LC3 II protein levels (Fig. 5d) and p62 protein accumulation (Fig. 5e) after $\beta_1$-AA treatment, suggesting that adiponectin could improve the decline of autophagic flux induced by $\beta_1$-AA.

In order to verify whether adiponectin restored autophagy flux by up-regulating AMPK phosphorylation, H9c2 cells were pretreated with Compound C, an AMPK inhibitor. The results showed that adiponectin could not improve the decrease of AMPK phosphorylation induced by $\beta_1$-AA after compound C pretreatment ($\beta_1$-AA + APN + Compound C group) (Fig. 5b), suggesting that adiponectin could not up-regulate AMPK phosphorylation when AMPK was inhibited. Meanwhile, adiponectin could not reverse the decrease of Beclin1, LC3B mRNA (Fig. 5c) and LC3 II protein (Fig. 5d) induced by $\beta_1$-AA after Compound C pretreatment, that means adiponectin up-regulated the decrease of autophagosome formation dependent on AMPK. However, adiponectin could still improve the accumulation of p62 protein induced by $\beta_1$-AA after Compound C pretreatment (Fig. 5e), suggesting that adiponectin up-regulated the decrease of autophagosome clearance independent on AMPK. These results suggested that adiponectin up-regulated decreased autophagic flux in H9c2 cells after $\beta_1$-AA treatment, which was partly dependent on AMPK.
Discussion

We have provided the first evidence that \( \beta_1 \)-AA induced a decrease in myocardial autophagic flux by lowering AMPK phosphorylation. Meantime, we confirmed that adiponectin deficiency aggravated a decrease in myocardial autophagic flux induced by \( \beta_1 \)-AA. We further proved that adiponectin pre-treatment could reverse the decline of myocardial AMPK phosphorylation and autophagy flux after \( \beta_1 \)-AA treatment, which in turn improved H9c2 cell death. Subsequently, adopting AMPK inhibitor Compound C pre-treatment with H9c2 cells, we found that adiponectin up-regulated decreased autophagic flux induced by \( \beta_1 \)-AA, which partly depended on the AMPK.

Cardiac dysfunction has become one of the main cause of people's death, and lays a great burden on people's economy\(^1\). Immune disorders are one of the important causes of heart dysfunction\(^2\). Clinical studies have shown that \( \beta_1 \)-AA, products of immune disorders, exists in the serum of patients with dilation cardiomyopathy and a variety of cardiovascular diseases\(^18,19\). As an autoantibody against \( \beta_1 \)-adrenoceptor, \( \beta_1 \)-AA binds with \( \beta_1 \)-AR on the surface of cardiomyocytes, and plays an adrenergic receptor agonist like effect of positive chronotropic, positive inotropic and positive transformation conduction, which results in cardiomyocyte death and even cardiac dysfunction\(^20\). Our team has originally found that the decrease of myocardial autophagic flux induced by \( \beta_1 \)-AA is a pivotal cause of cardiomyocyte death and even cardiac dysfunction\(^5\). Autophagy, which is a mechanism of 'self-devouring', wraps aging, denaturation, excess proteins and organelles, then fusing with lysosomes, finally degrade to maintain cellular homeostasis\(^6\). Additionally, up-regulation of myocardial autophagic flux with autophagy agonists could improve \( \beta_1 \)-AA-induced cardiac dysfunction, suggesting that \( \beta_1 \)-AA-induced decline in myocardial autophagic flux is involved in the occurrence and development of cardiac dysfunction\(^5\). However, the mechanism by which \( \beta_1 \)-AA induces the decline of myocardial autophagic flux is yet unclear.

As an important upstream signal molecule of autophagy, AMPK could directly activate autophagy initiation complex Ulk1 and phosphorylate downstream Beclin1 to start autophagy, or inhibit mTOR activity to activate autophagy\(^10\). AMPK was originally defined as a protein kinase derived from rat liver. It exists as a trimeric complex consisting of catalytic \( \alpha \) subunits and regulatory \( \beta \) and \( \gamma \) subunits\(^21\). When the cellular energy status changes, the upstream kinase Liver kinase B1 (LKB1) phosphorylates the threonine residues (Thr-172) in the kinase domain to activate AMPK\(^22\). The study revealed that LPS induced a decrease in AMPK phosphorylation in acute lung injury, which resulted in autophagy inhibition. While the phosphorylation level of AMPK was restored, the decreased autophagy was also improved\(^23\). Therefore, the decrease of AMPK phosphorylation level may be an important reason for autophagy inhibition. This study and other studies have confirmed that \( \beta_1 \)-AA could induce a decrease in the phosphorylation of myocardial AMPK in vivo and in vitro\(^11\). We speculated that \( \beta_1 \)-AA induced a decline in myocardial autophagic flux due to inhibiting the phosphorylation of AMPK. In order to verify this speculation, we used AMPK inhibitor Compound C to pretreat H9c2 cardiomyocytes before adding \( \beta_1 \)-AA to detect changes in autophagic flux. It is worth noting that the autophagic flux is a dynamic process,
including the formation and maturation of autophagosomes, combining with lysosomes to form autophagolysosomes, and finally degrading the contents in an acidic environment to maintain the cell’s homeostasis\cite{24}. Beclin1, LC3 II, and p62 are commonly autophagy makers\cite{25}. Beclin1, LC3 II proteins are associated with the formation of autophagosomes\cite{26,27}. Reduction protein expression of p62, the substrate of autophagy, represents the clearance of autophagosomes\cite{28}. From the formation of autophagosomes to the clearance of autophagosomes, it is a complete autophagic flux\cite{24}. The results demonstrated that inhibition of AMPK could further aggravate the decrease of Beclin1 and LC3B mRNA and LC3 II protein level induced by β1-AA, and aggravate the accumulation of p62 protein, suggesting that β1-AA reduced myocardial autophagic flux by inhibiting AMPK phosphorylation. If we could effectively up-regulate the level of AMPK phosphorylation in cardiomyocytes, it is possible to improve the inhibition of autophagic flux induced by β1-AA.

