Rapid method for determination of dehydro abietic acid in gum rosin and disproportionate rosin by proton nuclear magnetic resonance spectroscopy

Ravindra Kumar*, K. Chattopadhyay, Bantu Bhasker, Sujit Mondal, J. Christopher and G.S. Kapur

ABSTRACT
In present work a simple, direct and rapid method developed based on proton nuclear magnetic resonance spectroscopy for the quantitative determination of dehydroabietic acid in gum rosin and disproportionate rosins and validated. This method can also be applied to the determination of other acids of gum rosins like abietic acid, pimaric acid isopimaric acid, palustritic acid, neo abietic acid, levopimaric acid, tetrahydro abietic acid, dihydro abietic acid. Dehydroabietic acid has been estimated using aromatic proton while vinyl proton was used for estimation of other acids in gum rosins. Analysis of rosin acid methyl ester derivative in disproportionate rosins was also carried out by gas chromatography-mass spectroscopy to identify peak of dehydro abietic acid along with abietic acid based on their mass fragmentation pattern and quantified using gas chromatography with flame ionization detector. Good correlation was observed between the results of gas chromatography with flame ionization detector with newly developed nuclear magnetic resonance method.

KEYWORDS
Dehydro abietic acid, disproportionate rosin, nuclear magnetic resonance spectroscopy, gas chromatography-mass spectroscopy.

INTRODUCTION
Rosin acid is a raw material used in adhesives industry either as such or derivatives. Three sources of rosin are used for resin manufacture viz., gum rosin, wood rosin and tall oil rosin, all generated from the pine tree. Rosin acid unlike hydrocarbon resins, is not a polymer. It is a blend of distinct molecules. Rosin acid is a mixture of eight closely related rosin acids characterized by three fused six-carbon rings, double bonds that vary in number and location, and a single carboxylic acid group. The ratio of these isomers in rosin depends on the collection method and the species of the tree from which the rosin was harvested.

Gum rosin was once the only commercial source of rosin. It is the oleoresin (pine gum) of the living pine tree. The harvesting of the oleoresin is simple, involving only periodic wounding of the tree and collecting the sap into cups. Gum rosin contains abietic acid (AA) (Fig. 1a), dehydro abietic acid (DAA) (Fig. 1b), pimaric acid, isopimaric acid, palustritic acid, neo abietic acid, levopimaric acid, tetrahydro abietic acid and dihydro abietic acid. Major component of gum rosin is AA, which has a conjugated diene and is easily oxidizable. The stability of gum rosin increases by disproportionation reaction to produce disproportionate rosin (DPR) that is resistance to oxidation. Dehydro abietic acid (DAA) is the main component of DPR rosin, an important rosin derivative used industrially in paper sizing, coating compositions, synthetic resins and especially an emulsifying agent in the manufacturing of styrene butadiene rubber. There are several commercial grades of DPR rosins available in the market containing 30 to
65% DAA. Variation in disproportion processes causes considerable variation in DAA content as result of incomplete disproportion of the conjugated diene acids such as abietic, neoaibetic and palustic acids. This reduces the overall stability to oxidation and the usefulness of the end product, hence need for a method of DAA quantitation.

In the present work, a new analytical method based on proton nuclear magnetic resonance (\(^1\)H NMR) spectroscopy has been developed for the direct estimation of dehydroabietic acid in gum rosin and disproportionated rosins. This method can also be applied for the determination of other acids of gum rosins like Abietic acid (AA), pimaric acid, isopimaric acid, palustric acid, neo abietic acid, levopimaric acid, tetrahydro abietic acid, dihydro abietic acid. DAA has been estimated using aromatic proton and other acids have been estimated using unsaturated proton by quantitative NMR (qnmr). Gas chromatography-mass spectroscopy (GC-MS) analysis of methyl ester derivative of rosin acid and its DPR was carried out for detection of Dehydro Abietic acid (DAA) based on their mass fragmentation pattern (EI, 70 eV) and NIST library matching. However, their content in samples was estimated by gas chromatography with flam ionization detector (GC-FID). The outcome of NMR analysis was validated with GC results to check the appropriateness of the developed method, and good correlation was found.

**RESULTS AND DISCUSSION**

All gum rosins and DPR NMR spectra were recorded in acetone-d6 instead of Chloroform-d due to auto-oxidation of gum rosins in Chloroform-d. This auto oxidation of gum resins in chloroform starts after 30 minutes and the residual peak of chloroform at 7.26 ppm overlap with DAA peaks in 1H NMR spectrum of gum rosin and DPR; hence acetone-d6 is the best solvent for estimation of DAA.

