On the relation between the monotone Riemannian metrics on the space of Gibbs thermal states and the linear response theory

N. S. Tonchev

Institute of Solid State Physics, Bulgarian Academy of Sciences, 1784 Sofia, Bulgaria

The proposed in J. Math. Phys. v.57, 071903 (2016) analytical expansion of monotone (contractive) Riemannian metrics (called also quantum Fisher information(s)) in terms of moments of the dynamical structure factor (DSF) relative to an original intensive observable is reconsidered and extended. The new approach through the DSF which characterizes fully the set of monotone Riemannian metrics on the space of Gibbs thermal states is utilized to obtain an extension of the spectral presentation obtained for the Bogoliubov–Kubo–Mori metric (the generalized isothermal susceptibility) on the entire class of monotone Riemannian metrics. The obtained spectral presentation is the main point of our consideration. The last allows to present the one to one correspondence between monotone Riemannian metrics and operator monotone functions (which is a statement of the Petz theorem in the quantum information theory) in terms of the linear response theory. We show that monotone Riemannian metrics can be determined from the analysis of the infinite chain of equations of motion of the retarded Green’s functions. Inequalities between the different metrics have been obtained as well. It is a demonstration that the analysis of information-theoretic problems has benefited from concepts of statistical mechanics and might cross-fertilize or extend both directions, and vice versa. We illustrate the presented approach on the calculation of the entire class of monotone (contractive) Riemannian metrics on the examples of some simple but instructive systems employed in various physical problems.
I. INTRODUCTION

During the last five years there is an increasing interest in deriving relations between two seemingly unrelated fields, i.e. the metric space on the set of quantum states (information geometry) and linear response of thermal systems (statistical mechanics) [1–11].

Illustrative example represents such a geometry-based notion as fidelity susceptibility [12] (and refs.therein). It is defined as a coefficient (in front of the second term) in the expansion of a measure of distinguishability between two points on the manifold of density matrices, and as firstly noted in [1] in the ground state is potentially measurable in experiments. To avoid confusion let us note that the fidelity susceptibility appears in various contexts under different names. Namely, it equals to the Bures-Uhlmann metric (based on the symmetric logarithmic derivative (SLD)) which is, however, proportional, up to a factor 1/4, to the minimal quantum Fisher information [13, 14]. More precisely a detail study of the reasons of the break down of the continuity connection between the quantum Fisher information and the Bures metric (or the fidelity susceptibility) has been studied in [15]. Two nonequivalent definitions of fidelity susceptibility have been used in the literature: one based on the Uhlmann’s fidelity (see, e.g. [12]) and another based on “fidelity” introduced in [16] and having a presentation in terms of nonzero temperature Green’s functions [17], see also the Discussion in [18]. Notice that in the ground state both definitions coincides. Equalities that relate zero-temperature fidelity susceptibility and either zero-momentum DSF [1] or negative-two-power moment of DSF [2] make fidelity susceptibility an experimentally measured quantity. In ref. [2] it was announced that the relation between the ground state fidelity susceptibility and the negative-two-power moment of DSF may be extended to the finite temperature case in the spirit of ref. [17]. The major result of ref. [3] is the established frequency integral presentation of the Fisher information through the dissipative part of the dynamic susceptibility. In [3] the scenario that renders density matrices $\rho_1$ and $\rho_2$ distinguishable is due to a unitary transformation generated by a hermitian operator associated with the parameter under estimation.

Thus, in the above cited works, links have been found between two basic geometrical quantities – the quantum Fisher informations regarded as monotone Riemannian metrics, and the dynamical structure factor (DSF) at both zero and finite temperature. The established neat relations unequivocally show that the former is not merely a theory of information topic but may have implications on physical experiments as well.

In informal terms, the underlying idea one follows is to endow the set of quantum states (i.e. the space of density matrices $\rho$) with a metric structure – a smoothly varying positive definite inner product on the tangent spaces at a point $\rho$ and thus explored as a Riemannian manifold, see e.g. [19–21]. Due to the non-commutativity nature of the density matrices there is no unique solution of this problem. In the geometrical approach to statistics, which does distinguish between classical and quantum probabilities, proposed by Morozova and Ďencov [22], and Petz [23] the entire class of the monotone (or contractive) Riemannian metrics (quantum Fisher information(s)) can be introduced and studied from a unified point of view on the basis of the established one-to-one correspondence between the monotone Riemannian metrics (MRM) and a special class of Löwner operator monotone functions. The abundance of metrics raises the interesting question of their potentially importance in the context of quantum statistical mechanics and condensed matter physics. The isothermal susceptibility [24–29] and the quadratic fluctuations (the variance) of a quantum observable [27, 32] are prominent examples that have a clear interpretation in terms of Riemannian geometry on the state of space. Therefore, it seems quite natural a similar relationships to be looked for on the entire class of Riemannian metrics. In fact this point of view has been adopted, albeit in a different way, in refs. [4–6, 29, 30].

It is interesting to make a special comment on the works [4, 5] and [6] because of the obtained complementary results in a common field.

A new presentation of the monotone Riemannian metrics (using the Morozova, Ďencov and Petz classification) in terms of the frequency moments of DSF has been investigated in [4]. This approach allows to evaluate the metrics by an expansion based on the sum rules of the frequency moments of DSF. In some important cases, due to the symmetry properties of the considered model, the proposed expansions may be evaluated in a closed analytical form.

In [5] a generalized version of the fluctuation-dissipation theorem, which relates response functions to generalized covariances (introduced earlier [31] and are nothing but quantum Fisher informations) has been obtained and explored. On the basis of this result a method to determine the generalized covariance from the admittance of the dynamical susceptibility has been developed.

Quite a different approach to quantum correlations which is not motivated by geometrical ideas has been developed in [4]. The quantum Fisher information (QFI) and the quantum variance were considered as members of a wider family of coherence measures. They both quantify the speed of evolution of the state under a unitary transformation, although for different measures of distinguish-ability between the states of the system. At thermal equilibrium, all the coherence measures of this family were expressed in terms of the dynamical susceptibility. As a result a metric approach to phase transitions has been constituted.

It is worth noting that, in the above commented approaches the starting idea and the statistical model which renders the set of density matrices are different. In [4] a term added to the given Hamiltonian which parametrized...
the Gibbs thermal states of the system (Gibbs statistical model) is used, accenting on the relation with statistical mechanics. In [3,6] the family of density matrices is obtained via a unitary transformation generated by a Hermitian operator (unitary statistical model) in the context of the parameter estimation theory, respectively.

In the three works [4,6] notable relations between notions from the linear response theory of quantum statistical mechanics and informational-geometric approach to quantum correlations have been established in quite different aspects. It is the aim of the present study to explore these relations in details focusing on quantum states in exponential form (Gibbs thermal states). Recall that, important relations in the field about the interplay between Hilbert space geometry, thermodynamics and quantum estimation theory have already been studied (see, e.g. refs. [32, 34]).

The paper is organized as follows: In Sectin II some needed notation and basic setting concerning MRM are presented. In Section III we derive a spectral presentation, which allows to relate the entire class of the MRM to linear response functions such as the DSF and the dynamical susceptibility. Based on this relation and using the Green’s functions method, we show in Section IV how to determine the MRM from the dissipative component of the Kubo response function to an external field. In Section V we apply our method to some particular metrics, e.g. Bogoliubov-Kubo-Mori metric, Morozova-Čencov metric, Bures (or SLD) metric and the family of Wigner-Yanase-Dyson metrics. The presentations of these MRM within a thermodynamic setting have been studied which allows to obtain some new inequalities between them. We show the applicability and the efficiency of our method in generating inequalities between different MRM in Section VI. In Section VII the presentation of the MRM in terms of the moments of the dynamical structure factor (DSF) and the relation with the results of Section IV have been discussed. In Section VIII our approach is presented and tested on two models: system of $N$ spins in a constant magnetic field $h$ and a model Hamiltonian which is employed in various physical problems such as the displaced and single-mode squeezed harmonic oscillators. A summary and discussion are given in Section IX. A contains a list of most popular operator monotone functions.

II. NOTATIONS AND BASIC SETTING

A MRM is a family of inner products on the tangent space of a smooth manifold that are used to measure distances on the manifold. For future references, we need to recall briefly the definition of the MRM defined on the differential manifold formed by the quantum statistical density matrices [19–21, 23].

A density matrix $\rho$ (known in the mathematical literature as positive trace-class operator with unit trace-norm, see [52] for a rigorous definition) represents the state of a quantum system associated with a Hilbert space $\mathcal{H}$. For a $n$-dimensional state it is $n \times n$ non-negative trace-one Hermitian matrix. The set of all density matrices under consideration is denoted by

$$\mathcal{D}(\mathcal{H}) = \{\rho(h) \in \mathcal{M}(\mathcal{H}) : \text{Tr}(\rho(h)) = 1, h \in G\},$$

where $\mathcal{M}(\mathcal{H})$ is a differentiable manifold structure connected with the algebra of $n \times n$ matrices $M_n$. Formally $h \in G$, where $G \subset \mathbb{R}$ is an open set including $0$.

