JIANG-SU ALGEBRA AS A FRAÎSSÉ LIMIT

SHUHEI MASUMOTO

Abstract. In this paper, we give a self-contained and quite elementary proof that the class of all dimension drop algebras together with their distinguished faithful traces forms a Fraïssé class with the Jiang-Su algebra as its limit. We also show that the UHF algebras can be realized as Fraïssé limits of classes of C*-algebras of matrix-valued continuous functions on [0, 1] with faithful traces.

1. Introduction

The Fraïssé theory was originally invented by Roland Fraïssé in [Fra54], where a bijective correspondence between countable ultra-homogeneous structures and classes with certain properties of finitely generated structures is established. The classes and corresponding ultra-homogeneous structures in question are called Fraïssé classes and Fraïssé limits of the classes respectively.

This theory has been, among the rest, a target of generalization to the setting of metric structures. For example, a general theory was developed in [Sch07], including connections with bounded continuous logic. In [Yaa15], Itaï Ben Yaacov concisely gave a self-contained presentation of a general theory, using a bright idea of approximate isomorphisms.

These attempts at generalization ended up successfully, and a number of metric structures are recognized as Fraïssé limits. Itaï Ben Yaacov [Yaa15] pointed out that the Urysohn universal space, the separable infinite dimensional Hilbert space, and the atomless standard probability space are examples of Fraïssé limits corresponding to suitable classes, and reconstructed discussion in [KS13] where the Gurarij space had been implicitly shown to be a Fraïssé limit of the class of all finite dimensional Banach spaces. The latter result was quantized by Martino Lupini [Lup14]: it was shown that the noncommutative Gurarij space is the Fraïssé limit of the class of all finite dimensional 1-exact operator spaces.

Among those instances are operator algebras. In [Eag+15], a more generalized version of Fraïssé theory for metric structures was presented, where the axioms of Fraïssé class were relaxed, and so the bijective correspondence established in the original theory no longer holds and the limit structures would have less homogeneity, though it is still powerful as a construction method. Using this version, the authors of the paper succeeded in realizing a family of AF algebras including the UHF algebras, the hyperfinite \( \text{II}_1 \) factor and the Jiang-Su algebra as (generalized) Fraïssé limits of a class of finite dimensional C*-algebras with distinguished traces.

2010 Mathematics Subject Classification. Primary 47L40; Secondary 03C98.

Key words and phrases. Fraïssé theory; Jiang-Su algebra; UHF algebra.
the class of finite dimensional factors and the class of dimension drop algebras with distinguished traces respectively.

The Jiang-Su algebra was first constructed by Jiang and Su in [JS99] as the unique simple monotracial C*-algebra among inductive limits of prime dimension drop algebras, which is KK-equivalent to the complex numbers C. One of the most important properties of this algebra is that it is strongly self-absorbing, because of which it plays a key role in the Elliott’s classification program of separable nuclear C*-algebras via K-theoretic invariants [ET08]. As is pointed out at the last section of [Eag+15], the proof that the Jiang-Su algebra satisfies this property is nontrivial, and there is a reasonable prospect that Fraïssé theoretic view of this algebra will give a shortcut. However, the proof given in [Eag+15] of the fact that the Jiang-Su algebra is a Fraïssé limit was still “a bit unsatisfactory” in the authors’ phrase, as it used the existence of the Jiang-Su algebra itself and relied heavily on Robert’s theorem (see [Eag+15, Remark 4.8 and Problem 7.2]).

In this paper, we prove that the collection of all the dimension drop algebras together with their distinguished faithful traces forms a Fraïssé class. The importance lies in that this proof is self-contained and quite elementary; in particular, it depends on neither the existence of the Jiang-Su algebra nor Robert’s theorem, so that it can be considered as a solution to [Eag+15] Problem 7.2. Also, we show that the UHF algebras are realized as a Fraïssé limit of a class of C*-algebras of matrix-valued continuous functions on the interval [0, 1] together with their distinguished faithful traces. Since this class differs from the one used in [Eag+15], this result implies a different homogeneity of the UHF algebras.

The paper consists of four sections. In the next section, we briefly introduce a version of Fraïssé theory for metric structures, which is essentially the same as the one in [Eag+15]. The third section contains the result on the UHF algebras. The argument included in this section is the basis of the fourth section, where the dimension drop algebras and the Jiang-Su algebra are dealt with.

2. Fraïssé Theory for Metric Structures

In this section, we present a general theory of Fraïssé limits in the context of metric structures, which is almost the same as the one in [Eag+15, Section 2]. The facts stated here are slight generalization of those of [Yaa15], and can be proved with trivial modification.

**Definition 2.1.** A language L consists of predicate symbols and function symbols. To each symbol in L is associated a natural number called its arity. We assume that L contains a binary predicate symbol d.

An L-structure is a complete metric space M together with an interpretation of symbols of L:

- to each n-ary predicate symbol P is assigned a continuous map \( P^M : M^n \rightarrow \mathbb{R} \), where the distinguished binary predicate symbol d corresponds to the distance function; and
- to each n-ary function symbol f is assigned a continuous map \( f^M : M^n \rightarrow M \).
An embedding of an \( L \)-structure \( M \) into another \( L \)-structure \( N \) is a map \( \varphi \) such that
\[
f^N(\varphi(a_1), \ldots, \varphi(a_n)) = \varphi(f^M(a_1), \ldots, a_n)
\]
and
\[
P^N(\varphi(a_1), \ldots, \varphi(a_n)) = P^M(a_1, \ldots, a_n)
\]
hold for any function symbol \( f \), any predicate symbol \( P \) and any elements \( a_1, \ldots, a_n \) in \( M \).

In this paper, we focus on unital C*-algebras with distinguished traces. We assume that \( L \) consists of the binary predicate symbol \( \d \), an unary predicate symbol \( \text{tr} \), binary function symbols \( + \) and \( \cdot \), an unary function symbols \( \lambda \) for each \( \lambda \in \mathbb{C} \) which should be interpreted as multiplication by \( \lambda \), an unary function symbol \( * \), and 0-ary function symbols 0 and 1. Then every unital C*-algebra with trace is understood as an \( L \)-structure in the canonical manner. Note that an embedding in the sense of Definition 2.1 is an injective trace-preserving \( * \)-homomorphism in this case, which we shall call a morphism in the sequel.

Remark 2.2. The definition of languages and metric structures varies by paper (see [Yaa15, Remark 2.2]), and the one we adopted here is the same as [Yaa15, Definition 2.1]. Some variants such as [Eag+15, Definition 2.1] require that all the maps which appear should be bounded or uniformly continuous, in which case the language carries additional informations. A C*-algebra is seemingly not an instance of a metric structure in these cases, because it is apparently unbounded and the multiplication is not uniformly continuous. Indeed, this can be easily overcome by using the unit ball as its representative, as in [Eag+15]. Anyway, the results of Fraïssé theory in both perspectives can be easily translated to each other, so we are in the same line as [Eag+15].

Definition 2.3. A class \( \mathcal{K} \) of \( L \)-structures is said to satisfy
- the joint embedding property (JEP) if for any \( A, B \in \mathcal{K} \) there exists \( C \in \mathcal{K} \) such that both \( A \) and \( B \) can be embedded in \( C \).
- the near amalgamation property (NAP) if for any \( A, B_1, B_2 \in \mathcal{K} \), any embeddings \( \varphi_1 : A \to B_1 \), \( \varphi_2 : A \to B_2 \), any finite subset \( G \subseteq A \) and any \( \varepsilon > 0 \), there exist embeddings \( \psi_i \) of \( B_i \) into some \( C \in \mathcal{K} \) such that \( d(\psi_1 \circ \varphi_1(a), \psi_2 \circ \varphi_2(a)) \) is less than \( \varepsilon \) for all \( a \in G \).

An \( L \)-structure \( A \) is said to be finitely generated if there exists a tuple \( \bar{a} = (a_1, \ldots, a_n) \in A^n \) such that the smallest substructure of \( A \) containing all \( a_1, \ldots, a_n \) is \( A \), for some \( n \in \mathbb{N} \). (Note that we assumed \( L \)-structures to be necessarily complete.) As we focus on unital C*-algebras with distinguished traces, this definition coincides with the usual one, that is, a (unital) C*-algebra (with its distinguished trace) is finitely generated if there exists a finite subset such that its closure by addition, multiplication, scalar multiplication and \( * \)-operation is dense in the whole C*-algebra.

Let \( \mathcal{K} \) be a class of finitely generated \( L \)-structures. For each \( n \in \mathbb{N} \), we denote by \( \mathcal{K}_n \) the class of all the pairs \( (A, \bar{a}) \), where \( A \) is a member of \( \mathcal{K} \) and \( \bar{a} \in A^n \) is
a generator of $A$. If $\mathcal{K}$ satisfies JEP and NAP, then we can define a pseudometric $d^{\mathcal{K}}$ on $\mathcal{K}_n$ by

$$d^{\mathcal{K}}((A, \vec{a}), (B, \vec{b})) := \inf \max_i d(f(a_i), g(b_i)),$$

where $\vec{a} = (a_1, \ldots, a_n), \vec{b} = (b_1, \ldots, b_n)$ and the infimum is taken over all the embeddings $f, g$ of $A, B$ into some $C$ in $\mathcal{K}$.