The chemical shifts of the protons were more difficult to assign because of extensive overlap caused mainly by proton-proton coupling interactions. The assignments of 1H NMR spectrum of gum rosin and DPR have been assigned as per Landucci et al., 1991, which is given in Table 1. \(^1\)H NMR spectra of different origin gum rosins are given in Fig. 2 with their olefinic and aromatic regions and \(^1\)H NMR spectrum of DPR is given in Fig.3.
The vinyl protons of abietic acid (2) appeared at 5.76 ppm (1H, s) and at 5.35 ppm (1H, broad), levopimaric acid (3) appeared at 5.56 ppm (1H, s) and at 5.16 ppm (1H, broad), and only one vinyl proton in palustric acid (4) appeared at 5.38 ppm (1H, s). The protons of neoabietic acid (5) appeared at 6.21 ppm (1H, s) and Pimaric acid (6) at 4.95-4.84 (2H, m) and 5.84-5.71 (1H, m). For quantitative determination of the component acids present in the rosin acid, the respective areas of the vinyl proton signals were used throughout this work. Dehydroabietic acid which appeared at 7.34-6.87 ppm (3H) (1) and neoabietic acid (5) were able to be determined without being disturbed by the presence of other rosin acids. Abietic acid (2), levopimaric acid (3), palustric acid (4) and pimeric acid (6) were interfered by other rosin acid peaks which are also estimated using their characteristic peak integrations which is given in Table 1. Stacked 1H NMR spectra of reactant (Gum rosin) and treated rosin (DPR) has been given in Fig. 4.

| S. No | Rosin Acids          | Chemical Shift used for quantification (ppm) | No of Protons |
|-------|----------------------|---------------------------------------------|---------------|
| 1     | Dehydroabietic acid  | 7.34-6.87 (I\textsubscript{DA})              | 3H            |
| 2     | Abietic acid         | 5.76 (I\textsubscript{A})                   | 1H            |
| 3     | Levopimaric acid     | 5.16 (I\textsubscript{L})                   | 1H            |
| 4     | Palustric acid       | 5.38 (I\textsubscript{P})                   | 1H            |
| 5     | Neoabietic acid      | 6.21 (I\textsubscript{N})                   | 1H            |
| 6     | Pimeric acid         | 4.95-4.84 (I\textsubscript{PM})              | 2H            |
|       |                      | 5.84-5.71 (I\textsubscript{pm})              |               |

Table 1 Characteristic peaks of different type rosin acids

Fig. 2 $^1$H NMR spectra of different origin Gum rosins
DAA has been estimated using aromatic proton and other acids have been estimated using vinyl proton. Three aromatic protons integration of DAA has been used for quantitative estimation of DAA. The amount (%) of DAA ($W_{DA}$) has been estimated by quantitative $^1$H NMR experimentation while compared with known amount of HMDSO ($W_{HMDSO}$). The following equations have been used for the estimation.

$$W_{DA} = \frac{(W_{HMDSO} * M_{DA} * N_{HMDSO} * I_{DA})}{(M_{HMDSO} * N_{DA} * I_{HMDSO})}$$

$$W_{DA} = 0.11085 \frac{(W_{HMDSO} * M_{DA} * I_{DA})}{(N_{DA} * I_{HMDSO})} \quad (1)$$

Where, $W_{DA}$ = Weight of component to be estimated, $W_{HMDSO}$ = Weight of HMDSO taken, $M_{DA}$ = Molecular weight of component, $I_{DA}$ = Integral value of the relevant chemical shift region of the component, $N_{DA}$ = Number of protons in the chemical shift region with integral $I_{DA}$, $I_{HMDSO}$ = Integration value for HMDSO at 0.07, $N_{HMDSO}$ = 18 and $M_{HMDSO}$ = 162.38.

An analogous equation has been used to estimate other acids and given as follows:

$$W_x = \frac{(W_{HMDSO} * M_x * N_{HMDSO} * I_x)}{(M_{HMDSO} * N_x * I_{HMDSO})}$$

$$W_x = 0.11085 \frac{(W_{HMDSO} * M_x * I_x)}{(N_x * I_{HMDSO})} \quad (2)$$

Where, $W_x$ = Weight of acid to be estimated, $W_{HMDSO}$ = Weight of HMDSO taken, $M_x$ = Molecular weight of acid, $I_x$ = Integral value of the relevant chemical shift region of the acid as given in Table 1, $N_x$ = Number of protons in the chemical shift region with integral $I_x$ as given in Table 1, $I_{HMDSO}$ = Integration value for HMDSO at 0.07, $N_{HMDSO}$ = 18 and $M_{HMDSO}$ = 162.38.
Characteristics peak of abietic acid at 5.76 ppm overlapped with pimeric acid one proton (Ipm), so IA has been estimated as per eq. 3.

\[ I_A = I_{pm} - I_{pm}/2 \] ------ (3)

DAA estimated in DPR of different origin gum rosins by 1H NMR is, given in Table II. Analysis of rosin acid methyl ester derivative in DPR was carried out in GC-MS to identify peak of Dehydro Abietic acid (DAA) along with Abietic acid (AA) based on their mass fragmentation pattern (EI, 70 eV). The peak eluting at 22.185 minutes was compared to Dehydroabeitic acid (DAA) and unambiguously confirmed by NIST library matching. Dehydroabeitic and Abietic acid were quantified in DPR treated rosin acids using GC-FID (Fig. 5) and results were compared with newly developed NMR method (Table 2). A good correlation was observed between NMR and GC results for DAA in DPR. Other rosin acids have also been estimated in different origins DPR by 1H NMR spectroscopy, which is given in Table 3.