For the manifold $\mathcal{M}(\mathcal{H})$ of quantum states, the tangent space $T_\rho \mathcal{D}(\mathcal{H})$ at each point $\rho \in \mathcal{D}(\mathcal{H})$ can be identified with the (real) vector space $\mathcal{B}^+_{2n,a}$ of self-adjoint operators on $\mathcal{H}$ with zero trace: $T_\rho \mathcal{D}(\mathcal{H}) := \{A \in M_n : A = A^+, \text{Tr} A = 0\}$, where $A^+$ denotes the adjoint operator of $A$.

Let us $A$ and $B$ belong to the tangent space $T_\rho \mathcal{D}$ at $\rho$ of the manifold $\mathcal{D}(\mathcal{H})$. The linear mapping $M_n \to M_n$ defined as:

$$L_\rho(A) = \rho A, \quad R_\rho(A) = A \rho, \quad A \in M_n$$

stands for the left and right multiplication by $\rho$. Obviously, $L_\rho R_\rho = R_\rho L_\rho$ considered as matrices in $M_{n^2}$.

Let us define the binary operation on $A$ and $B$

$$m_f(A, B) := A^{1/2} f(A^{-1/2} BA^{-1/2}) A^{1/2}$$

known as the Kubo-Ando operator mean [25], see also Eq. (5.36), Chapter V in ref. [33], where $f(x)$ is an operator monotone function and $\langle A, B \rangle_{HS} := \text{Tr}(A^* B)$ is the Hilbert-Schmidt inner product. Using the notion of matrix mean one may define the class of monotone metrics (called also quantum Fisher informations) parametrized by the functions $f$.

The existence of a wide class of MRM (quantum Fisher informations) on the quantum statistical manifold $\mathcal{D}(\mathcal{H})$ is the essence of the quantum Petz theorem [23] (see also [20, 21]). The theorem states that formula

$$g^f_\rho(A, B) = \langle A, m_f(L_\rho, R_\rho)^{-1}(B) \rangle_{HS},$$

(4)
defines on the family of \(N\) all positive eigenvalues. Note that, from now we shall study (non-singular) full-rank density matrices, i.e. density matrices with literature [19]. In the commutative case, the Bures metric reduces to the classical Fisher information, given by the eigenstate of \(\rho\) adsorbed in \(T\) when the family of density operators is of exponential form [18, 43–46].

We consider a set of Gibbs thermal states characterized by the one-parameter family of density matrices:

\[
\rho(h) = |Z_N(h)|^{-1} \exp[-H(h)],
\]

defined on the family of \(N\)-particles Hamiltonians of the form

\[
H(h) = T - hS,
\]

where the Hermitian operators \(T\) and \(S\) do not commute in the general case. Here, \(h\) is a real (control) parameter, \(Z_N(h) = \text{Tr} \exp[-H(h)]\) is the corresponding partition function and for convenience the inverse temperature \(\beta\) is adsorbed in \(T\) and \(S\). We assume that the Hermitian operator \(T\) has a complete orthonormal set of eigenvectors \(|m\rangle\) with a non-degenerate spectrum \(\{T_m\}; T|m\rangle = T_m|m\rangle\), where \(m = 1, 2, \ldots\) In this basis the zero-field density matrix \(\rho := \rho(0)\) is diagonal:

\[
\langle m|\rho(0)|n\rangle = \delta_{mn}, \quad \rho_m := e^{-T_m}/Z_N(0), \quad m, n = 1, 2, \ldots
\]

In computing the matrix elements \(\langle m|d\rho|n\rangle\), we shall use the formula for the differentiation of an operator function [41] (for a prove in a rigorous mathematical setting, see also [42] and pp. 137-139 in ref. 57)

\[
\frac{\partial}{\partial h} e^{-H(h)} = -\int_0^1 e^{-(1-u)H(h)} \frac{\partial H(h)}{\partial h} e^{-uH(h)} du,
\]

where the operator \(H(h)\) is a function of a parameter \(h\). The identity [12] is an indispensable ingredient of the theory when the family of density operators is of exponential form [18, 43–46].

For the one parameter family of Gibbs state, Eq. (9), \(h = 0\), Eq. (12) immediately gives

\[
\frac{\partial \rho(h)}{\partial h}|_{h=0} = \rho(0) \left[ \int_0^1 e^{T\lambda S} e^{-T\lambda} d\lambda - \langle S \rangle_T \right],
\]
where
\[ \langle \cdots \rangle_T := [Z(T)]^{-1} \text{Tr} \{ e^{-T} \cdots \} \]  
(14)

denotes the thermodynamic mean value.

For the matrix elements of \( d\rho \) (in the eigenbasis of \( \rho \)), one obtains:
\[
|\langle m|d\rho|n\rangle|^2 = |\langle m|\partial_h H(h)|n\rangle|^2 \frac{\ln \rho_n - \ln \rho_m}{\ln \rho_n - \ln \rho_m}, \quad m \neq n, \quad \partial_h = \frac{\partial}{\partial h}
\]  
(15)

and
\[
d\rho_m^2 := |\langle m|d\rho|m\rangle|^2 = \rho_m (|\langle m|S|m\rangle| - \langle S \rangle_T).
\]  
(16)

This result is a consequence of the exponential form of the density matrix and is particularly useful when \( \rho \) is known explicitly. Plugging Eqs. (14) and (22) in Eq. (8) (and explicitly introduce in \( d\rho^2 \) the dependence on \( S \)) one obtains
\[
d^2(S, S) = \frac{1}{4} \left\{ ((\delta S^d)^2)_T + \sum_{m,n,m \neq n} c_f(\rho_m, \rho_n) \left( \frac{\rho_n - \rho_m}{\ln \rho_n - \ln \rho_m} \right)^2 |\langle m|S|n\rangle|^2 \right\}.
\]  
(17)

In Eq. (17), following [33] (see also [17, 18]) for the first term in Eq. (8) we have used the relation
\[
\frac{1}{4} \sum_m d\rho_m^2 \rho_m = \frac{1}{4} ((\delta S^d)^2)_T = \sum_m \rho_m (|\langle m|S|m\rangle| - \langle S \rangle_T)^2,
\]  
(18)

where \( S^d := \sum_m \langle m|S|m\rangle |m\rangle \langle m| \) is the diagonal part of the operator \( S \) and \( \delta S^d := S^d - \langle S^d \rangle_T. \) The expression \( d^2(S, S) \) constitutes Riemannian metrics parametrized by \( f \) on the differentiable manifold \( \mathcal{M}. \)

For our further consideration, it is useful to introduce the family of functions announced in ref. [4]:
\[
g_f(x) := \frac{e^{2x} - 1}{2x} f(e^{2x}) = \frac{1}{2x} \left[ \frac{1}{f(e^{-2x})} - \frac{1}{f(e^{2x})} \right] \geq 0, \quad f \in \mathcal{F}_{op}.
\]  
(19)

Some examples of functions \( g_f(x) \) for operator monotone functions \( f \in \mathcal{F}_{op} \) (see the Appendix) are the following:
\[
g_{\text{Har}}(x) = \frac{\sinh 2x}{2x}, \quad g_{G}(x) = \frac{\sinh x}{x}, \quad g_{B}(x) = \frac{\tanh x}{x},
\]  
(20)

\[
g_{\text{BKM}}(x) = 1, \quad g_{\text{WY}}(x) = \frac{\tanh \frac{1}{2} x}{\frac{1}{2} x}, \quad g_{\text{MC}}(x) = \frac{x}{\tanh x}.
\]

and
\[
g_p(x) = \frac{p}{1-p} x \sinh \frac{p-1}{p} x, \quad -1 \leq p \leq 2,
\]
\[
g_{\text{WYD}}(x) = \frac{1}{2\alpha(\alpha-1)} x \sinh x, \quad 0 \leq \alpha \leq 1.
\]  
(21)

In general, the functions \( g_f(x) \) satisfy the condition \( g_f(x) = g_f(-x) \) and \( g_f(0) = 1. \)

Thus, Eq. (17) can be rewritten as:
\[
d^2(S, S) = \frac{1}{4} \left\{ ((\delta S^d)^2)_T + \sum_{m,n,m \neq n} g_f \left( \frac{1}{2} \ln \frac{\rho_n}{\rho_m} \right) \left( \frac{\rho_n - \rho_m}{\ln \rho_n - \ln \rho_m} \right) |\langle m|S|n\rangle|^2 \right\}.
\]  
(22)

Using that by definition
\[
\lim_{n \to m} \left\{ g_f \left( \frac{1}{2} \ln \frac{\rho_n}{\rho_m} \right) \left( \frac{\rho_n - \rho_m}{\ln \rho_n - \ln \rho_m} \right) \right\} = \rho_m,
\]  
(23)

Eq. (22) may be rewritten in the form
\[
d^2(S, S) = \frac{1}{4} \sum_{m,n} g_f \left( \frac{1}{2} \ln \frac{\rho_n}{\rho_m} \right) \left( \frac{\rho_n - \rho_m}{\ln \rho_n - \ln \rho_m} \right) |\langle m|S|n\rangle|^2 - \langle S \rangle_T^2,
\]  
(24)
which some time is more convenient

Replace \( S \) with \( \delta S := S - \langle S \rangle_T \) in Eq. (21), since \( \langle \delta S \rangle_T = 0 \), one gets

\[
d_f^2(\delta S, \delta S) = d_f^2(S, S),
\]

i.e. the replacement of \( S \) by \( S - \langle S \rangle_T \) does not alter the above definition of \( d_f^2 \). Therefore, when this does not cause confusion, for simplicity, we shall omit the dependence on \( S \) in \( d_f^2 \).