**Definition 2.4.** A class $\mathcal{K}$ of finitely generated $L$-structures with JEP and NAP is said to satisfy

- the **weak Polish property** (WPP) if $\mathcal{K}_n$ is separable with respect to the pseudometric $d^{\mathcal{K}}$ for all $n$.
- the **Cauchy Continuity Property** (CCP) if
  (1) for any $n$-ary predicate symbol $P$, the map $(A, (\vec{a}, \vec{b})) \mapsto P^A(\vec{a})$ from $\mathcal{K}_{n+m}$ into $\mathbb{R}$ sends Cauchy sequences to Cauchy sequences; and
  (2) for any $n$-ary function symbol $f$, the map $(A, (\vec{a}, \vec{b})) \mapsto (A, (\vec{a}, \vec{b}, f^A(\vec{a})))$ from $\mathcal{K}_{n+m}$ into $\mathcal{K}_{n+m+1}$ sends Cauchy sequences to Cauchy sequences.

**Remark 2.5.** CCP implies that $d^{\mathcal{K}}((A, \vec{a}), (B, \vec{b})) = 0$ holds if and only if there is an isomorphism between $A$ and $B$ sending $\vec{a}$ to $\vec{b}$ ([Yaa15] Remark 2.13 (i)). Note that if $\mathcal{K}$ is a class of finitely generated unital C*-algebras with traces and if it satisfies JEP and NAP, then it also satisfies CCP automatically, because all the relevant functions are 1-Lipschitz on the unit ball.

**Definition 2.6.** A class $\mathcal{K}$ of finitely generated $L$-structures is called a **Fraïssé class** if it satisfies JEP, NAP, WPP and CCP. A **Fraïssé limit** of a Fraïssé class $\mathcal{K}$ is a separable $L$-structure $M$ which is

1. a $\mathcal{K}$-structure: for any finite subset $F$ of $M$ and any $\varepsilon > 0$, there exists an embedding $\varphi$ of a member of $\mathcal{K}$ such that the $\varepsilon$-neighborhood of the image of $\varphi$ includes $F$.
2. $\mathcal{K}$-universal: every member of $\mathcal{K}$ can be embedded into $M$.
3. approximately $\mathcal{K}$-homogeneous: if $A$ is a member of $\mathcal{K}$ and $a_1, \ldots, a_n$ are elements of $A$, then for any embeddings $\varphi, \psi$ of $A$ into $M$ and any $\varepsilon > 0$, there exists an automorphism $\alpha$ of $M$ with $d(\alpha \circ \varphi(a_i), \psi(a_i)) < \varepsilon$ for $i = 1, \ldots, n$.

The definition here is more relaxed than that of [Yaa15] and close to [Eag+15].

**Definition 2.6.** our Fraïssé class is incomplete and lacks the hereditary property (see [Yaa15] Definitions 2.5 (ii) and 2.12)). Consequently, we cannot establish a bijective correspondence between Fraïssé classes and separable structures with homogeneity, which is a part of the main result of Fraïssé theory. The following theorem summarizes what remains in our framework.

**Theorem 2.7.** Every Fraïssé class $\mathcal{K}$ admits a unique limit. Moreover, for any $L$-structure $A_0$ in $\mathcal{K}$, there exists a sequence of embeddings $A_0 \xrightarrow{\varphi_0} A_1 \xrightarrow{\varphi_1} A_2 \xrightarrow{\varphi_2} \cdots$ such that $A_i$ belongs to $\mathcal{K}$ for all $i$ and its inductive limit coincides with the Fraïssé limit of $\mathcal{K}$.
A supernatural number is a formal product

\[ \nu = \prod_{\text{prime } p} p^{n_p}, \]

where \( n_p \) is either a non-negative integer or \( \infty \) for each \( p \) such that \( \sum_p n_p = \infty \).

In [Gli60, Theorem 1.12] it was proved that to each UHF algebra is associated a supernatural number as its complete invariant. Now, given a supernatural number \( \nu \), we denote by \( N(\nu) \) the set of all natural numbers which formally divides \( \nu \), and by \( K(\nu) \) the class of all the pairs \( (C[0, 1] \otimes \mathcal{M}_n, \tau) \), where \( n \in \mathbb{N}(\nu) \) and \( \tau \) is a faithful trace on the C*-algebra \( C[0, 1] \otimes \mathcal{M}_n \). Our goal in this section is to show that \( K(\nu) \) is a Fraïssé class the limit of which is the UHF algebra with \( \nu \) as its associated supernatural number.

First, note that \( C[0, 1] \otimes \mathcal{M}_n \) is canonically isomorphic to \( C([0, 1], \mathcal{M}_n) \), the C*-algebra of all the continuous \( \mathcal{M}_n \)-valued functions on the interval \([0, 1] \). In the sequel, we shall denote this C*-algebra by \( \mathcal{A}_n \) for simplicity. Next, let \( \tau \) be a probability Radon measure on \([0, 1] \), which is identified with a state on \( C[0, 1] \) by integration. Then \( \tau \otimes \text{tr} \) is clearly a trace on \( \mathcal{A}_n \), where \( \text{tr} \) is the unique normalized trace on \( \mathcal{M}_n \). It is easy to see that every trace on \( \mathcal{A}_n \) is of this form, so a probability Radon measure on \([0, 1] \) may also be identified with a trace on \( \mathcal{A}_n \). In the sequel, we simply write \( \tau \) instead of \( \tau \otimes \text{tr} \) and use adjectives for measures and traces in common. For example, a measure is said to be faithful if its corresponding trace is faithful. Also, all the measures are assumed to be probability Radon measures so that they always correspond to traces.

A measure is said to be diffuse or atomless if any measurable set of nonzero measure is parted into two measurable sets of nonzero measure. The following is often used in the sequel without referring.

**Lemma 3.1.** Let \( \sigma, \tau \) be faithful measures. If \( \sigma \) is diffuse, then there exists a unique non-decreasing continuous function \( \beta \) from \([0, 1] \) onto \([0, 1] \) with \( \beta_\sigma(\sigma) = \tau \). Moreover, \( \tau \) is diffuse if and only if \( \beta \) is a homeomorphism.

**Proof.** We first assume \( \sigma \) is equal to the Lebesgue measure \( \lambda \) and set \( \alpha(t) := \tau([0, t)) \). Note that \( \alpha \) is a strictly increasing upper semi-continuous function from \([0, 1] \) into \([0, 1] \). Let \( \beta \) be the unique non-decreasing function extending \( \alpha^{-1} \). Then

\[ \beta_\sigma(\lambda)([0, t)) = \lambda(\beta^{-1}([0, t))) = \lambda([0, \alpha(t))) = \alpha(t) = \tau([0, t)), \]

so \( \beta_\sigma(\lambda) \) is equal to \( \tau \). Also, if \( \tau \) is diffuse, then \( \alpha \) is continuous, whence \( \beta = \alpha^{-1} \) is a homeomorphism.

For the general case, let \( \beta_\sigma, \beta_\tau \) be such that \( (\beta_\sigma)_\lambda(\lambda) = \sigma \) and \( (\beta_\tau)_\lambda(\lambda) = \tau \). Then \( \beta := \beta_\tau \circ \beta_\sigma^{-1} \) satisfies \( \beta_\sigma(\sigma) = \tau \), which completes the proof. \( \square \)

The next propositions are immediate corollaries of the preceding lemma. Recall that a morphism between elements of \( \mathcal{K}(\nu) \) is an injective unital trace-preserving *-homomorphism.
**Proposition 3.2.** Let $\tau$ be a faithful trace on $\mathcal{A}_n$. Then for any faithful diffuse trace $\sigma$ on $\mathcal{A}_n$, there is a morphism $\varphi : \langle \mathcal{A}_n, \tau \rangle \rightarrow \langle \mathcal{A}_n, \sigma \rangle$.

**Proof.** Let $\beta$ be the non-decreasing continuous function as in Lemma 3.1. Then $\varphi := \beta^*$ is the desired morphism. $\square$

**Proposition 3.3.** The class $\mathcal{K}(\nu)$ satisfies JEP.

**Proof.** Suppose $n_1, n_2$ are in $\mathbb{N}(\nu)$ and put $n := \gcd(n_1, n_2)$. Then $n$ is also in $\mathbb{N}(\nu)$. Also, $\langle \mathcal{A}_n, \lambda \rangle$ is clearly embeddable into $\langle \mathcal{A}_n, \lambda \rangle$ by amplification. This fact together with Proposition 3.2 implies that $\mathcal{K}(\nu)$ satisfies JEP. $\square$

Next, we shall show that the class $\mathcal{K}(\nu)$ satisfies NAP. For this, we begin with proving that all the morphisms of $\mathcal{K}(\nu)$ are approximately diagonalizable.

**Definition 3.4.** A morphism $\varphi : \langle \mathcal{A}_n, \tau \rangle \rightarrow \langle \mathcal{A}_m, \sigma \rangle$ is said to be diagonalizable if for any there are a unitary $u \in \mathcal{A}_m$ and continuous maps $\xi_1, \ldots, \xi_k : [0, 1] \rightarrow [0, 1]$ such that

$$\varphi(f) = u \begin{pmatrix} f \circ \xi_1 & 0 \\ \vdots & \ddots \\ 0 & f \circ \xi_k \end{pmatrix} u^*$$

for all $f \in \mathcal{A}_n$.