After the synthesis of DPR from gum rosins, it has been observed that, 75-80% of abeitic acid, neoabeitic acid and palusteric acid were converted in DAA while 40-45% of pimeric acid and isopemeric acids were converted in DAA. It is important to mention here that isomerization of levopimaric acid and neoabietic acid into abeitic acid followed by auto-oxidation to DAA was observed in Chloroform–d after a certain time (6 hours). Several investigations have been made for the transformations of individual component resin acids during rosin disproportionate (Fleck and Palkin 1937; Fleck and Palkin1938; Mostafalu et al., 2017)

**CONCLUSION**

A simple, direct and rapid 1H NMR method for the quantitative determination of dehydrobiabetic acid in gum rosin and disproportionated rosins was developed and validated. This NMR method has also applied for the determination of other acids of gum rosins like Abietic acid (AA), pimaric acid isopimaric acid, palustric acid, neo abietic acid, levopimaric acid, tetrahydro abietic acid and dihydro abietic acid.

**MATERIAL AND METHODS**

**Sample**

Gum resins from China and India origin and their DPR have been used for this study.

**Synthesis of DPR**

Disproportionate reaction of gum rosin was carried out by using Palladium charcoal catalyst. In Disproportionation experiment, 100g of gum rosin was heated under nitrogen (hot plate) in a 250 ml of glass bottle equipped with magnetic stirrer and thermometer. The 5% Pd on charcoal catalyst (290 mg) was added when temperature reached to 230°C and then the reaction temperature was slowly increased to 270°C. The mixture was heated at 270°C for 6 hours. The reaction mixture was cooled to RT and then the solid was dissolved in dichloromethane and filtered. The final product, DPR was obtained after removal of the solvent.

**Sample Preparation**

The sample of gum rosin and DPR (40 to 60 mg) were weighed into a NMR tube with its cap fitted at the top and allowed it to reach equilibrium. The standard reference compound (5 to 15 mg) was then added and recorded the amount up to 5 digits for both the cases. The sample was then diluted with CDCl₃ (~0.7 mL) and recorded the spectra.

A highly sensitive balance (Sartorius BP 211D, Gottingen, Germany) was used to weigh the sample and standard (upto 5-decimal). The methyl peak of HMDSO was used as a frequency reference and set to 0.07 ppm downfield from TMS.

**Selection of a Suitable Reference Compound for Quantitative NMR Spectroscopy**

For quantitative 1H NMR spectroscopy, hexamethyldisiloxane (HMDSO) has been selected as an excellent internal reference standard which meets all the desirable characteristics. Purity of HMDSO used has also been thoroughly checked. It has been found that increasing the relaxation delay from 5s to 20s does significantly influences the integral value and so most of the samples were recorded with 20s relaxation delay.

**NMR Method**

All proton NMR spectra were recorded on a Jeol ECA-500 NMR spectrometer operating at the proton frequency of 500 MHz, spectral width 7512 Hz (-2.5-12.5 ppm), 90° pulse = 10.7 µs, relaxation delay = 20s, digital resolution 0.49 Hz/point. 32 repetitions were averaged with 32K data point and 6.38 minutes experimental time. All the NMR spectra were integrated after baseline correction, and a mean of minimum three integration values has been taken for each calculation.

**GC and GC-MS**

The conversion of acids present in the gum rosin samples to methyl ester was carried out by N,N-Dimethylformamide Dimethyl Acetal (DMF-DMA) reagent as per the ASTM D 5975 method. 0.5 gm rosin acid was taken in an appropriate anhydrous vial and dissolved in approximately 0.5 mL of toluene. Then
approximately 1 mL of DMF-DMA was added to the mixture and maintained at 50°C for 120 minutes. Finally, the resultants were used for GC analysis.

The qualitative analysis was carried out on using Bruker GC-MS (Scion SQ, 436-GC) with the help of a polar column; (RTX-2330; 60m x 0.32 mm ID x 0.2 µm) procured from M/s Restek to identify the compound. However, quantification of DPR was achieved using PerkinElmer Clarus 500 GC instrument equipped with FID and split/split less injector. The following analytical conditions were used during analysis in GC-FID and GC-MS respectively.

**Parameters of GC-FID**
- Split ratio: 10:1
- Oven programme: 150 °C (5 minutes hold) - 3°C/ minute -250°C (15 minutes hold)
- Injector and Detector temperature: 300 and 320 °C respectively
- Carrier (Helium) gas Flow: 1.5 ml/min
- Sample injection volume: 0.2 µl.

**Parameters of GC-MS**
- Operating Mode: Scan mode with 10:0 split
- Carrier Flow: 1 ml/min column flow for GC-MS
- Oven programme: 150 °C (5 minutes hold) - 3°C/ minute -250°C (15 minutes hold) 250°C (10 minutes hold)
- Injector temperature: 300 °C
- MS Source and transfer line: 230 and 250 °C respectively
- Ionization: El (70 eV)
- Scan Range: m/z 40 - 500
- Injection Volume: 0.4 µl.