Since \( d_f^2 \) collapse to \( d_{BKM}^2(S, S) \) when \( g_f(x) = g_{BKM}(x) = 1 \), Eq. (22) (or equivalently Eq. (24)) prompts how to obtain a power series expansion of \( d_f^2(S, S) \) in terms on the moments of DSF \( \{4\} \).

Finally, it is easily to obtain the inequalities

\[
g_B(x) \leq g_{MY}(x) \leq g_{BKM}(x) \equiv 1 \leq g_G(x) \leq g_{MC}(x) \leq g_{Har}(x)
\]

which imply inequalities between the different metrics \( d_f(S, S) \). Looking ahead let us notice that the symmetry relation \( g_B(x) = g_{MC}^{-1}(x) \) provides an interesting inequality (see below)

\[
\sqrt{d_B^2(S, S).d_{MC}^2(S, S)} \geq d_{BKM}^2(S, S).
\]

The relation Eq. (22) (or equivalently Eq. (24)) allows us to derive linear response theory type sum-rules that may be useful to bound \( d_f^2(S, S) \).

### III. INTEGRAL PRESENTATION OF \( d_f^2(S, S) \)

After setting the relation

\[
g_f\left(\frac{1}{2} \ln \frac{\rho_n}{\rho_m}\right) \equiv g_f\left(\frac{\omega_{nm}}{2}\right) = \int_{-\infty}^{\infty} g_f\left(\frac{\omega}{2}\right) \delta(\omega - \omega_{nm}) d\omega, \quad \omega_{nm} := T_n - T_m,
\]

into Eq. (22), one gets

\[
d_f^2(S, S) = \frac{1}{4} \left\{ \langle (\delta S)^2 \rangle_T + \sum_{m,n,m \neq n}^{\infty} g_f\left(\frac{\omega}{2}\right) \delta(\omega - \omega_{nm}) \rho_m \left(\frac{1 - e^{-\omega_{nm}}}{\omega_{nm}}\right) |\langle m|S|n\rangle|^2 d\omega \right\}.
\]

In the linear response theory a main notion is the dynamical structure factor (DSF) \(47\) \(51\)

\[
Q_{AB}(\omega) = [Z(T)]^{-1} \sum_{m,n} e^{-T_m} \langle n|A|m\rangle \langle m|B|n\rangle \delta(\omega - \omega_{nm}).
\]

In Eq. (30), in accordance with our initial convention the inverse temperature \( \beta \) is absorbed in the eigenvalues of the operators and we assume the Planck constant \( \hbar = 1 \). We warm the reader that a definition of DSF differs from Eq. (30), e.g.

\[
\tilde{Q}_{AB}(\omega) = 2\pi[Z(T)]^{-1} \sum_{m,n} e^{-T_m} \langle n|A|m\rangle \langle m|B|n\rangle \delta(\omega_{nm} - \omega).
\]

exists in the literature (see \(48\)). If one uses that \( T_n - T_m = \omega \) and hence \( e^{-T_m} = e^{-T_n} e^\omega \), due to the existence of the delta function in the summand of Eq. (30), both definitions are related via the relation

\[
Q_{AB}(\omega) = \frac{1}{2\pi} e^\omega \tilde{Q}_{AB}(\omega).
\]

Notice that in case where the operator \( B = A^+ \), the DSF, for all \( T_n \), is real and positive definite. In our case DSF is relative to the hermitian operator \( S \) and we shall use the notation:

\[
Q_S(\omega) = [Z(T)]^{-1} \sum_{m,n} e^{-T_m} |\langle n|S|m\rangle|^2 \delta(\omega - \omega_{nm}) \geq 0.
\]
Now using Eq. (33) and the result for the thermodynamic mean value of \((\delta S^d)^2\), Eq. (18), one may recast Eq. (29) in the form

\[
d_{f}^2(S, S) = \frac{1}{4} \left\{ \int_{-\infty}^{\infty} g_f \left( \frac{\omega}{2} \right) \left( \frac{1 - e^{-\omega}}{\omega} \right) Q_S(\omega) d\omega - \langle S \rangle_T^2 \right\}.
\]  

Using the symmetry relation (named also detailed balancing relation)

\[
Q_S(\omega) = Q_S(-\omega) e^{\omega}
\]

it is readily seen that the integrand in Eq. (34) is even non-negative function of \(\omega\). Thus, the formula:

\[
d_{f}^2(S, S) = \frac{1}{4} \left\{ 2 \int_{0}^{\infty} g_f \left( \frac{\omega}{2} \right) \left( \frac{1 - e^{-\omega}}{\omega} \right) Q_S(\omega) d\omega - \langle S \rangle_T^2 \right\}.
\]

is an alternative spectral (or Lehmann) presentation of the one to one correspondence between \(d_f^2\) and the standard operator monotone functions \(f\).

Any choice of the standard operator monotone function \(f\) in \(g_f(x)\) generates a different metric. Taking into account that the corresponding integrand in Eq. (36) is continuous and non-negative function for every \(\omega \in [0, \infty]\), the inequalities (26) state that

\[
d_B^2 \leq d_{WY}^2 \leq d_{BK}^2 \leq d_{G}^2 \leq d_{MC}^2 \leq d_{Har}^2.
\]

\[\text{IV. PRESENTATION OF } d_f^2(S, S) \text{ BY GREEN'S FUNCTIONS} \]

Before discussing the problem, let us briefly recall the necessary background concerning the different presentations of the Green’s functions \[48, 50\] we need. Here, we focus on the retarded and advanced Green’s function for any two (non-Hermitian in general) operators \(A(t)\) and \(B(t')\) given by

\[
\langle \langle A, B \rangle \rangle^r(t) = -i\theta(t - t') \langle [A(t), B(t')] \rangle_H
\]

and

\[
\langle \langle A, B \rangle \rangle^a(t') = i\theta(t' - t) \langle [A(t), B(t')] \rangle_H
\]

respectively. Note that \(A(t)\) and \(B(t)\) are in the Heisenberg representation referred to the Hamiltonian of the system \(H\) we are interested in:

\[
A(t) = e^{iHt} A e^{-Ht}, \quad B(t) = e^{iHt} B e^{-Ht}.
\]

The Heaviside step function \(\theta(t - t')\) emerged as a natural consequence of causality. The Fourier transform of the retarded and advanced Green’s functions are given by

\[
\langle \langle A, B \rangle \rangle^r_\omega = \langle \langle A, B \rangle \rangle_{\omega + 0^+} = \mathcal{P} \int_{-\infty}^{\infty} Q_{AB}(\omega') (1 - e^{-\omega'}) \frac{1}{\omega - \omega'} d\omega' - i\pi(1 - e^{-\omega}) Q_{AB}(\omega)
\]

and

\[
\langle \langle A, B \rangle \rangle^a_\omega = \langle \langle A, B \rangle \rangle_{\omega - 0^+} = \mathcal{P} \int_{-\infty}^{\infty} Q_{AB}(\omega') (1 - e^{-\omega'}) \frac{1}{\omega - \omega'} d\omega' + i\pi(1 - e^{-\omega}) Q_{AB}(\omega),
\]

respectively. The symbol \(\mathcal{P}\) indicate that the principal value must be taken in the integrals.

One can obtain that \(\langle \langle A, B \rangle \rangle^r_\omega\) satisfies the algebraic equation

\[
\omega' \langle \langle A, B \rangle \rangle^r_\omega = \frac{i}{2\pi} \langle \langle A, B \rangle \rangle + \langle \langle [C, H], B \rangle \rangle^r_\omega,
\]

where \(C = [A, H]\).

Let us introduce the complex-valued function

\[
\langle \langle A, B \rangle \rangle_E = \int_{-\infty}^{\infty} d\omega Q_{A,B}(\omega) \frac{1 - e^{-\omega}}{E - \omega}.
\]
The function $\langle\langle A, B \rangle\rangle$ is holomorphic on the complex E-plane with cut along the real axis. We are now in position to apply the Bogoliubov and Tyablikov spectral relation \[52\]

$$(1 - e^{-\omega})Q_{A,B}(\omega) = \frac{i}{2\pi} \left\langle \langle A, B \rangle \rangle_{\omega+\imath\epsilon} - \langle\langle A, B \rangle\rangle_{\omega-\imath\epsilon} \right\rangle$$

in order to transfer the computational problem in Eq. (34) in the realm of the Green’s functions method. For $A = B = \delta S$, where the product of the two matrix elements in $Q_{SS}(\omega)$ in the integrand of Eqs. (41) and (42) is real, the function $\langle\langle A, B \rangle\rangle_{\omega+\imath\epsilon}$ is the complex conjugate of the function $\langle\langle A, B \rangle\rangle_{\omega-\imath\epsilon}$. In this particular case,

$$\pi(1 - e^{-\omega})Q_{SS}(\omega) = -\text{Im}\langle\langle S, S \rangle\rangle^r_{\omega},$$

(here $\omega$ is a real quantity) and after plugging Eq. (46) in Eq. (34) the following relation holds:

$$d^2f_{SS}(\delta S, \delta S) = \frac{1}{4} \left\{ \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{1}{\omega} \text{g}_{\omega}\left(\frac{\omega}{2}\right) \text{Im}\langle\langle S, S \rangle\rangle^r_{\omega} d\omega \right\}.$$}

The explicit determination of the Green’s functions or, equivalently, of the DSF generally requires the full solution of the infinite chain of equations, Eq. (43), or the solution of the Schrödinger equation, yielding the eigenvalues of the Hamiltonian and matrix elements of Eq. (33). In most interacting systems, the solution of Eqs. (43) is a difficult task that can usually be accomplished only approximately.