In this paper, we shall call Eq. (1) a diagonal expression of $\varphi$, and $u$ and $\xi_1, \ldots, \xi_k$ its associated unitary and maps. Note that the union of the images of the maps associated to a diagonal expression is equal to $[0, 1]$, as morphisms are necessarily faithful. Also, compositions of diagonalizable morphisms are again diagonalizable.

**Proposition 3.5.** Let $\varphi : \langle \mathcal{A}_n, \tau \rangle \rightarrow \langle \mathcal{A}_m, \sigma \rangle$ be a morphism. Then for any finite subset $G \subseteq \mathcal{A}_n$ and any $\varepsilon > 0$, there exists a diagonalizable morphism $\psi : \langle \mathcal{A}_n, \tau \rangle \rightarrow \langle \mathcal{A}_m, \sigma \rangle$ with $\|\varphi(g) - \psi(g)\| < \varepsilon$ for all $g \in G$. Moreover, we can take $\psi$ so that the maps $\xi_1, \ldots, \xi_k$ associated to a diagonal expression of $\psi$ satisfies $\xi_1 \leq \cdots \leq \xi_k$.

**Proof.** For $t \in [0, 1]$, let $ev_t : \mathcal{A}_m \rightarrow \mathcal{M}_m$ be the evaluation $*$-homomorphism. Then $ev_t \circ \varphi$ is a unital $*$-homomorphism from $\mathcal{A}_n$ to the finite dimensional $\mathbb{C}^*$-algebra $\mathcal{M}_m$, so there exist a unitary $v_t \in \mathcal{M}_m$ and real numbers $s'_1, \ldots, s'_k \in [0, 1]$ such that the equation

$$ev_t \circ \varphi(f) = \text{Ad}(v_t)(\text{diag}(f(s'_1), \ldots, f(s'_k)))$$

holds for all $f \in \mathcal{A}_n$. Note that $\{s'_1, \ldots, s'_k\}$ coincides with the spectra of $ev_t \circ \varphi(\text{id}_{[0, 1]} \otimes 1_{\mathcal{M}_n})$ and $ev_t \circ \varphi(\text{id}_{[0, 1]} \otimes 1_{\mathcal{M}_n})$ with respect to the Hausdorff distance. Therefore, if we define

$$\xi_1(t) := \max\{s'_1, \ldots, s'_k\};$$

$$\xi_i(t) := \max\{s'_1, \ldots, s'_k\} \setminus \{\xi_1(t), \ldots, \xi_{i-1}(t)\},$$

then obviously $\xi_1, \ldots, \xi_k$ are continuous functions from $[0, 1]$ into $[0, 1]$ satisfying $\xi_1 \leq \cdots \leq \xi_k$. 

Next, fix $t_0 \in [0, 1]$. We claim that there exists $\delta(t_0) > 0$ with the following property: if $|t - t_0| < \delta(t_0)$, then there exists a unitary $w_{t_0} \in M_m$ with $\|v_t - w_{t_0}\| < \varepsilon$ such that the equation

$$ ev_{t_0} \circ \varphi(f) = \text{Ad}(w_{t_0})(\text{diag}(f(s_{t_0}^0), \ldots, f(s_n^0))) $$

holds for all $f \in \mathcal{A}_n$. To see this, let $s_1, \ldots, s_l$ be distinct eigenvalues of $ev_{t_0} \circ \varphi(\Id_{[0,1]} \otimes 1_{M_m})$ and take mutually orthogonal non-negative continuous functions $f_1, \ldots, f_l$ such that $f_i$ is constantly equal to 1 on some neighborhood of $s_i$ for each $i$. Note that if $e_{p,q}$ is a matrix unit of $M_m$, then $(ev_{t_0} \circ \varphi(f_i \otimes e_{p,q}))_{i,p,q}$ forms a matrix unit of $\text{Im}(ev_{t_0} \circ \varphi)$, and if $t$ is sufficiently close to $t_0$, then $(ev_t \circ \varphi(f_i \otimes e_{p,q}))_{i,p,q}$ is a matrix unit of a subalgebra of $\text{Im}(ev_t \circ \varphi)$ which is close to $(ev_{t_0} \circ \varphi(f_i \otimes e_{p,q}))_{i,p,q}$. Hence, as in the proof of [Dav96, Lemma III.3.2], we can find a unitary $w$ with $\|w - 1\| < \varepsilon$ such that

$$ w(ev_{t_0} \circ \varphi(f_i \otimes e_{p,q}))w^* = ev_t \circ \varphi(f_i \otimes e_{p,q}), $$

and $w_{t_0} := v_tw$ has the desired property.

Now take $\delta_0 > 0$ sufficiently small so that the inequalities

$$ \|g \circ \xi_i(s) - g\xi_i(t)\| < \varepsilon, \quad \|ev_g \circ \varphi(g) - ev_t \circ \varphi(g)\| < \varepsilon $$

hold for all $g \in G$ whenever $|s - t| < \varepsilon$, and consider an open covering

$$ \mathcal{U} := \{U_{\delta}(t) \mid t \in [0, 1] \& \delta < \min(\delta(t), \delta_0)\} $$

of $[0, 1]$, where $U_{\delta}(t)$ denotes the open ball of radius $\delta$ and center $t$. Since $[0, 1]$ is compact, there exists a finite subcovering, say $\{I_1, \ldots, I_l\}$. We denote the center of $I_j$ by $c_j$, and without loss of generality, we may assume $c_1 < \cdots < c_r$ and $I_j \cap I_{j+1} \neq \emptyset$ for all $j$. Take $\eta > 0$ and $b_j \in I_j \cap I_{j+1} \cap (c_j + \eta, c_{j+1} - \eta)$ for each $j$, and find a unitary $u \in \mathcal{A}_m$ such that

- $u(b_j)$ is equal to $v_{b_j}$ for all $j$;
- the image of $u$ on $[c_j + \eta, c_{j+1} - \eta]$ is included in the $\varepsilon$-ball of center $u(b_j)$; and
- the image of $u$ on $[c_j - \eta, c_j + \eta]$ is included in the path-connected subset

$$ \left\{ w \mid ev_{c_j} \circ \varphi(f) = \text{Ad}(w)(\text{diag}(f \circ \xi_1(c_j), \ldots, f \circ \xi_k(c_j))) \right\} $$

of unitaries,

which is possible by the claim we proved in the previous paragraph.

We shall set

$$ \psi(f) := \text{Ad}(u)(\text{diag}(f \circ \xi_1, \ldots, f \circ \xi_k)) $$

and show that this $\psi$ has the desired property. First, it is clear from the definition of $\xi_i$ that $\psi$ is trace-preserving. Now, suppose $t \in [c_j + \eta, c_{j+1} - \eta]$ and $g \in G$. Without loss of generality, we may assume that the norm of $g$ is less than 1. Then we have

$$ ev_t \circ \psi(g) = \text{Ad}(u(t))(\text{diag}(g \circ \xi_1(t), \ldots, g \circ \xi_k(t))) $$

$$ \sim_{3\varepsilon} \text{Ad}(u(b_j))(\text{diag}(g \circ \xi_1(b_j), \ldots, g \circ \xi_k(b_j))) = ev_{b_j} \circ \varphi(g) $$

$$ \sim_{\varepsilon} ev_t \circ \varphi(g). $$
On the other hand, if \( t \in [c_j - \eta, c_j + \eta] \), then
\[
ev_t \circ \psi(g) = \text{Ad}(u(t))(\text{diag}(g \circ \xi_1(t), \ldots, g \circ \xi_k(t)))
\]
\[
= e \text{Ad}(u(t))(\text{diag}(\xi_1(c_j), \ldots, g \circ \xi_k(c_j))) = \ev_{c_j} \circ \varphi(g)
\]
\[
\sim_e \ev_t \circ \varphi(g).
\]
Consequently, it follows that \( ||\varphi(g) - \psi(g)|| < 4\varepsilon \) for all \( g \in G \), which completes the proof. \( \square \)

The following proposition is also an immediate corollary of Lemma 3.1. However, as a preparation to the next section, we shall present a slightly ineffective proof.

**Proposition 3.6.** Let \( \tau, \sigma \) be faithful diffuse measures on \([0, 1]\). Then for any \( n \in \mathbb{N}(\nu) \) and any \( \varepsilon > 0 \), there exist \( m \in \mathbb{N}(\nu) \) and a diagonalizable morphism \( \varphi: \langle \mathcal{A}_n, \tau \rangle \rightarrow \langle \mathcal{A}_m, \sigma \rangle \) such that the images of the maps associated to a diagonal expression of \( \varphi \) have diameters less than \( \varepsilon \).