Adiponectin could up-regulate AMPK phosphorylation and then up-regulate autophagy. The evidence demonstrates that adiponectin up-regulates the autophagic flux of skeletal muscle cells by phosphorylating AMPK\cite{29}, and also activates autophagy through the AMPK to reduce the apoptosis of HepG2 cells\cite{30}. Adiponectin is a adipokine that binds to adiponectin receptors and induces AMPK phosphorylation, followed by activated ULK1 kinase complex which is an important kinase complex for autophagy initiation, finally phosphorylates Beclin1 to initiate autophagy\cite{12,31}. Therefore adiponectin up-regulates autophagic flux through AMPK-ULK1. Other study demonstrated that adiponectin could induce AMPK phosphorylation in the mouse hypothalamus and in the hypothalamus of APN-KO mice, the level of AMPK phosphorylation is significantly decreased\cite{32}, suggesting that adiponectin deficiency induced the decrease in AMPK phosphorylation. In order to clarify the correlation between adiponectin and the decrease of AMPK phosphorylation level induced by β1-AA, we actively immunized APN-KO mice and WT mice with β1-AR-ECII to detect the changes of AMPK phosphorylation level in the myocardial tissue. The results showed that the phosphorylation level of myocardial AMPK in actively immunized APN-KO mouse was further reduced than that of actively immunized WT mice, suggesting that adiponectin deficiency aggravated the decrease in myocardial AMPK phosphorylation induced by β1-AA. Subsequently, we further explored the effect of adiponectin deficiency on myocardial autophagy induced by β1-AA.

Studies have shown that APN-KO mice existed a decreased myocardial autophagic flux, which included inhibition of autophagosome formation and clearance\cite{33}. And impaired autophagic flux resulted in insulin resistance in skeletal muscle of APN-KO mice\cite{34}. In order to confirm the role of adiponectin deficiency on myocardial autophagic flux induced by β1-AA, we determined the changes in myocardial autophagic flux in actively immunized APN-KO mice and WT mice. The results demonstrated that actively immunized APN-KO mice showed decreased myocardial autophagic flux before WT mice, and the myocardial autophagic flux of APN-KO mice was lower than that of WT mice at 4 weeks, suggesting that adiponectin deficiency significantly aggravated β1-AA-induced the decline in myocardial autophagic flux. Additionally, the decrease in myocardial autophagic flux could further cause obesity, metabolic disorders,
cardiac hypertrophy and myocardial contractile dysfunction\textsuperscript{[15]}. Therefore, we're going to prove that the effect of adiponectin deficiency on $\beta_1$-AA-induced cardiac dysfunction.

Animal experiments showed that APN-KO mice had severe cardiac dysfunction\textsuperscript{[33]}. Some studies found that three weeks after transverse aortic constriction (TAC), cardiac remodeling and myocardial systolic dysfunction were significantly greater in APN-KO mice than WT mice, indicating that adiponectin deficiency led to progressive cardiac remodeling and myocardial systolic dysfunction induced by hypertension\textsuperscript{[35]}. Moreover, adiponectin deficiency could promote angiotensin II induced myocardial fibrosis, and then led to cardiac dysfunction\textsuperscript{[36]}.

In this study, the changes of cardiac function in APN-KO mice and WT mice were detected by small animal ultrasound. The indexes included left ventricular ejection fraction (EF%), Fractional shortening (FS%), LV internal diameter at end systole (LVID (s)) and LV internal diameter at end diastole (LVID (d)). Among them, EF% is the measurement of how much blood is being pumped out of the left ventricle of the heart (the main pumping chamber) with each contraction, which is the central measure of left ventricular systolic function\textsuperscript{[37]}. FS% is used to estimate systolic function. LVID (s) and LVID (d) are used to assess the changes of cardiac function through the changes of ventricular volume, and the increase of these two indicators represent the decline of cardiac function. In brief, EF%, FS% and LVID (s) represent cardiac systolic function and LVID (d) represents diastolic function\textsuperscript{[38]}.