We show that monotone Riemannian metrics can be determined from an analysis of the equation of motion of the retarded Green’s function. An alternative way is based on the analysis of Green’s functions using Feynman diagrams. Let us recall the relation \[48, 51\]:

$$\chi''_{S}(\omega) = \pi(1 - e^{-\omega})Q_{SS}(\omega).$$

Thus Eq. (47) may be presented as

$$d^2f_{SS}(\delta S, \delta S) = \frac{1}{4} \left\{ \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{1}{\omega} \text{g}_{\omega}\left(\frac{\omega}{2}\right) \chi''_{S}(\omega) d\omega \right\}.$$}

Here, it is useful to recall that $\chi''_{S}(\omega)$ is a real odd function.

V. PRESENTATION OF $d^2f_{SS}(S, S)$ WITHIN A THERMODYNAMIC SETTING AND SOME PARTICULAR INEQUALITIES

In order to establish the neat relation of Eq. (50) with some thermodynamic quantities and inequalities we shall consider the following important particular cases:

A. The Bogoliubov-Kubo-Mori function $f_{BKM}(x) = \frac{1}{1+x}$

Let us define the Bogoliubov-Duhamel inner product \[24, 25, 28, 29, 53–55\] (which is often called Bogoliubov-Kubo-Mori scalar product or canonical correlation) for the operators $A$ and $B$ by the formula:

$$F_0(A; B) := \int_0^1 d\tau \langle e^{\tau T} A^+ e^{-\tau T} B \rangle_T = \frac{1}{2} \sum_{m,n,m \neq n} |\langle n| A^+ |m \rangle \langle n| B |m \rangle| \frac{\rho_n - \rho_m}{X_{mn}} + \sum_n \rho_n |\langle n| A^+ |n \rangle \langle n| B |n \rangle|.$$}

Note that $F_0(\delta S; \delta S)$ is an important ingredient of the linear response theory, and is exactly the isothermal susceptibility associated with $\hbar$, $\chi(h=0)$

$$\chi_{h=0} = F_0(\delta S; \delta S) = \frac{1}{\pi} \int_{-\infty}^{\infty} \omega^{-1} \chi''_{S}(\omega) d\omega.$$
In this case $g_{BKM}(\omega/2) = 1$. From Eq. (54) we obtain the well known result:

$$d_{BKM}^2(S, S) = \frac{1}{4} F_0(\delta S; \delta S), \quad \delta S = S - \langle S \rangle_T. \tag{53}$$

From the other side, from Eq. (50) one gets

$$d_{BKM}^2(S, S) = \frac{1}{8\pi} \int_{-\infty}^{\infty} (\omega)_{-1} \chi_S''(\omega) d\omega = \frac{1}{4} \chi(h=0). \tag{54}$$

Using the idea of so called generalized or deformed metrics, the physical interpretation of the Bogoliubov-Kubo-Mori metric as an integral (global) characteristic of the one-parameter family of Wigner-Yanase-Dyson metrics was clarified and its intermediate position between extremal metrics was analyzed in ref. [29]. For more details one can see also ref. [30].

B. The Morozova-Čencov function $f_{MC}(x) = (\frac{x-1}{\ln x})^2 \frac{2}{1+x}$

Note that the subscript $MC$ means that the operator monotone function $f_{MC}$ was introduced by Morozova and Čencov [22]. In this case, plugging $g_{MC}(\frac{\omega}{2}) = \frac{\omega^2}{2 \tanh \omega/2}$ in Eq. (54) with the help of the identity

$$\tanh \frac{\omega}{2} = \frac{1 - e^{-\omega}}{1 + e^{-\omega}} \tag{55}$$

and Eq. (55) we obtain [4]:

$$d_{MC}^2(S, S) = \frac{1}{4} (\langle S - \langle S \rangle_T \rangle^2)_T. \tag{56}$$

From the other side, combining Eq. (50) with Eq. (56) one gets the relation:

$$\langle S^2 - \langle S \rangle_T^2 \rangle_T = \frac{1}{2\pi} \int_{-\infty}^{\infty} \chi_S''(\omega) \coth \left(\frac{\omega}{2}\right) d\omega \tag{57}$$

also known as the Callen-Welton fluctuation-dissipation theorem (see, e.g. [48, 51]).

If operators $T$ and $S$ commute, one can see from Eq. (61) that $d_{BKM}^2$ and $d_{MC}^2$ coincides. It is instructive to consider the difference between the total fluctuations of an observable $\langle S^2 - \langle S \rangle_T^2 \rangle_T$ and its thermal fluctuations $F_0(\delta S; \delta S)$ studied in refs. [4, 44, 50, 57]. This difference called “quantum variance” is studied in ref. [44], in a slightly modified version of the exponential model given by Eq. (9), it was demonstrated that the strictly classical fluctuations in $S$ constrain the achievable precision in estimates of $h$.

In the context of the Riemannian metrics the corresponding expression (in our notation) is [53, 57]:

$$d_{MC}^2(S, S) - d_{BKM}^2(S, S) = \frac{1}{8\pi} \int_{-\infty}^{\infty} \chi_S''(\omega) \left(\frac{\omega}{2}\right)^{-1} \left[ g_{ff} \left(\frac{\omega}{2}\right) - 1 \right] d\omega. \tag{58}$$

The above equation is a particular case of $f = f_{MC}$ of the more general relation

$$d_{f}^2(S, S) - d_{BKM}^2(S, S) = \frac{1}{8\pi} \int_{-\infty}^{\infty} \chi_S''(\omega) \left(\frac{\omega}{2}\right)^{-1} \left[ g_{ff} \left(\frac{\omega}{2}\right) - 1 \right] d\omega. \tag{59}$$

The explicit determination of the rhs of Eq. (59) requires the knowledge of $\chi_S''(\omega)$ which in itself is a difficult task. It is shown [4, 50, 57] that the rhs of Eq. (55) lends itself to analysis based on the Feynman path-integral representation as well to numerical Monte-Carlo based analysis.

It is worth noting that in ref. [4] the deviation of any monotone Riemannian metric $d_{f}^2(S, S)$ from $d_{BKM}^2(S, S)$ (or $d_{MC}^2(S, S)$) has been presented as a series expansion in terms of the moments of DSF relative to the operator $S$ (see also below). An useful information may be obtained by some thermodynamic inequalities as well. Different choices of the upper bound on the rhs of Eq. (58) may generate different thermodynamic inequalities [53, 58]. For example the application of the elementary inequality

$$1 \leq x \coth x \leq 1 + \frac{1}{3} x^2 \tag{60}$$
to the rhs of Eq. (58) immediately yields
\[ 0 \leq d_{MC}^2(S, S) - d_{BKM}^2(S, S) \leq \frac{1}{48\pi} \int_{-\infty}^{\infty} \chi'' S(\omega) \omega d\omega = \frac{1}{48} \langle [[S, T]_-, S]_- \rangle_T, \]
(61)
which is a reminiscent of the well known thermodynamic inequality of Brooks Harris [59] (see also [53]).

C. The Bures function \( f_B(x) = \frac{x+1}{x} \)

In this case \( g_B(\omega/2) = \frac{\tanh \omega/2}{\omega/2} \), and one has the expression (named also Bures metric or fidelity susceptibility, see e.g. [18, 43, 60, 61]):
\[ d_B^2(S, S) = \frac{1}{2} \left\{ \int_{-\infty}^{\infty} \frac{\tanh(\omega/2)}{\omega} \left( \frac{1 - e^{-\omega}}{\omega} \right) Q_{4S}(\omega) d\omega \right\}. \]
(62)

With the help of the fluctuation-dissipation theorem, Eq. (49), from Eq. (62) one gets
\[ d_B^2(S, S) = \frac{1}{8\pi} \int_{-\infty}^{\infty} \left( \frac{\omega}{2} \right)^{-2} \tanh \left( \frac{\omega}{2} \right) \chi'' S(\omega) d\omega, \]
(63)
(see also [53]).

A similar expression to Eq. (58) holds for \( d_B^2(S, S) \) instead of \( d_{MC}^2(S, S) \):
\[ d_{BKM}^2(S, S) - d_B^2(S, S) = \frac{1}{8\pi} \int_{-\infty}^{\infty} \chi'' S(\omega) \left( \frac{\omega}{2} \right)^{-1} \left[ 1 - \left( \frac{\omega}{2} \right)^{-1} \coth^{-1} \left( \frac{\omega}{2} \right) \right] d\omega. \]
(64)

An alternative presentation of \( d_B^2(S, S) \) in terms of the thermodynamic mean values of successively higher commutators of the Hamiltonian with the operator involved through the control parameter (e.g. \( h \)) is given in [61]:
\[ d_{BKM}^2(S, S) - d_B^2(S, S) = 2 \sum_{l=1}^{\infty} \frac{2^{2l+2}}{(2l+2)!} B_{2l+2}(R_{2l-1}R_0)_T, \]
(65)
where the iterated commutators (see, also subsection VII A bellow) \( R_n \equiv R_n(S) = [T, R_{n-1}(S)], \ n = 1, 2, \ldots \) and \( B_{2n} \) are the Bernoulli numbers.