**Proof.** Since \( \tau \) is diffuse, there exists \( \delta > 0 \) such that \( \tau([t_1, t_2]) < \delta \) implies \( |t_2 - t_1| < 1/6 \). Take \( k \in \mathbb{N} \) so that \( m_1 := nk \) is in \( \mathbb{N}(\nu) \) and \( 1/k \) is smaller than \( \delta \). Then there are \( t_0 \in (1/2, 2/3) \) and \( r \in \mathbb{N} \) with \( \tau([0, t_0]) = r/k \). We set \( t_1 := \frac{k}{r}t_0 \) and \( t_2 := \frac{k}{r}t_0 \), so \( \tau = \frac{k}{r}t_1 + \frac{k}{r}t_2 \). By Lemma 3.1 one can find increasing maps \( \eta_1: [0, 1] \rightarrow [0, t_0] \) and \( \eta_2: [0, 1] \rightarrow [t_0, 1] \) such that \( \tau_i \) is equal to \( (\eta_i)_* (\sigma) \) for \( i = 1, 2 \). We set
\[
\xi_j := \begin{cases} 
\eta_1 & \text{if } j = 1, \ldots, r, \\
\eta_2 & \text{if } j = r + 1, \ldots, k,
\end{cases}
\]
and define \( \varphi_1: \mathcal{A}_n \rightarrow \mathcal{A}_{m_1} \) by
\[
\varphi_1(f) = \text{diag}(f \circ \xi_1, \ldots, f \circ \xi_k).
\]
Then it can be easily verified that \( \varphi_1 \) is a morphism from \( \langle \mathcal{A}_n, \tau \rangle \) to \( \langle \mathcal{A}_{m_1}, \sigma \rangle \), and that the images of the maps \( \xi_1, \ldots, \xi_k \) are either \([0, t_0]\) or \([t_0, 1]\), so their diameters are less than \( 2/3 \).

Now take \( d \in \mathbb{N} \) large enough so that \( (2/3)^d \) is less than \( \varepsilon \), and repeat the procedure above for \( d \) times to obtain a sequence
\[
\langle \mathcal{A}_n, \tau \rangle \xrightarrow{\varphi_1} \langle \mathcal{A}_{m_1}, \sigma \rangle \xrightarrow{\varphi_2} \cdots \xrightarrow{\varphi_{d-1}} \langle \mathcal{A}_{m_d}, \sigma \rangle.
\]
Then \( \varphi := \varphi_{d-1} \circ \cdots \circ \varphi_1 \) has the desired property. \( \square \)

**Proposition 3.7.** The class \( \mathcal{K}(\nu) \) satisfies NAP.

**Proof.** Let \( \varphi_1, \varphi_2 \) be morphisms from \( \langle \mathcal{A}_{m_0}, \tau_0 \rangle \) into \( \langle \mathcal{A}_{m'}, \sigma' \rangle \), \( \langle \mathcal{A}_{m''}, \sigma'' \rangle \) respectively, and \( G \) be a finite subset of \( \mathcal{A}_{m_0} \). Our goal is to show that given \( \varepsilon > 0 \), we can find morphisms \( \psi_1 \) and \( \psi_2 \) from \( \langle \mathcal{A}_{m'}, \sigma' \rangle \) and \( \langle \mathcal{A}_{m''}, \sigma'' \rangle \) respectively into some \( \langle \mathcal{A}_{m_2}, \tau_2 \rangle \in \mathcal{K}(\nu) \) with \( ||\psi_1 \circ \varphi_1(g) - \psi_2 \circ \varphi_2(g)|| < \varepsilon \) for all \( g \in G \). To see this, we may assume that \( m' = m'' = n_1 \) and \( \sigma' = \sigma'' = \tau_1 \), by Proposition 3.3 and that both \( \varphi_1 \) and \( \varphi_2 \) are diagonalizable, by Proposition 3.5.

Let \( \xi_1, \ldots, \xi_k \) be the maps associated to a diagonal expression of \( \varphi_i \). Take \( \delta > 0 \) so that \( |s - t| < \delta \) implies \( |g(s) - g(t)| < \varepsilon \) for any \( g \in G \), and apply Proposition 3.6 to
obtain a morphism \( \rho \) from \( \langle \mathcal{A}_n, \tau_1 \rangle \) into some \( \langle \mathcal{A}_m, \tau_2 \rangle \) such that the images of the maps associated to a diagonal expression of \( \rho \circ \varphi_i \) have diameters less than \( \delta/3 \) for each \( i \). Then applying Proposition 3.3 find a diagonalizable morphism \( \Phi_j \) such that the inequality \( \|\rho \circ \varphi_i(g) - \Phi_i(g)\| < \varepsilon \) holds for \( g \in G \), and that the maps \( \xi_j^1, \ldots, \xi_k^1 \) associated to a diagonal expression of \( \Phi_j \) satisfies \( \xi_j^1 \leq \cdots \leq \xi_k^1 \). Recalling the proof of Proposition 3.5, one can easily check that the diameters of the images of \( \xi_j^1 \) is still less than \( \delta/3 \).

We claim that the inequality \( \|\xi_j^1 - \xi_j^2\| < \delta \) holds for all \( j \). Suppose on the contrary that \( \xi_j^1(t) \geq \xi_j^2(t) + \delta \) at some point \( t \in [0, 1] \), and set \( c := \max \xi_j^2, d := \min \xi_j^1 \). Then applying Proposition 3.3 one can easily check that the diameters of the images of \( \xi_j^1 \) is still less than \( \delta/3 \).

Since \( d \) is larger than \( c \) by at least \( \delta/3 \), and since \( \Phi_j \) is trace-preserving, we have

\[
j = \sum_{l=1}^{j} \tau_2((\xi_l^2)^{-1}[0, c]) \leq n_2\tau_0([0, c]) < n_2\tau_0([0, d]) \leq \sum_{l=1}^{j} \tau_1((\xi_l^1)^{-1}[0, 1]) = j,
\]

which is a contradiction. Therefore, \( \|\xi_j^1 - \xi_j^2\| \) must be smaller than \( \delta \), as desired.

Now, let \( u_i \) be a unitary such that the equality

\[
\Phi_j(f) = \text{Ad}(u_i)(\text{diag}(f \circ \xi_1^1, \ldots, f \circ \xi_k^1))
\]

holds for all \( f \in \mathcal{A}_m \), and put \( \psi_1 := \rho \) and \( \psi_2 := \text{Ad}(u_1 u_2) \circ \rho \). Then for \( g \in G \), we have

\[
\psi_2 \circ \varphi_2(g) = \text{Ad}(u_1 u_2) \circ \varphi_2(g) \\
= \text{Ad}(u_1 u_2) \circ \varphi_2(g) \\
= \text{Ad}(u_1)(\text{diag}(g \circ \xi_1^1, \ldots, g \circ \xi_k^1)) \\
= \text{Ad}(u_1)(\text{diag}(g \circ \xi_1^1, \ldots, g \circ \xi_k^1)) \\
= \Phi_j(g) \\
= \varphi_j(g)
\]

which completes the proof. \( \square \)

**Theorem 3.8.** The class \( \mathcal{K}(\nu) \) is a Fraïssé class.

**Proof.** We have already shown that \( \mathcal{K}(\nu) \) satisfies JEP and NAP in Propositions 3.3 and 3.7. Also, it can be easily verified form the proof of Proposition 3.2 that \( \mathcal{K}(\nu) \) satisfies WPP. Since \( \mathcal{K}(\nu) \) automatically satisfies CCP, as is noted in Remark 2.5, it follows that \( \mathcal{K}(\nu) \) is a Fraïssé class. \( \square \)

We close this section by showing that the Fraïssé limit of \( \mathcal{K}(\nu) \) is the unique UHF algebra \( \mathcal{M}_\nu \) corresponding to the supernatural number \( \nu \). The following lemma will be needed for the proof.

**Lemma 3.9.** Let \( \langle \mathcal{A}_n, \tau \rangle \) be a member of \( \mathcal{K}(\nu) \). Then for any finite subset \( F \subseteq \mathcal{A}_n \) and any \( \varepsilon > 0 \), there exist a morphism from \( \langle \mathcal{A}_n, \tau \rangle \) into some \( \langle \mathcal{A}_m, \sigma \rangle \in \mathcal{K}(\nu) \) and
a finite dimensional $C^*$-subalgebra $\mathcal{B} \subseteq \mathcal{A}_m$ such that the image $\varphi[F]$ is included in the $\varepsilon$-neighborhood of $\mathcal{B}$.

Proof. We may assume $F = \{\text{id}_{[0,1]} \otimes 1_{B_a}\} \cup \{1_{C[0,1]} \otimes e_{i,j} | i, j = 1, \ldots, n\}$ where $\{e_{i,j}\}$ is the standard matrix unit of $\mathbb{M}_n$, because this set generates $\mathcal{A}_n$. Also, we may assume that $\tau$ is diffuse by Proposition 3.2. Now, let $\varphi$ be as in Proposition 3.6. Then

$$\varphi(\text{id}_{[0,1]} \otimes 1_{B_a}) = \text{diag}(\xi_1, \ldots, \xi_k)$$

$$\sim \varepsilon 1_{C[0,1]} \otimes \text{diag}(\xi_1(0), \ldots, \xi_k(0)),$$

so $\varphi[F]$ is included in the $\varepsilon$-neighborhood of the finite dimensional $C^*$-subalgebra $1_{C[0,1]} \otimes B_a$, as desired. \hfill $\square$

**Theorem 3.10.** The Fraïssé limit of $\mathcal{K} (\nu)$ is $\langle \mathbb{M}_\nu, \text{tr} \rangle$, where $\text{tr}$ is the unique trace on $\mathbb{M}_\nu$.