The results showed that at 8 weeks of active immunization, APN-KO mice developed cardiac dysfunction earlier than WT mice. And continued active immunization to 12 weeks, APN-KO mice had further decreased cardiac function compared with WT mice. It is suggested that adiponectin deficiency aggravated the cardiac dysfunction induced by $\beta_1$-AA. After that, the myocardial tissues of mice in each group were collected for 12 weeks. Then, Masson trichrome staining was used to detect the degree of myocardial fibrosis. The results found that the myocardial fibrosis of APN-KO immunized mice was more serious than that of WT immunized mice. These results indicated that adiponectin deficiency aggravated the decline of myocardial autophagic flux induced by $\beta_1$-AA, and then led to cardiac dysfunction and myocardial fibrosis. Therefore, whether adiponectin can be used as a potential therapeutic target to up-regulate myocardial autophagic flux and improve cardiac dysfunction, and whether AMPK is a possible regulatory mechanism still needs to be further verified.

Then we pretreated H9c2 cells with adiponectin before adding $\beta_1$-AA, the results showed that adiponectin indeed up-regulated the decreased AMPK phosphorylation and inversed the inhibited formation of autophagosomes and the accumulation of p62 protein. These results indicated that adiponectin could improve the decrease in myocardial autophagic flux induced by $\beta_1$-AA. In order to verify the role of AMPK phosphorylation in the up-regulation of myocardial autophagic flux by adiponectin, H9c2 cells were pretreated with Compound C as an AMPK inhibitor. And found that adiponectin did not improve the decreased mRNA expression of LC3B, Beclin1 and protein expression of LC3 II, indicating that adiponectin improved the inhibited formation of autophagosomes induced by $\beta_1$-AA dependent on AMPK. To our surprise, adiponectin improved the accumulation of p62 protein, which was unaffected by Compound C, suggesting that adiponectin promoted autophagosomes clearance independent on AMPK. Taken
together, adiponectin improved the decreased autophagic flux induced by β1-AA partly dependent on AMPK. Furthermore, we also found that adiponectin improved myocardial cell death induced by β1-AA, suggesting adiponectin played a protective role in the myocardial.

**Conclusion**

This study is the first to confirm that adiponectin could improve the decrease of myocardial autophagic flux induced by β1-AA, which is partly dependent on AMPK. Firstly, the decrease of AMPK phosphorylation is an important mechanism of the decrease of myocardial autophagic flux induced by β1-AA. Further, it was confirmed that adiponectin deficiency aggravated the decrease of β1-AA-induced myocardial autophagic flux and further aggravated cardiac dysfunction in vivo. Subsequently, we found that adiponectin pretreatment could indeed improve the decrease of cardiomyocytes autophagic flux induced by β1-AA, which was partly dependent on AMPK. The purpose of this study is to provide an experimental basis for the treatment of β1-AA positive patients with cardiac dysfunction from the perspective of improving myocardial autophagic flux.

**Abbreviations**

β1-AA: β1-adrenergic receptor autoantibody; β1-AR: β1-adrenoceptor; β1-AR-ECII: second extracellular loop of β1-adrenergic receptor; AMPK: AMP dependent protein kinase (AMP) - activated protein kinase; p-AMPK: phosphorylated AMP dependent protein kinase; APN-KO: adiponectin knockout; Ulk1: Unc-51 like autophagy activating kinase 1; mTOR: mammalian target of rapamycin; LKB1: kinase Liver kinase B1; EF%: left ventricular ejection fraction; FS%: Fractional shortening; LVID (s) LV internal diameter at end systole; LVID (d): and LV internal diameter at end diastole.

This work was aided by the National Natural Sciences Foundation of China (Grant No. 31871177), the Scientific and Technological Innovation Programs of Higher Education Institutions in Shanxi (No. 201802059), the Excellent Achievements (Science and Technology) Cultivation Project of Higher Education Institutions in Shanxi (No. 2020KJ034), the Scientific Research Project of Health Commission of Shanxi Province (No. 2018013), the Beijing Key Laboratory of Metabolic Disorder Related Cardiovascular Disease and the Shanxi “1331 Project” Key Subjects Construction.

**Authors’ contributions**

LW and CS conceived this study, generated hypotheses, and designed the experiments. CS, JL, YL, SG, WJ, and NN performed the experiments. YB provided the APN-KO mice. HH, XW, and HL analyzed the data. LW and CS wrote, reviewed, and edited the manuscript. LW supervised the project. All authors read and approved the final manuscript.

**Acknowledgements**

The authors thank Dr. Jimin Cao and Dr. Jin Wang for their generous help in the detection of cardiac function in mice.