The equivalence of Eq. (65) and Eq. (64) may be obtained with the help of the the relation
\[ (R_{2l-1}R_0)_T = -M_{2l-1}(S), \]
(66)
where \( M_{2l-1}(S) \) are the moments of the DSF (see Eq. (69) in the next subsection VII B).

From Eq. (64), with the help of the elementary inequality
\[ 1 - \frac{1}{3} x^2 \leq (x \coth x)^{-1} \leq 1, \]
(67)
immediately follows
\[ 0 \leq d_{BKM}^2(S, S) - d_B^2(S, S) \leq \frac{1}{48\pi} \int_{-\infty}^{\infty} \chi'' S(\omega) \omega d\omega = \frac{1}{48} \langle [[S, T]_-, S]_- \rangle_T. \]
(68)

The above inequalities first were proven in [18] in terms of the fidelity susceptibility, where their usefulness is illustrated by two examples: the Dicke model of superradiance and singe-impurity Kondo model. The lhs of (58) was proven also in [44] and used to to obtain a new uncertainty relation between energy and temperature for a quantum system strongly interacting with a reservoir.

Finally, for the difference
\[ d_{MC}^2(S, S) - d_B^2(S, S) = \frac{1}{8\pi} \int_{-\infty}^{\infty} \chi'' S(\omega) \left( \frac{\omega}{2} \right)^{-1} \left[ \frac{\omega/2}{\tanh(\omega/2)} - \frac{\tanh(\omega/2)}{\omega/2} \right] d\omega. \]
(69)
with the help of the inequality

\[
0 \leq \frac{x}{\tanh x} - \frac{\tanh x}{x} \leq \frac{2}{3}x^2
\]

one obtains the inequality

\[
0 \leq d_{MC}^2(S,S) - d_B^2(S,S) \leq \frac{1}{24} \langle [[S,T],S,]_T \rangle.
\]

If the Brook Harris inequality \((61)\) imposes a restriction on the isothermal susceptibility \(\chi_{h=0} = 4d_{BKM}^2(S,S)\) then \((71)\) is its counterpart for the fidelity susceptibility \(\chi_F = 4d_B^2(S,S)\).

D. The Wigner-Yanase-Dayson function

The Wigner, Yanase and Dyson (WYD) skew information \((62)\) (see also \((63)\) and refs. therein) is given by

\[
I_{WYD}^f(\rho, S) := -\frac{1}{2}[Z(T)]^{-1}\text{Tr} \left( [e^{-\alpha T}, S^+] \times [e^{-(1-\alpha) T}, S^-] \right), \quad 0 \leq \alpha \leq 1.
\]

Here, we use the superscript \(f_{WYD}\) to stress that \(I_{WYD}^f(\rho, S)\) is related to the standard operator monotone function

\[
f_{WYD} \equiv f_{WYD}(\alpha, x) = \alpha(\alpha - 1) \frac{(x - 1)^2}{(x^\alpha - 1)(x^{1-\alpha} - 1)}, \quad 0 < \alpha < 1.
\]

The WYD-skew information can also be written as

\[
I_{WYD}^f(\rho, S) = \text{Tr}\{\rho S^2\} - \text{Tr}\{\rho^\alpha S\rho^{1-\alpha} S\}.
\]

One may observe that

\[
\frac{1}{4} \int_0^1 I_{WYD}^f (\rho, S) d\alpha = d_{MC}^2(S,S) - d_B^2(S,S) \leq \frac{1}{48\pi} \int_{-\infty}^\infty \chi''(\omega) \omega d\omega = \frac{1}{48} \langle [[S,T],S,]_T \rangle,
\]

and thus (see Eq. \((61)\))

\[
\int_0^1 I_{WYD}^f (\rho, S) d\alpha \leq \frac{1}{12\pi} \int_{-\infty}^\infty \chi''(\omega) \omega d\omega = \frac{1}{48} \langle [[S,T],S,]_T \rangle.
\]

A generalization of Eq. \((72)\) (introduced in ref. \([64]\) as a “metric adjusted skew information”) is given (in our notations) by

\[
I^f(\rho, S) = \frac{f(0)}{2} \sum_{m,n} \left( \frac{\rho_m - \rho_n}{\rho_n f(\rho_m/\rho_n)} \right) |\langle m|S|n\rangle|^2;
\]

where \(f \in F_{op}\) is an arbitrary standard operator monotone function with \(f(0) \neq 0\), see also \([20]\). Plugging Eq. \((73)\) in Eq. \((77)\) one obtains as a particular case the WYD-skew information given by Eq. \((72)\).

Here, we shall consider a set of Gibbs states characterized by the family of density matrices given by

\[
\rho(h) = [Z_N(h)]^{-1} \exp[-H(h, R_1)],
\]

defined on the family of \(N\)-particles Hamiltonians of the form

\[
H(h) = T - h R_1, \quad R_1 := [T, S].
\]

where the Hermitian operators \(T\) and \(S\) do not commute. Formally, replacing \(S\) by \(R_1\) in Eq. \((24)\) after a straightforward calculation one obtains

\[
d_f^2(S,S) := d_f^2(R_1, R_1) = \frac{1}{4} \left\{ \sum_{m,n} g_f \left( \frac{1}{2} \ln \frac{\rho_n}{\rho_m} \right) \left( \frac{\rho_n - \rho_m}{\ln \rho_n - \ln \rho_m} \right) \left( \ln \frac{\rho_n}{\rho_m} \right)^2 \right\},
\]

where \(g_f\) is an arbitrary standard operator monotone function with \(g_f(0) \neq 0\), see also \([20]\).
where the symbol “tilde” is used to emphasize the change of the statistical model, i.e. Eq. 78 instead of Eq. 9. Comparing Eq. (77) and Eq. (80) one obtains

\[ \frac{1}{4} I^f (\rho, S) = \frac{f(0)}{2} D_f^2 (S, S). \]  

(81)

Recall that the same relation (up to the irrelevant multiplier 1/4) by definition holds between WYD-skew information and QFI (see Definition 1.2 in [64]).

If one strictly follows the reasoning of Section IV, the following result for \( \tilde{d}_f^2 (S, S) \) takes place

\[ \tilde{d}_f^2 (S, S) = \frac{1}{4} \left\{ \frac{1}{\pi} \int_{-\infty}^{\infty} \omega g_f \left( \frac{\omega}{2} \right) \chi''_S (\omega) d\omega \right\}. \]  

(82)

Plugging Eq. (82) in Eq. (81) one gets

\[ I^f (\rho, S) = \frac{f(0)}{2 \pi} \int_{-\infty}^{\infty} \omega g_f \left( \frac{\omega}{2} \right) \chi''_S (\omega) d\omega. \]  

(83)

Formally, this result coincides with Eq. (40) of ref. [3]. The difference is hidden in the physical meaning of \( \chi''_S \) where the external perturbation of a special type, i.e. \( R_1 \) is applied.

If we consider the standard operator monotone function given by Eq. (73) then the metric adjusted skew information is

\[ I^{wYD} (\rho, S) = \frac{1}{2} \left\{ \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{\cosh(\omega/2) - \cosh[(1 - 2\alpha)\omega/2]}{\sinh(\omega/2)} \chi''_S (\omega) d\omega \right\}, \]

or using Eq. (57)

\[ I^{wYD} (\rho, S) = \langle S^2 - \langle S \rangle^2 \rangle_T + \frac{1}{2} \left\{ \frac{1}{\pi} \int_{-\infty}^{\infty} \frac{\cosh[(1 - 2\alpha)\omega/2]}{\sinh(\omega/2)} \chi''_S (\omega) d\omega \right\}. \]  

(84)

(85)

Integrating the above equation over \( \alpha \) one obtains (with the help of Eq. (53)) the well known result for the WYD-skew information

\[ \int_0^1 I^{wYD} (\rho, S) d\alpha = \langle S^2 - \langle S \rangle^2 \rangle_T - F_0((\delta S; \delta S)), \]  

or for the metrics

\[ \frac{1}{8} \int_0^1 \tilde{d}_f^{wYD} (S, S) d\alpha = d_{MC}(S, S) - d_{BKM}(S, S). \]  

(86)

(87)

**VI. APPLICATIONS OF THE INTEGRAL PRESENTATION: GENERAL INEQUALITIES**

For any two (non-Hermitian in general) operators \( \delta A = A - \langle A \rangle_T \) and \( B = A - \langle B \rangle_T \) let us define

\[ P_{A:B} (\omega) = (1 + e^{-\omega}) Q_{\delta A, \delta B} (\omega), \]  

(88)

where

\[ Q_{\delta A, \delta B} (\omega) = [Z(T)]^{-1} \sum_{m,n} e^{-T_m} \langle n | \delta A | m \rangle \langle m | \delta B | n \rangle \delta(\omega - \omega_{nm}). \]