**Proof.** Let $\langle \mathcal{A}_n, \theta \rangle$ be the Fraïssé limit of $\mathcal{K}$. By $\mathcal{K}$-universality and Theorem 2.7, it is clear that $\mathcal{A}$ and $\mathbb{M}_\nu$ have the same K-theory. Therefore, it suffices to show that $\mathcal{A}$ is an AF algebra. For this, let $F$ be a subset of $\mathcal{A}$. Then given $\varepsilon > 0$, we can find a morphism $\varphi$ of some $\langle \mathcal{A}_n, \tau \rangle \in \mathcal{K} (\nu)$ into $\langle \mathcal{A}_n, \theta \rangle$ and a finite subset $F' \subseteq \mathcal{A}_n$ such that $F$ is included in the $\varepsilon$-neighborhood of $\varphi[F']$. On the other hand, by Lemma 3.9 there is a morphism $\psi$ from $\langle \mathcal{A}_n, \tau \rangle$ into some $\langle \mathcal{A}_m, \sigma \rangle \in \mathcal{K} (\nu)$ such that $\psi[F']$ is included in the $\varepsilon$-neighborhood of a finite dimensional $C^*$-subalgebra of $\mathcal{A}_m$. Since $\langle \mathcal{A}_n, \theta \rangle$ is $\mathcal{K}$-universal and approximately $\mathcal{K}$-homogeneous, there is a morphism $\psi: \langle \mathcal{A}_m, \sigma \rangle \rightarrow \langle \mathcal{A}_n, \theta \rangle$ such that $d(\psi(f), \psi(f'))$ is less than $\varepsilon$ for all $f, f' \in F'$. It follows that $F$ is included in the $3\varepsilon$-neighborhood of a finite dimensional $C^*$-subalgebra of $\mathcal{A}$, so by [Dav96, Theorem III.3.4], $\mathcal{A}$ is an AF algebra, which completes the proof. \hfill $\square$

3. The Jiang-Su Algebra

Let $p, q$ be natural numbers. We shall begin with the well-known observation that if $\{e_{i,j}\}_{i,j=1}^1$ and $\{f_{k,l}\}_{k,l=1}^1$ are the standard matrix units of $\mathbb{M}_p$ and $\mathbb{M}_q$ respectively, then $\{e_{i,j} \otimes f_{k,l}\}_{i,j,k,l=1}^1$ is a matrix unit of $\mathbb{M}_p \otimes \mathbb{M}_q$, so $\mathbb{M}_p \otimes \mathbb{M}_q$ is canonically identified with $\mathbb{M}_{pq}$. Now, the dimension drop algebra $\mathbb{Z}_{p,q}$ is defined by

$$\mathbb{Z}_{p,q} := \{ f \in \mathcal{A}_{pq} | f(0) \in \mathbb{M}_p \otimes 1_{\mathbb{M}_q} \quad \text{and} \quad f(1) \in 1_{\mathbb{M}_p} \otimes \mathbb{M}_q \},$$

where we took over the notation $\mathcal{A}_n = C([0,1], \mathbb{M}_n)$ from Section 5. It is said to be prime if $p$ and $q$ are co-prime. We denote by $\mathcal{K}$ the class of all pairs $(\mathbb{Z}_{p,q}, \tau)$, where $\mathbb{Z}_{p,q}$ is a prime dimension drop algebra and $\tau$ is a faithful trace on it.

In [JS99], Jiang and Su constructed the Jiang-Su algebra as an inductive limit of prime dimension drop algebras, and proved that it is the unique monotracial simple $C^*$-algebra among such inductive limits. Our goal here is to show that the Jiang-Su algebra together with its unique trace is the Fraïssé limit of the class $\mathcal{K}$. The direction of the proof is the same as that of Section 3, but we need some additional observations because of the pinching condition.
Notation 4.1. Let \( \xi = (\xi_1, \ldots, \xi_k) \) be a tuple of functions from \([0, 1]\) to \([0, 1]\). For \( s = 0, 1 \), we set \( F_s(\xi) = (\xi_1(s), \ldots, \xi_k(s)) \). Also, for \( t \in F_s(\xi) \), we denote by \( n'_t(\xi) \) the number of \( i \) with \( \xi_i(s) = t \). If the family \( \xi \) under consideration is apparent from context, then \( F_s(\xi) \) and \( n'_t(\xi) \) are simply written as \( F_s \) and \( n'_s \) respectively.

Lemma 4.2. Let \( \varphi : \mathbb{Z}_{p,q} \to \mathcal{A}_{p',q'} \) be a \(*\)-homomorphism of the form

\[
\varphi(f) = \text{diag}(f \circ \xi_1, \ldots, f \circ \xi_k),
\]

where \( \xi_1, \ldots, \xi_k \) are continuous functions from \([0, 1]\) into \([0, 1]\), and \( n'_s = n'_s(\xi) \) be as in Notation 4.1. Then the following are equivalent.

(i) There exists a unitary \( u \in \mathcal{A}_{p',q'} \) such that the image of \( \text{Ad}(u) \circ \varphi \) is included in \( \mathcal{A}_{p',q'} \).

(ii) The congruence equations

\[
\begin{align*}
qn_0^0 \equiv & \, pn'_0^1 \equiv 0 \pmod{q'}, \\
n'_0 \equiv & \, \mod{q'}, \\
n'_1 \equiv & \, \mod{p'} (t \neq 0, 1)
\end{align*}
\]

hold.

Moreover, if \( \mathbb{Z}_{p,q} \) is prime, then there exists a unitary \( v \in \mathcal{A}_{p',q'} \) with the following property: for any \( \psi : \mathbb{Z}_{p,q} \to \mathcal{A}_{p',q'} \) of the form

\[
\psi(f) = \text{diag}(f \circ \zeta_1, \ldots, f \circ \zeta_k),
\]

where \( \zeta_1 \leq \cdots \leq \zeta_k \) are continuous functions from \([0, 1]\) into \([0, 1]\), if the numbers \( n'_s(\zeta) \) satisfies Eq. 2, then the image of \( \text{Ad}(v) \circ \psi \) is included in \( \mathbb{Z}_{p,q} \).

Proof. First, we shall prove (i) \( \Rightarrow \) (ii). Let \( F_s = F_s(\xi) \) be as in Notation 4.1. For \( t \in F_0 \), take \( f' \in \mathbb{Z}_{p,q} \) such that \( f'(t) \) is a minimal projection in \( ev_t[Z_{p,q}] \) and \( f'(s) \) vanishes if \( s \in F_0 \). If \( t \neq 0, 1 \), then \( ev_0 \circ \varphi(f') \) is a projection of rank \( n'_0 \) in \( M_{p'} \otimes 1_{M_{q'}} \). Since the rank of any projection in \( M_{p'} \otimes 1_{M_{q'}} \) is necessarily a multiple of \( q' \), it follows that \( n'_0 \equiv 0 \pmod{q'} \). On the other hand, \( f^0(0) \) and \( f^1(1) \) are minimal projections in \( M_p \otimes 1_{M_q} \) and \( 1_{M_p} \otimes M_q \), so that their ranks are \( q \) and \( p \) respectively. Therefore, \( ev_0 \circ \varphi(f^0) \) and \( ev_0 \circ \varphi(f^1) \) are projections of ranks \( qn_0^0 \) and \( pn_1^1 \), which implies \( qn_0^0 \equiv pn_1^1 \equiv 0 \pmod{q'} \). The other congruence equations in Eq. 2 follow by similar arguments.

Next, in order to see (ii) \( \Rightarrow \) (i), suppose Eq. 2 holds. If \( \xi_i(0) = t \), then by definition of \( n'_s \), there are distinct suffixes \( i = i_1, \ldots, i_{s_0} \) such that \( \xi_{i_1}(0) = \cdots = \xi_{i_{s_0}}(0) = t \), so that the matrices \( f \circ \xi_{i_1}(0), \ldots, f \circ \xi_{i_{s_0}}(0) \) are equal for each \( f \in \mathbb{Z}_{p,q} \).

On one hand, for \( t \neq 0, 1 \), the number \( n'_0 \) is a multiple of \( q' \) by assumption; on the other hand, if \( t = 0 \) or \( t = 1 \), then \( f \circ \xi_i(0) \) is included in \( M_p \otimes 1_{M_q} \) or \( 1_{M_p} \otimes M_q \) respectively, so the congruence equation \( qn_0^0 \equiv pn_1^1 \equiv 0 \pmod{q'} \) implies the existence of a permutation unitary \( w \) such that \( \text{diag}(f \circ \xi_{i_1}(0), \ldots, f \circ \xi_{i_{s_0}}(0)) = \text{Ad}(w)(a_j \otimes 1_{M_{q'}}) \) for some matrix \( a_j \). Consequently, there is a permutation unitary \( u_0 \in M_{p}', q' \) such that the image of \( \text{Ad}(u_0) \circ ev_0 \circ \varphi \) is included in \( M_{p'} \otimes 1_{M_{q'}} \).

Similarly, we can find a unitary \( u_1 \in M_{q'} \) such that the image of \( \text{Ad}(u_1) \circ ev_1 \circ \varphi \) is included in \( 1_{M_{q'}} \otimes M_{p'} \). Since the unitary group of \( M_{p'} \otimes M_{q'} \) is path-connected, there...
is a unitary $u \in A_{p',q'}$ with $u(0) = u_0$ and $u(1) = u_1$, so that the image of $\text{Ad}(u) \circ \varphi$ is included in $Z_{p',q'}$, as desired.

Finally, suppose that $Z_{p,q}$ is prime. Recalling the construction of the unitary $u$ in the preceding paragraph, and taking the assumption $\zeta_1 \leq \cdots \leq \zeta_q$ into account, we see that the existence of the unitary $v$ in the latter claim follows from the congruence equations
\[
\begin{align*}
  n^0_0(\xi) &\equiv n^0_0(\zeta) \pmod{q'}, \\
  n^1_0(\xi) &\equiv n^1_0(\zeta) \pmod{p'}, \\
  n^0_1(\xi) &\equiv n^0_1(\zeta) \pmod{p'}, \\
  n^1_1(\xi) &\equiv n^1_1(\zeta) \pmod{p'}.
\end{align*}
\]
By what we proved in the preceding paragraphs, we have
\[
qn^0_0(\xi) \equiv pn^0_0(\xi) \equiv 0 \pmod{q'}, \\
qn^0_1(\xi) \equiv pn^0_1(\xi) \equiv 0 \pmod{q'},
\]
and
\[
n^0_0(\xi) + n^0_1(\xi) \equiv k \equiv n^0_0(\zeta) + n^0_1(\zeta) \pmod{q'},
\]
since $n^0_t \equiv 0 \pmod{q'}$ for $t \neq 0, 1$. Consequently, it follows that
\[
\begin{align*}
  p(n^0_0(\xi) - n^0_0(\zeta)) &\equiv p(n^0_1(\xi) - n^0_1(\zeta)) \equiv 0 \pmod{q'}, \\
  q(n^1_0(\xi) - n^1_0(\zeta)) &\equiv q(n^1_1(\xi) - n^1_1(\zeta)) \equiv 0 \pmod{q'},
\end{align*}
\]
and so
\[
\begin{align*}
  n^0_0(\xi) &\equiv n^0_0(\zeta) \pmod{q'}, \\
  n^1_0(\xi) &\equiv n^1_0(\zeta) \pmod{q'},
\end{align*}
\]
since $p$ and $q$ are co-prime. The other equivalences follow similarly, which completes the proof.

We note that every trace on a dimension drop algebra bijectively corresponds to a probability Radon measure on $[0, 1]$, as in the case of $A_q$. The following proposition is an immediate corollary of Lemma 3.1. The proof is the same as Proposition 3.2 so we omit it.

**Proposition 4.3.** Let $\tau$ be a faithful trace on $Z_{p,q}$. Then for any faithful diffuse trace $\sigma$ on $Z_{p,q}$, there is a morphism $\varphi : \langle Z_{p,q}, \tau \rangle \to \langle Z_{p,q}, \sigma \rangle$.

**Proposition 4.4.** Let $p$ and $q$ be co-prime natural numbers. Then there exists $M(p, q) \in \mathbb{N}$ such that if $p'$ and $q'$ are co-prime natural numbers larger than $M(p, q)$ and if $pq$ divides $p'q'$, then for any faithful diffuse measures $\tau, \sigma$ on $[0, 1]$, we can find a morphism $\varphi$ from $\langle Z_{p,q}, \tau \rangle$ into $\langle Z_{p',q'}, \sigma \rangle$.

**Proof.** Let $c, d$ be divisors of $p, q$ respectively. Then, since $c$ and $d$ are co-prime, there exists $N(c, d) \in \mathbb{N}$ such that for any $n \in \mathbb{N}$, one can find $l, m \in \mathbb{N}$ with $(lc + md) < N(c, d)$ and $lc + md \equiv n \pmod{cd}$. We set
\[
M(p, q) := \max_{c|p,d|q} \frac{pq}{cd} N(c, d).
\]

Now suppose that $p', q'$ are co-prime natural numbers larger than $M(p, q)$ and that $pq$ divides $p'q'$. Set $r := p'/(g_{p',q'}g_{p,q'})$ and $s := q'/(g_{p',q'}g_{q,q'})$, where $g_{n,m}$ denotes the greatest common divisor of $n$ and $m$. Note that since $p'$ and $q'$ are co-prime and $pq$ divides $p'q'$, the equations $p = g_{p',p'}g_{p,q'}$ and $q = g_{q',q'}g_{q,q'}$ hold. Since $r > M(p, q)/(g_{p',q'}g_{p,q'}) \geq N(g_{p,q'}, g_{q,q'})$ and similarly $s > N(g_{p',q'}, g_{q,q'})$, we
can find $l_r, m_r, l_s, m_s \in \mathbb{N}$ such that both $r - l_s g_{p,q'} - m_r g_{q,q'}$ and $s - l_s g_{p,q'} - m_r g_{q,q'}$ are positive and can be divided by $g_{p,q'} g_{q,q'}$ and $g_{p,q'} g_{q,q'}$ respectively. We shall put

$$a_0 := l_s g_{p,q'} s, \quad b_0 := rs - a_0,$$

$$a_1 := l_s g_{p,q'} r, \quad b_1 := rs - a_1.$$

Suppose $a_0 > a_1$ and set $c := a_0 - a_1$. We cut $[0, 1]$ into three intervals $I_1 = [0, t_1], I_2 = [t_1, t_2]$ and $I_3 = [t_2, 1]$ so that

$$\tau(I_1) = \frac{a_1 + 1/3}{rs}, \quad \tau(I_2) = \frac{c - 2/3}{rs}, \quad \tau(I_3) = \frac{b_0 + 1/3}{rs}.$$

Let $\tau_i$ be the normalization of $\tau|_{I_i}$. An argument similar to the proof of Lemma 3.1 enables us to find continuous functions $\eta_1, \eta_2, \eta_3$ such that

- $\eta_1$ is a surjection from $[0, 1]$ onto $I_1$ with $\eta_1(0) = \eta_1(1) = 0$ and $(\eta_1)_*(\sigma) = \tau_1$;
- $\eta_2$ is the increasing surjection from $[0, 1]$ onto $[0, 1]$ with $(\eta_2)_*(\sigma) = \frac{1}{n_1}(\tau_1 + \tau_3) + (1 - \frac{2}{n_1})\tau_2$; and
- $\eta_3$ is a surjection from $[0, 1]$ onto $I_3$ with $\eta_3(0) = \eta_3(1) = 1$ and $(\eta_3)_*(\sigma) = \tau_3$.

Then put

$$\xi_i := \begin{cases} 
\eta_1 & \text{if } i = 1, \ldots, a_1, \\
\eta_2 & \text{if } i = a_1 + 1, \ldots, a_0, \\
\eta_3 & \text{if } i = a_0 + 1, \ldots, rs,
\end{cases}$$

and consider the $*$-homomorphism $\varphi: \mathbb{Z}_{p,q} \rightarrow \mathcal{A}_{p,q'}$ defined by

$$\varphi(f) = \text{diag}(f \circ \xi_1, \ldots, f \circ \xi_{rs}).$$

It is not difficult to see from the definition of $\eta_i$ that $\varphi$ is trace-preserving. We shall check that this $\varphi$ satisfies the assumption of Lemma 4.2. Indeed, the functions $\eta_1, \eta_2, \eta_3$ are defined so that the equations

$$n_0^0 = a_0, \quad n_0^1 = b_0, \quad n_0^1 = a_1, \quad n_1^1 = b_1$$

holds, where $n_i^j = n_i^j(\xi)$ is as in Notation 4.1. Now, it follows that

$$q^n_{0} = qa_0 = q^l_r g_{p,q'} s = g_{q,q'} l'q' \equiv 0 \pmod{q'},$$

and

$$pn_0^1 = p(rs - a_0) = p(r - l_s g_{p,q'} - m_r g_{q,q'}) s + pm_r g_{q,q'} s \equiv 0 \pmod{q'}.$$
Proof. It can be easily seen that the proof of Proposition 3.5 works even if $A_n$ and $A_m$ are replaced by $\mathbb{Z}_{p,q}$ and $\mathbb{A}_{p',q'}$ respectively, so one can easily obtain a morphism $\psi$ from $(\mathbb{Z}_{p,q},\tau)$ into $(\mathbb{A}_{p',q'},\sigma)$ with $||\varphi(g) - \psi(g)|| < \varepsilon$ for all $g \in G$. Moreover, a careful reading and a trivial modification of the third paragraph of the proof of Proposition 3.5 enable us to take the unitary $u$ so that $ev_0 \circ \varphi(f) = ev_0 \circ \psi(f)$ and $ev_1 \circ \varphi(f) = ev_1 \circ \psi(f)$ hold for all $f \in \mathbb{Z}_{p,q}$. Therefore, we can take $\psi$ so that its image is included in $\mathbb{Z}_{p',q'}$, which completes the proof. □

Proposition 4.7. Let $\tau, \sigma$ be faithful diffuse measures on $[0, 1]$. Then for any co-prime $p, q \in \mathbb{N}$, there exist co-prime $p', q' \in \mathbb{N}$ and a diagonalizable morphism $\varphi: (\mathbb{Z}_{p,q},\tau) \to (\mathbb{Z}_{p',q'},\sigma)$ such that the images of the maps associated to diagonal expression of $\varphi$ have diameters less than $\varepsilon$.