Thus a straightforward generalization of our formula (54) is:

\[ \tilde{d}_f^2 (\delta A, \delta B) = \frac{1}{4} \left\{ \frac{1}{2} \int_{-\infty}^{\infty} \left( \frac{\omega}{2} \right)^{-1} \tanh \left( \frac{\omega}{2} \right) g_f \left( \frac{\omega}{2} \right) P_{A:B} (\omega) d\omega \right\}. \]  

(89)

It is easy to check that \( P_{\delta A, \delta B} (\omega) \) defines a scalar product in the space of operators \( \delta A \) and \( \delta B \) and satisfies the Cauchy-Schwarz inequality in the form (at this point we utilize the idea of ref. [62])

\[ \left| \int_{-\infty}^{\infty} G_{A}^f (\omega) \tilde{G}_{B}^f (\omega) P_{A:B} (\omega) d\omega \right|^2 \leq \int_{-\infty}^{\infty} |G_A^f (\omega)|^2 P_{A:A} (\omega) d\omega \int_{-\infty}^{\infty} |G_B^f (\omega)|^2 P_{B:B} (\omega) d\omega, \]  

(91)
for any two functions (complex in general) \( G^f_A(\omega) \) and \( G^f_B(\omega) \) labeled by the operators \( A \) and \( B \) and the standard operator monotone functions \( f(\omega) \) and \( \tilde{f}(\omega) \).

A.) Let us define

\[ \tilde{f}(x) = \sqrt{f(x)\tilde{f}(x)}, \]  

where \( \tilde{f}(x), f(x) \) and \( \tilde{f}(x) \) are standard operator monotone functions. By setting

\[ G^f_A(\omega) = \left(\frac{\omega}{2}\right)^{-1/2} \left[ \tanh\left(\frac{\omega}{2}\right) g_f(\omega/2) \right]^{1/2}, \]
\[ G^f_B(\omega) = \left(\frac{\omega}{2}\right)^{-1/2} \left[ \tanh\left(\frac{\omega}{2}\right) g_f(\omega/2) \right]^{1/2} \]  

in (91), one gets the inequality

\[ \left| \int_{-\infty}^{\infty} \left[ \tanh\left(\frac{\omega}{2}\right) g_f(\omega/2) \right] P_{A:B}(\omega)d\omega \right|^2 \]
\[ \leq \int_{-\infty}^{\infty} \left[ \tanh\left(\frac{\omega}{2}\right) g_f(\omega/2) \right] P_{A:A}(\omega)d\omega \times \int_{-\infty}^{\infty} \left[ \tanh\left(\frac{\omega}{2}\right) g_f(\omega/2) \right] P_{B:B}(\omega)d\omega. \]  

Thus, using Eq. (90), one obtains

\[ |d_f^2(\delta A, \delta B)|^2 \leq d_f^2(\delta A, \delta A)d_f^2(\delta B, \delta B), \]  

It is readily seen that if \( A = B = S \) and all three functions \( \tilde{f}(x), \tilde{f}(x) \) and \( f(x) \) are standard operator monotone functions obeying the functional relation Eq. (92), inequality (95) generates inequalities between Riemannian metrics. The geometric mean of two operator monotone functions is still an operator monotone function in the following important cases:

\[ f_{BKM}(x) = \sqrt{f_B(x)f_{MC}(x)}; \quad f_{G}(x) = \sqrt{f_B(x)f_{Har}(x)}, \]

where \( f_G(x) := \sqrt{\omega} \), and thus the inequalities are true:

\[ d^2_G \leq (d^2_B \cdot d^2_{Har})^{1/2} \]  

and

\[ d^2_{BKM} \leq (d^2_B \cdot d^2_{MC})^{1/2}. \]  

Let us note that inequalities (97) and (98) are stronger than \( d^2_G \leq d^2_{Har} \) and \( d^2_{BKM} \leq d^2_{MC} \), respectively.

B.) We do remark that a particular realization of the Eq. (92) takes place for the both monotone operator functions \( f_{\frac{1}{2} - d}(x) \) and \( f_{\frac{1}{2} + d}(x) \) defined by Eq. (92), and \( f_G(x) \) (98). Then it is easily verified that from Eq. (92) one gets the relation

\[ g_{\frac{1}{2} - d}(x)g_{\frac{1}{2} + d}(x) = \frac{\sinh^2(x)}{x^2} \equiv [g_G(x)]^2. \]  

As a result the Cauchy-Schwartz inequality (94) implies the inequality

\[ d^2_G \leq \left( d^2_{\frac{1}{2} - d} \cdot d^2_{\frac{1}{2} + d} \right)^{1/2}, \quad 0 \leq d \leq \frac{3}{2}. \]  

C.) By setting

\[ G_A(\omega) = \left(\frac{\omega}{2}\right)^{-1} \tanh\left(\frac{\omega}{2}\right) \left[ g_f(\omega/2) \right]^{1/2}, \quad G_B(\omega) = \left[ g_f(\omega/2) \right]^{1/2}, \]
one gets
\[
|d_f^2(\delta A, \delta B)|^2 \leq \int_{-\infty}^{\infty} [(\omega/2)^{-2} \tanh^2(\omega/2) g_f(\omega/2)] P_{A;A}(\omega) d\omega \int_{-\infty}^{\infty} [g_f(\omega/2)] P_{B;B}(\omega) d\omega,
\]
(102)
or if \( A = B = S \) and \( f = f_{BKM} \) one gets
\[
d^2_{BKM} \leq (d^2_B \cdot d^2_{MC})^{1/2},
\]
(103)
or if \( A = B = S \) and \( f = f_B \) one gets
\[
d^2_B \leq (d^2_{BKM})^{1/2} \left\{ \int_{-\infty}^{\infty} \left[ \frac{\tanh(\omega/2)}{\omega/2} \right] P_{B;B}(\omega) d\omega \right\}^{1/2},
\]
(104)
The application of the inequality \((x \coth x)^{-1} \leq 1\) to Eq. (90) readily gives the following upper bound:
\[
d_f^2(\delta A, \delta B) \leq \frac{1}{4} \left\{ \frac{1}{2} \int_{-\infty}^{\infty} g_f(\omega/2) P_{A,B}(\omega) d\omega \right\},
\]
(105)
which becomes an identity in the classical regime of high temperature where \( \coth(\omega/2) \to \omega/2 \) in (90) (recall that the inverse temperature is absorbed in \( \omega \)).

In the particular case of Bures metric, \( g_B(x) = \omega^{-1} \tanh x \), from the above inequality one gets \[18\]
\[
d^2_B(\delta A, \delta B) \leq \frac{1}{4} \left\{ \frac{1}{2} \int_{-\infty}^{\infty} g_B(\omega/2) P_{A,B}(\omega) d\omega \right\} = d^2_{BKM}(\delta A, \delta B),
\]
(106)
in consistent also with (104).

VII. MONOTONE RIEMANNIAN METRICS (QUANTUM FISHER INFORMATIONS) WITHIN THE SET DEFINED BY REF. [4]

In this Section, first we shall review how ref. [4] relates the entire class of MRM to the moments of DSF. Thus, useful information of their behavior is given in terms of the thermodynamic mean values of iterated commutators of the considered Hamiltonian \( T \) with the operator \( S \) involved through the control parameter \( h \). After reviewing the result of ref. [4], we shall connect the results of present study to that of [4].

A. Summary of the basic results of ref. [4]

Let us introduce the moments of the DSF:
\[
M_p(S) := \int_{-\infty}^{+\infty} d\omega \omega^p Q_S(\omega), \quad p = -1, 0, 1, 2, \ldots
\]
(107)
It is possible to check that
\[
M_{p-1}(S) = 2^{-1} F_p(S; S), \quad p = 0, 1, 2, \ldots
\]
(108)
(for details see [4]), where the functionals \( F_n(S; S) \) :
\[
F_p(S; S) := 2^{n-1} \sum_{ml} |\langle m|S|l\rangle|^2 |\rho_l - (-1)^p \rho_m| \cdot |X_{ml}|^{n-1},
\]
(109)
have been introduced in [53] as a generalization of the Bogoliubov - Duhamel inner product \( F_0(S; S) \), see above the Eq. (51). It is convenient to use the following basis independent presentations of \( F_n(S; S) \) [4, 61] :
\[
F_p(S; S) = 2(-1)^{p+1} \langle R_{p-1} R_0 \rangle_T, \quad p = 0, 1, 2, \ldots
\]
(110)
The notion of iterated commutators (named also nested commutators)

\[ R_0 \equiv R_0(S) \equiv S, \quad R_1 \equiv R_1(S) := [T, S], \ldots, \]

\[ R_p \equiv R_p(S) := [T, R_{p-1}(S)], \quad p = 0, 1, 2, \ldots, \]

is introduced. By definition \( R_{-1} \equiv X_{ST} \) is a solution of the operator equation

\[ S = [T, X_{ST}] \ldots. \quad (112) \]

Eqs. (108) are not but the well known sum rules for the moments of the DSF in the linear response theory (see, e.g., [47–49, 51]). Note that Eqs. (108) provide an algebraic way to evaluate the moments of the DSF.