Proof. The proof is similar to that of Proposition 3.5 but this time, instead of dividing $[0, 1]$ into two intervals $[0, t_0]$ and $[t_0, 1]$, we divide $[0, 1]$ into three intervals $[0, t_0]$, $[t_0, t_1]$ and $[t_1, 1]$ the diameters of which are close to $1/3$, and use Lemma 4.2.

Take integers $l > 2q$, $m > 2p$ so that $p_1 := lp$ and $q_1 := mq$ are co-prime, and set $k := lm$. Then let $r, s$ be natural numbers such that

$r \equiv k \pmod{q_1}, \quad s \equiv k \pmod{p_1}, \quad r + s < k.$

We can always find such $r$ and $s$ because $k = lm > \max\{2p_1, 2q_1\}$. Since $\tau$ is diffuse, there are $t_0 < t_1$ in $(0, 1)$ such that $\tau([0, t_0]) = r/k$ and $\tau([t_1, 1]) = s/k$. Here, we may assume that the diameters of $[0, t_1]$ and $[t_2, 1]$ are arbitrarily close to $1/3$, because $l$ and $m$ can be arbitrarily large and so $q_1/k$ and $p_1/k$ can be arbitrarily small.

Now, put $I_1 := [0, t_0]$, $I_2 := [t_0, t_1]$ and $I_3 := [t_1, 1]$, and let $\tau_i$ be the normalization of $\tau_{I_i}$. By Lemma 3.2, we can find continuous function $\eta_i$ from $[0, 1]$ onto $I_i$ such that

• $\eta_1$ and $\eta_3$ are increasing;
• $\eta_2$ is decreasing; and
• $(\eta_i)_{\sigma} = \tau_i.$

We shall set

$$\xi_j := \begin{cases} \eta_1 & \text{if } j = 1, \ldots, r, \\ \eta_2 & \text{if } j = r + 1, \ldots, k - s, \\ \eta_3 & \text{if } j = k - s + 1, \ldots, k, \end{cases}$$

and check the assumption of Lemma 4.2. Let $n_i = n_i'(\xi)$ be as in Notation 4.1. Then clearly $n_0^0 = n_1^0 = 0$. Also, $q n_i^0 = qr \equiv qk = q_1 l \equiv 0 \pmod{q_1},$
so Eq. \( (2) \) holds, as desired. Consequently, there is a diagonalizable morphism \( \varphi_1 : \langle \mathbb{Z}_{p,q}, \tau \rangle \to \langle \mathbb{Z}_{p',q'}, \sigma \rangle \) such that the ranges of the maps associated to \( \varphi_1 \) have their diameters arbitrarily close to \( 1/3 \). The remaining of the proof is now the same as Proposition \( [3,6] \) so we are done. 

\[ \text{Lemma 4.8. Let } \varphi, \psi \text{ be } *\text{-homomorphisms from } \mathbb{Z}_{p,q} \text{ into } \mathbb{Z}_{p',q'} \text{ of the form} \]

\[ \varphi(f) = \text{Ad}(u)(\text{diag}(f \circ \xi_1, \ldots, f \circ \xi_k)), \]

\[ \psi(f) = \text{Ad}(v)(\text{diag}(f \circ \xi_1, \ldots, f \circ \xi_k)). \]

Then, for any finite subset \( G \subseteq \mathbb{Z}_{p,q} \) and any \( \varepsilon > 0 \), there exists a unitary \( w \in \mathcal{A}_{p',q'} \) such that the inner automorphism \( \text{Ad}(w) \) of \( \mathcal{A}_{p',q'} \) preserves \( \mathbb{Z}_{p',q'} \) and \( \| \text{Ad}(w) \circ \varphi(g) - \psi(g) \| < \varepsilon \) holds for all \( g \in G \).

\[ \text{Proof. Let } \rho \text{ be a the } *\text{-homomorphism from } \mathbb{Z}_{p,q} \text{ into } \mathcal{A}_{p',q'} \text{ defined by} \]

\[ \rho(f) = \text{diag}(f \circ \xi_1, \ldots, f \circ \xi_k), \]

and put

\[ B_s := \text{ev}_s \circ \rho[\mathbb{Z}_{p,q}], \]

\[ C_s^\varphi := \text{ev}_s \circ \text{Ad}(u)[\mathbb{Z}_{p',q'}] \text{ and } C_s^\psi := \text{ev}_s \circ \text{Ad}(v)[\mathbb{Z}_{p',q'}] \]

for \( s = 0, 1 \). Then, \( C_s^\varphi \) and \( C_s^\psi \) are subalgebras of \( \mathcal{A}_{p',q'} \) which are isomorphic to each other, and \( B_0 \) is included in both of them. It is not difficult to find a unitary \( w'_0 \) in the commutant \( \mathcal{B}_0 \)' of \( B_0 \) which induces the isomorphism of \( C_0^\varphi \) onto \( C_0^\psi \).

Now, take \( \delta > 0 \) so that \( |t_1 - t_2| < \delta \) implies \( ||g \circ \xi_i(t_1) - g \circ \xi_i(t_2)|| < \varepsilon/2 \), and let \( w' \) be a unitary in \( \mathcal{A}_{p',q'} \) such that

- \( w'(0) = w'_0 \) and \( w'(1) = w'_1 \);
- \( w'(t) = 1 \) for \( t \in [\delta, 1 - \delta] \); and
- the images of \( w'_{|[0,\delta]} \) and \( w'_{|[1-\delta,1]} \) is included in \( (\mathcal{B}_0)' \) and \( (\mathcal{B}_1)' \) respectively.

Then, clearly the inner automorphism induced by \( w := vw' \) preserves \( \mathbb{Z}_{p',q'} \). Also, for \( g \in G \) and \( t \in [0, \delta] \),

\[ \text{ev}_t \circ \text{Ad}(w) \circ \varphi(g) = \text{Ad}(v(t)w'(t))(\text{diag}(g \circ \xi_1(t), \ldots, g \circ \xi_k(t))) \]

\[ \sim_{\varepsilon/2} \text{Ad}(\nu(t)w'(t))(\text{diag}(g \circ \xi_1(0), \ldots, g \circ \xi_k(0))) \]

\[ = \text{Ad}(\nu(t))(\text{diag}(g \circ \xi_1(0), \ldots, g \circ \xi_k(0))) \]

\[ \sim_{\varepsilon/2} \text{Ad}(\nu(t))(\text{diag}(g \circ \xi_1(t), \ldots, g \circ \xi_k(t))) \]

\[ = \text{ev}_t \circ \psi(g). \]

Similarly, it follows that \( \text{ev}_t \circ \text{Ad}(w) \circ \varphi(g) \sim_{\varepsilon} \text{ev}_t \circ \psi(g) \) if \( t \) is in \([1-\delta, 1]\), and it is obvious that \( \text{ev}_t \circ \text{Ad}(w) \circ \varphi(g) = \text{ev}_t \circ \psi(g) \) if \( t \) is in \([\delta, 1-\delta]\). Consequently, \( \| \text{Ad}(w) \circ \varphi(g) - \psi(g) \| \) is less than \( \varepsilon \) for all \( g \in G \), which completes the proof. \( \square \)

\[ \text{Proposition 4.9. The class } \mathcal{K} \text{ satisfies NAP.} \]
Proof. Let \( \varphi_1, \varphi_2 : \langle \mathbb{Z}_{p,q_0}, \tau_0 \rangle \to \langle \mathbb{Z}_{p,q_1}, \tau_1 \rangle \) be diagonalizable morphisms, \( G \) be a finite subset included in the unit ball of \( \mathbb{Z}_{p,q} \), and \( \epsilon \) be a positive real number. By JEP, it suffices to find morphisms \( \psi_1, \psi_2 \) from \( \langle \mathbb{Z}_{p,q_1}, \tau_1 \rangle \) into some \( \langle \mathbb{Z}_{p,q_2}, \tau_2 \rangle \in \mathcal{K} \) such that \( \| \psi_1 \circ \varphi_1(g) - \psi_2 \circ \varphi_2(g) \| < \epsilon \) holds for all \( g \in G \).

Take \( \delta > 0 \) so that \( |s - t| < \delta \) implies \( \| g(s) - g(t) \| < \epsilon \). As in the proof of Proposition 3.7, we can find a diagonalizable morphism \( \rho \) from \( \langle \mathbb{Z}_{p,q_1}, \tau_1 \rangle \) into some \( \langle \mathbb{Z}_{p,q_2}, \tau_2 \rangle \in \mathcal{K} \), and diagonalizable morphisms \( \Phi_1, \Phi_2 \) from \( \langle \mathbb{Z}_{p,q_0}, \tau_0 \rangle \) into \( \langle \mathbb{Z}_{p,q_1}, \tau_1 \rangle \) with the following properties:

- the inequality \( \| \rho \circ \varphi_1(g) - \Phi_1(g) \| < \epsilon \) holds for all \( g \in G \); and
- there is a diagonal expression
  \[
  \Phi_1(f) = \text{Ad}(u_i)(\text{diag}(f \circ \xi_1^i, \ldots, f \circ \xi_k^i))
  \]
  such that \( \xi_1^i \leq \cdots \leq \xi_k^i \) for each \( i \), and \( \| \xi_j^i - \xi_j^k \| < \delta \) for all \( j \).