**Main results.** The main results concern two series expansions of \( d^2_f \) which quantify the deviation of any one member of the family \( d^2_f \) from \( d^2_{BKM} \) or \( d^2_{MC} \), respectively.

The following formulas are valid [4]:

A.)

\[
\frac{d^2_f}{dS,dS} = \left\{ \frac{d^2_{BKM}}{dS,dS} + \frac{1}{4} \sum_{l=1}^{\infty} \left( \frac{1}{2} \right)^{2l-1} a_{2l-1}(f) M_{2l-1}(S) \right\}, \quad (113)
\]

where the formal series expansion of the family of functions \( g_f(x) \):

\[
g_f(x) = 1 + \sum_{l=1}^{\infty} a_{2l-1}(f)(x)^{2l} \quad (114)
\]

defines the infinite sequence of coefficients (which depend on \( f \)) \( a_{2l-1}(f), l = 1, 2, \ldots \) in the series expansion in Eq. (113).

B.)

\[
\frac{d^2_f}{dS,dS} = \left\{ \frac{d^2_{MC}}{dS,dS} + \frac{1}{4} \sum_{l=1}^{\infty} \left( \frac{1}{2} \right)^{2l} a_{2l}(f) M_{2l}(S) \right\}. \quad (115)
\]

where the formal series expansion

\[
\hat{g}_f(x) = 1 + \sum_{l=1}^{\infty} a_{2l}(f)(x)^{2l}, \quad (116)
\]

defines the infinite sequence of coefficients \( a_{2l}(f), l = 1, 2, \ldots \) in the series expansion in Eq. (115).

**B. The integral presentation and the series expansions of \( d^2_f \)**

If one uses the detailing balancing equation (35), Eq. (107) may be recast in the form

\[
M_n(S) = \frac{1}{2} \int_{-\infty}^{\infty} \omega^n (1 - e^{-\omega}) Q_S(\omega) d\omega \quad n = 1, 3, 5, \ldots \quad (118)
\]

Thus, due to the fluctuation dissipation theorem (49) the following sum rule is valid

\[
M_n(S) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \chi''(\omega) \omega^n d\omega = \langle R_n(S)S \rangle_T, \quad n = 1, 2, 3, \ldots \quad (119)
\]

Plug the Eq. (119) in Eq. (113) one obtains the result

\[
\frac{d^2_f}{dS,dS} = \left\{ \frac{d^2_{BKM}}{dS,dS} + \frac{1}{8\pi} \sum_{l=1}^{\infty} \int_{-\infty}^{\infty} \left( \frac{1}{2} \right)^{2l-1} a_{2l-1}(f) \chi''(\omega) \omega^{2l-1} d\omega \right\}. \quad (120)
\]
Formally interchanging the integration and summation in the above expression and utilizing Eq. (114) in the form

$$
\sum_{l=1}^{\infty} a_{2l-1}(f) \left( \frac{\omega}{2} \right)^{2l-1} = \frac{2}{\omega} \left[ g_f \left( \frac{\omega}{2} \right) - 1 \right]
$$

(121)

we get back to Eq. (50). Thus we have two equivalent presentation of \( d_f^2 \) given by the series expansion Eq. (113) and by the integral presentation Eq. (50).

With similar algebra, one can show that \( d_f^2 \) given by Eq. (115) as a series expansion in terms of the even moments of DSF \( M_p(S) \), is equivalent to Eq. (50).

The alternative way to present \( d_f^2(S,S) \) with the help of the even moments of DSF, Eq. (115), is to start our consideration with the following (equivalent) presentation of Eq. (34)

$$
d_f^2(S,S) = \frac{1}{4} \left\{ \int_{-\infty}^{\infty} \hat{g}_f \left( \frac{\omega}{2} \right) Q_S(\omega) d\omega - \langle S \rangle^2 \right\}
$$

(122)

With a similar algebra as in the previous case one can show that \( d_f^2 \) given by Eq. (115) is equivalent to Eq. (50).

It is important to note that the key computational advantage of both formulas Eq. (113) (or Eq. (115)), instead of Eq. (34) (or Eq. (36)), is due to the existing presentation of functionals \( F_n(S;S) \) in Eq. (108) in terms of the iterated commutators Eqs. (111). Similarly to the terminology of Kubo for the admittance [49] these formulas may be called sum-rule expansions.

The presentations Eqs. (113) and (115) have an awkward feature: the summation is extended to infinity which raises the question about the convergence of the series. It is clear that the series representations should yield a proper definition of a monotone Riemannian metric provided the corresponding convergence condition is fulfilled. This point which in general is problematic due to the unknown behavior of the specters of the Hamiltonian \( T \) and operator \( S \) in functionals \( F_n(S;S) \) (or \( M_n(S) \)), \( n = 1, 2, \ldots \) needs special examination in the framework of concrete models.

VIII. APPLICATION TO MODELS

A.) We first illustrate the calculation of the whole class Riemannian metrics on the example of the simplest but instructive system of \( N \) spins in a constant magnetic field \( h \). The Hamiltonian of the model is

$$
H(h) = \omega_0 S_z + h S_z, \quad [S_x, S_y] = i S_z, \quad S_x^2 + S_y^2 + S_z^2 = S(S + 1),
$$

(123)

where \( S \geq 1/2 \) is the spin quantum number. In this case the dynamical structure factor with respect to \( S_x \) is (for more details see [29] and Section 7.4.4 [30])

$$
Q_{S_x}(\omega) = \frac{1}{2} \langle S_z \rangle_{H(0)} \delta(\omega - \omega_0) - \delta(\omega + \omega_0) (e^{\omega} - 1)^{-1}.
$$

(124)

After using the relation

$$
\langle S_z \rangle_{H(0)} = \frac{d}{dh} \ln Z(h) = (2S + 1) \coth \left( \frac{(2S + 1) h}{2} \right) - \coth \left( \frac{h}{2} \right) = 2SB_S(h/2),
$$

(125)

where \( B_S(h) \) is the Brillouin function, the application of Eq. (124) to Eq. (122) immediately yields the result

$$
d_f^2 = SB_S(h/2) \left( \frac{\omega_0}{2} \right)^{-1} g_f \left( \frac{\omega_0}{2} \right).
$$

(126)

B.) Let us consider the Hamiltonian [66, 67]:

$$
H(h) = k \omega \left( Q_k^0 - \frac{1}{k^2} \right) + h \sqrt{k^2} (Q_k^+ + Q_k^-), \quad k = 1, 2, \ldots,
$$

(127)

where \( Q_k^\pm \) are operators obeying the commutation relations

$$
[Q_k^0, Q_k^\pm] = \pm Q_k^\pm, \quad [Q_k^+, Q_k^-] = \Phi_k(Q_k^0) - \Phi_k(Q_k^0 - 1),
$$

(128)
with the structure function

\[ \Phi_k(Q_k^n) = -\Pi_{i=1}^k \left( Q_k^n + \frac{i}{k} - \frac{1}{k^2} \right) \]  

(129)

being a \(k^{th}\)-order polynomial in \(k\). The Hamiltonian \((127)\) is employed in various physical problems (for definitions and a partial list of references, see [66, 67]). Therefore, we shall derive closed expressions of the monotone Riemannian metrics within this class.

In this case our approach is very effective since the iterative commutation between \(T = k\omega (Q_k^L - \frac{1}{2})\) and \(S = \sqrt{k^2} (Q_k^+ + Q_k^-)\) implies some periodic operator structures after a finite number of steps as it was obtained in ref. [61]:

\[ R_n = (-1)^n R_n^+ = \alpha^n [Q_k^+ + (-1)^n Q_k^-], \quad (Q_k^-)^+ = Q_k^+, \]  

(130)

indicating an analytical expression as a function of \(n\). The parameters \(k\) and \(\omega\) enter in the c-number \(\alpha = (k\omega)^k \sqrt{k^{-n}}\).

Thus, the obtained series expansions Eqs. (113) and (115) can be used in a rather simple way to obtain closed-form expressions.

The polynomial algebra of degree \(k - 1\) defined by Eqs. (128) has the following one-mode boson realization [66]:

\[ Q_k^+ = \frac{1}{(\sqrt{k})^k} (b^+)^k, \quad Q_k^- = \frac{1}{(\sqrt{k})^k} b^k. \]  

(131)

In terms of Eqs. (131) the Hamiltonian of the model takes the more familiar form [67]

\[ \mathcal{H}(h) = \omega b^+ b + h[(b^+)^k + b^k], \quad \omega > 0, \quad k = 1, 2, 3, \ldots \]  

(132)

where bosonic operators \(b, b^+\) obey the canonical commutation relations.

The particular cases of \(k = 1\) and \(k = 2\) in Eq. (132) give the Hamiltonians of the displaced and single-mode squeezed harmonic oscillators, respectively. The Hamiltonian (132) for \(k = 2\) is also known as Lipkin-Meshkov-Glick (LMG) model in the Holstein-Primakoff single boson representation (see e.g. [12] and refs. therein) and all the result obtained here can be related to this field.

If \(p = 2n\), from (110) by using the expressions of \(R_0\) and \(R_{2n-1}\), we obtain

\[ F_{2n}(S; S) = -2(\omega)^{2n-1} \mathcal{K}(k), \quad n = 0, 1, 2, \ldots, \quad k = 1, 2, \ldots, \]  

(133)

where

\[ \mathcal{K}(k) = k^k \langle [Q_k^+] [Q_k^-+ Q_k^-] \rangle_T, \quad k = 1, 2, \ldots \]  

(134)

If \(p = 2n + 1\), from (110) by using the expressions of \(R_0\) and \(R_{2n}\), we obtain

\[ F_{2n+1}(S; S) = 2(\omega)^{2n} \mathcal{L}(k), \quad n = 0, 1, 2, \ldots, \quad k = 1, 2, \ldots, \]  

(135)

where

\[ \mathcal{L}(k) = k^k \langle [Q_k^+] [Q_k^-] \rangle_T, \quad k = 1, 2, \ldots \]  

(136)

Evaluation of the correlation functions Eqs. (134) and (136) with the quadratic Hamiltonian \(T\) is now straightforward. The results for \(k = 1\) and \(k = 2\) are:

\[ \mathcal{K}(1) = -1, \quad \mathcal{L}(1) = 2n + 1, \]

\[ \mathcal{K}(2) = -2(2n + 1), \quad \mathcal{L}(2) = 4n^2, \]  

(137)

where \(n = (e^\omega - 1)^{-1}\). Taking into account the relation (108) with the help of Eqs. (133) and (135), the series expansions – Eqs. (113) and (115) – may be recast in the closed form

\[ d_f^2 = d_{BKM}^2 + \frac{1}{4} \left( \frac{k\omega}{2} \right)^{-1} \left[ 1 - g_f \left( \frac{k\omega}{2} \right) \right] \mathcal{K}(k) \]  

(138)

and

\[ d_f^2 = d_{MC}^2 - \frac{1}{4} \left[ 1 - \hat{g}_f \left( \frac{k\omega}{2} \right) \right] \mathcal{L}(k), \]  

(139)

respectively.
IX. SUMMARY

The geometric approach traditionally plays an important role in deriving and elucidating theoretical results in various physical disciplines [69], especially for thermodynamics, see e.g. Ch. 7 in [30]. Recently, a number of papers [1, 3, 5, 10, 24] advocates an inherent relation between quantities from information geometry and statistical mechanics. The key point is that the monotone (contractive) Riemannian metrics (named also quantum Fisher informations) on the space of states can be identified and analyzed in terms of the behavior of the linear response functions, and vice-versa.

In the present study, the quantum states we are dealing with, may be realized as a set of one-parameter family of Gibbs thermal states, Eq. (6), obtained upon varying the Hamiltonian parameter “$h$” conjugated to an observable “$S$”. Our Eq. (60) relates the entire class of the monotone Riemannian metrics (or Fisher informations) $d_H^2(S, S')$ on the set of quantum states of the system under consideration, through the (filter [70]) function $g_f(x)$ to the dissipative component of the Kubo response function $\chi_{\omega}(\omega)$ in the state $\rho$ with respect to $S$. Since, a priori one can choose between many metrics, we discuss in Sec.V those of them which play an essential role from point of view of physics.

Practical applications of the general relations, i.e. Eqs. (50) for the integral presentation of $d_H^2(S, S)$, and (120) for the series expansion of $d_H^2(S, S)$ may occur in at least two aspects: to obtain estimates by some lower and upper bounds, and to apply the theory of perturbation.

A key point in our consideration is the use of the computational properties of the functionals Eq. (110) introduced previously in ref. [53]. These are presented in a basis independent form as thermodynamic mean values of n-times iterated (or nested) commutators, see Eq. (119), between $H(0)$ and $\partial_h H(h)$ which in some cases provides significant computational advantage [61]. The functionals, Eq. (110), are related to the moments of DSF [4] which play the role of the well known Kubo sum rules [49]. Estimations of hardly computable quantities from below and above, as a tool for obtaining exact results, are also widespread and traditional in information theory and statistical mechanics. A step in the right directions is the obtained inequalities between the different metrics obtained in Sections V and VI.

It should be stressed that the estimates, Eqs. (61), (68), (71) and the series of inequalities in Section VI are exact and cannot be inferred from any perturbation theory.

In order to position the obtained results among others in the field let us accent on the main source of deference. Note that in the definition of a metric, indeed, the essential is the scenario that renders two states, e.g. $\rho_1$ and $\rho_2$, distinguishable. One can see the difference if one compares the spectral presentation for MRM (the quantum Fisher informations) obtained through an unitary evolution $\rho(h) = e^{-ihS}\rho(0)e^{ihS}$ (relevant to a best achievable precision in the parameter estimating problem) with the spectral presentation obtained by infinitesimally variation of a control parameter “$h$” in the Hamiltonian that parameterized the Gibbs thermal states (relevant to quantum criticality). More technically, differences appear caused by the additional term $|E_n - E_m|^2$ (using our notations) in the denominator of the corresponding summand of the Bures metrics. This causes differences in the corresponding relations with the response functions (c.f. with ref. [33]).

Assuredly, links between families of metrics over the manifold of density matrices and response functions, obtained from different viewpoints, might cross-fertilize and extend both directions.

ACKNOWLEDGEMENTS

I would like to thank Valentin Zagrebnov for useful discussions and valuable comments. This work was supported by a Grant with the Joint Institute for Nuclear Research, Dubna, Russian Federation – THEME 01-3-1137-2019/2023 and Grant No D01-378/18.12.2020 of the Ministry of Education and Science of Bulgaria.

Appendix A: Operator Monotone Functions

Let us recall the definition of the operator monotone function. A real value function $f : (a, b) \to \mathbb{R}$, where $(a, b) \in \mathbb{R}$, is said to be monotone for finite-size $n \times n$ matrices $A \leq B$, whenever $A$ and $B$ are self-adjoint and their eigenvalues are in $(a, b)$, if $f(A) \leq f(B)$. If a function is monotone for every matrix size, then it is called operator monotone. By approximation arguments this definition is extend-able for operators on an infinite dimensional Hilbert space (for a more information about operator monotone functions, see e.g. [36, 71]).
Examples of the operator monotone functions $f \in \mathcal{F}_{op}$ are given in the list [23, 36, 38]:

\[
\begin{align*}
\mathcal{f}_{Har}(x) &= \frac{2x}{x+1}, \quad f_B(x) = \frac{x+1}{2}, \quad f_{BKM}(x) = \frac{x-1}{\ln x}, \\
\mathcal{f}_{MC}(x) &= \left(\frac{x-1}{\ln x}\right)^2 \frac{2}{1+x}, \quad f_G(x) = \sqrt{x}, \\
\mathcal{f}_{WYD}(\alpha, x) &= \alpha(\alpha-1)\frac{(x-1)^2}{(x^\alpha-1)(x^{1-\alpha}-1)}, \quad 0 < \alpha < 1.
\end{align*}
\] (A1)

In addition, we shall state a class of operator monotone functions which are an useful tool to illustrate ideas of this paper. The function $f_p(x)$

\[
f_p(x) = \frac{p-1}{p} \left( \frac{x^p - 1}{x^{p-1} - 1} \right)
\] (A2)

is an operator monotone function for $-1 \leq p \leq 2$. Note that a part of the above given examples of operator monotone functions, Eq. (A1), belongs to this class (see below) and in addition one can show that

\[
f_G(x) \leq f_p(x) \leq f_B, \quad \frac{1}{2} \leq p \leq 2.
\] (A3)

An operator monotone function $f : \mathbb{R}^+ \to \mathbb{R}^+$ is called symmetric if $f(x) : (0, +\infty) \to (0, +\infty); f(x^{-1}) = f(x)/x$ and normalized if $f(1) = 1$. It is commonly accepted to denote by $\mathcal{F}_{op}$ the set of the functions $f(x)$ characterized in this way. Some time these functions are called standard operator monotone functions as well [36]. The above examples of operator monotone functions have exactly these properties. The function $\mathcal{f}_{Har}(x)$ is the minimal, while $f_B(x)$ is the maximal operator monotone functions on $[0, +\infty)$. The former defines a metric known as RLD metric while the last one gives rise to the SLD metric (named also Bures metric or fidelity susceptibility). The function $f_{BKM}(x)$ leads to the Bogoliubov-Kubo-Mori metric. The function $f_{WYD}(\alpha, x)$ is associated to the Wigner-Yanase-Dyson metric. The function $f_{MC}(x)$ was first conjectured in the paper [22], which explains here the Wigner-Yanase-Dyson metric. Its matrix monontonicity was proved in [24].

In according with the Kubo and Ando theory of operator means (see, [35], Chapter V in ref. [36], [71]) to every operator mean corresponds a unique operator monotone functio $f \in \mathcal{F}_{op}$, and conversely. If $f \in \mathcal{F}_{op}$ then the corresponding mean is given by Eq. (3). The function Eq. (A2) is related with the so called power difference means, where the values $p = -1, 1/2, 1, 2$ correspond to the mentioned above operator monotone functions: $f_{-1}(x) \equiv f_{Har}(x)$ to harmonic mean, $f_{1/2}(x) \equiv f_G(x)$ to geometric mean, $f_1(x) = f_{BKM}(x)$ to logarithmic mean, and $f_2(x) = f_B(x)$ to arithmetic mean, respectively.