By Lemma 4.2 there exists a unitary \( v \in \mathcal{A}_{p,q} \) such that the image of \( \Psi_i := \text{Ad}(u_i) \circ \Phi_i \) is included in \( \mathbb{Z}_{p,q} \). Then by Lemma 4.8 there exists a unitary \( w_j \in \mathcal{A}_{p,q} \) such that the inner automorphism \( \text{Ad}(w_j) \) preserves \( \mathbb{Z}_{p,q} \), and that \( \| \text{Ad}(w_j) \circ \Phi_i(g) - \Psi_i(g) \| < \epsilon \) holds for all \( g \in G \). We put \( \psi_1 := \rho \) and \( \psi_2 := \text{Ad}(w_j^* w_1) \circ \rho \). Then for \( g \in G \), we have

\[
\psi_2 \circ \varphi_2(g) = \text{Ad}(w_j^* w_2) \circ \rho \circ \varphi_2(g)
\]

\[
\sim_\epsilon \text{Ad}(w_j^* w_2) \circ \Phi_2(g)
\]

\[
= \text{Ad}(w_j^* v)(\text{diag}(g \circ \xi_1^2, \ldots, g \circ \xi_k^2))
\]

\[
\sim_\epsilon \text{Ad}(w_j^* v)(\text{diag}(g \circ \xi_1^1, \ldots, g \circ \xi_k^1))
\]

\[
= \text{Ad}(w_j^* \circ \Psi_1(g)
\]

\[
\sim_\epsilon \Phi_1(g)
\]

\[
\sim_\epsilon \psi_1 \circ \varphi_1(g),
\]

which completes the proof. \( \square \)

The following theorem can be shown in almost the same way as Theorem 3.8. We omit details.

Theorem 4.10. The class \( \mathcal{K} \) is a Fraïssé class.

We close this section by showing that the Fraïssé limit of \( \mathcal{K} \) is simple and monotracial. This fact together with [JS99, Theorem 6.2] implies that the Fraïssé limit is indeed the Jiang-Su algebra.

Lemma 4.11. For a measure \( \tau \) on \([0, 1]\), let \( E(\tau) \) be the set of all morphisms from \( \langle \mathbb{Z}_{1,1}, \tau \rangle \) into some \( \langle \mathbb{Z}_{p,q}, \tau' \rangle \in \mathcal{K} \). If \( \tau \) is diffuse and faithful, and if \( \sigma \) is a measure with \( E(\sigma) \supseteq E(\tau) \), then \( \sigma = \tau \).

Proof. Suppose \( \sigma \neq \tau \). Then there exists \( s \in (0, 1) \) with \( \sigma([0, s]) \neq \tau([0, s]) \). If \( \sigma([0, s]) > \tau([0, s]) \), then since \( \tau \) is diffuse there exists \( t > s \) such that \( \sigma([0, s]) = \tau([0, t]) \). Now apply Proposition 3.7 to find a diagonalizable morphism \( \varphi : \langle \mathbb{Z}_{1,1}, \tau \rangle \to \langle \mathbb{Z}_{p,q}, \tau' \rangle \in \mathcal{K} \) such that \( \| \varphi_1 \circ \varphi_2(g) - \Phi_1(g) \| < \epsilon \) holds for all \( g \in G \), and there is a diagonal expression

\[
\Phi_1(f) = \text{Ad}(u_i)(\text{diag}(f \circ \xi_1^i, \ldots, f \circ \xi_k^i))
\]

such that \( \xi_1^i \leq \cdots \leq \xi_k^i \) for each \( i \), and \( \| \xi_j^i - \xi_j^k \| < \delta \) for all \( j \).
\( \langle \mathbb{Z}_{p,q}, \tau \rangle \) such that the images of the maps \( \xi_1, \ldots, \xi_k \) associated to a diagonal expression of \( \varphi \) have diameters less than \((t - s)/3\), and set

\[
S = \{ \xi_i \mid \text{Im} \xi_i \cap [0, s) \neq \emptyset \}, \quad T = \{ \xi_i \mid \text{Im} \xi_i \subseteq [0, t) \}.
\]

Then clearly \( S \subseteq T \), and since \( \varphi \in E(\tau) \subseteq E(\sigma) \), it follows that

\[
\sigma([0, s]) \leq \frac{\#S}{pq} < \frac{\#T}{pq} \leq \tau([0, t]) = \sigma([0, s]),
\]

which is a contradiction. The inequality \( \sigma([0, s]) < \tau([0, s]) \) implies a similar contradiction, so \( \sigma = \tau \).

**Proposition 4.12.** Let \( \langle \mathbb{Z}, \tau \rangle \) be the Fraïssé limit of the class \( \mathcal{X} \). Then \( \tau \) is the unique trace on \( \mathbb{Z} \).

**Proof.** Let \( \sigma \) be a faithful trace on \( \mathbb{Z} \) and suppose \( \sigma \neq \tau \). Then there exists an embedding \( \iota: \mathbb{Z}_{1,1} \rightarrow \mathbb{Z} \) such that \( \iota'(\tau) \neq \iota'(\sigma) \). Now assume \( \varphi: \langle \mathbb{Z}_{1,1}, \iota'(\tau) \rangle \rightarrow \langle \mathbb{Z}_{p,q}, \rho \rangle \) is in \( E(\iota'(\tau)) \), and find a morphism \( \psi: \langle \mathbb{Z}_{p,q}, \rho \rangle \rightarrow \langle \mathbb{Z}, \tau \rangle \). Since \( \langle \mathbb{Z}, \tau \rangle \) is approximately \( \mathcal{X} \)-homogeneous, for any finite \( G \subseteq \mathbb{Z}_{1,1} \) and any \( \varepsilon > 0 \) there exists an automorphism \( \alpha_{G,\varepsilon} \) of \( \langle \mathbb{Z}, \tau \rangle \) such that \( ||\psi \circ \varphi(g) - \iota(g)|| < \varepsilon \) for all \( g \in G \). Set \( \rho'_{G,\varepsilon} := (\psi \circ \alpha_{G,\varepsilon})'(\sigma) \) and let \( \rho' \) be the limit of \( \{\rho'_{G,\varepsilon}\} \) in \( T(\mathbb{Z}_{p,q}) \). Then it is clear that \( \psi: \langle \mathbb{Z}_{1,1}, \iota'(\sigma) \rangle \rightarrow \langle \mathbb{Z}_{p,q}, \rho' \rangle \) is trace-preserving, so \( \varphi \in E(\iota'(\sigma)) \), which is a contradiction.

**Proposition 4.13.** The Fraïssé limit \( \langle \mathbb{Z}, \tau \rangle \) is simple.

**Proof.** Suppose \( I \subseteq \mathbb{Z} \) be a non-trivial ideal. For each embedding \( \iota: \mathbb{Z}_{1,1} \rightarrow \mathbb{Z} \), let \( \Sigma_i \) be the closed subset of \([0, 1]\) which corresponds to the ideal \( I_i := \mathbb{Z}_{1,1} \cap \iota^{-1}[I] \). For each \( \varepsilon > 0 \), choose a function \( f_i^\varepsilon \in I_i \) such that \( |f(t)| \geq \varepsilon \) holds if \( \text{dist}(\iota, \Sigma_i) \geq \varepsilon \). Now, by Proposition 3.7 there exists a diagonalizable morphism \( \varphi \) such that the images of the maps \( \xi_1, \ldots, \xi_k \) associated to a diagonal expression of \( \varphi \) have diameters less than \( \varepsilon \), and as in the proof of Proposition 4.12 we can find an embedding \( \eta: \mathbb{Z}_{1,1} \rightarrow \mathbb{Z} \) which factors through \( \varphi \) and satisfies \( ||\mu(f_i^\varepsilon) - \eta(f_i^\varepsilon)|| < \varepsilon \). Then \( \Sigma_i \) is included in the \( \varepsilon \)-neighborhood of \( \Sigma_i \), since \( \text{dist}(f_i^\varepsilon, I_i) = \text{dist}(\eta(f_i^\varepsilon), I) < \varepsilon \) (see the proof of [Dav96] Lemma III.4.1, for example). On the other hand, clearly \( \Sigma_i \cap \text{Im} \xi_i \) is non-empty for all \( i \), so \( \Sigma_i \) intersects with every \( 4\varepsilon \)-ball. Since this is true for any \( \varepsilon > 0 \) and any \( \iota \), it follows that \( \Sigma_i \) is equal to \([0, 1]\) for any \( \iota \), so \( I = 0 \).

**Acknowledgement.** The author wishes to express his thanks to Professor Ilijas Farah and Professor George Elliott for many stimulating conversations and helpful advices, and Alessandro Vignati for many corrections. The author also would like to thank the Fields Institute for Research in Mathematical Sciences, where the paper is written, for the hospitality.
