FAMILIES OF GRAPHS WITH TWIN PENDENT PATHS AND THE BRAESS EDGE

SOOYEONG KIM

Abstract. In the context of a random walk on an undirected graph, Kemeny’s constant can measure the average travel time for a random walk between two randomly chosen vertices. We are interested in graphs that behave counter-intuitively in regard to Kemeny’s constant: in particular, we examine graphs with a cut-vertex at which at least two branches are paths, regarding whether the insertion of a particular edge into a graph results in an increase of Kemeny’s constant. We provide several tools for identifying such an edge in a family of graphs and for analysing asymptotic behaviour of the family regarding the tendency to have that edge; and classes of particular graphs are given as examples. Furthermore, asymptotic behaviours of families of trees are described.

Key words. Kemeny’s constant, Random walk on a graph, Braess edge.

AMS subject classifications. 05C50, 05C81.

1. Introduction. Imagine a situation that adding roads to a road network in order to reduce traffic congestion results in, on contrary to one’s expectation, slowing down overall traffic flow (called Braess’s paradox [3]). Random walks on graphs can also exhibit a version of this paradox. The family of random walks on undirected graphs is a special type of Markov chain: the transition probability from an initial state to another is given by the inverse of the degree of the vertex corresponding to the initial state. The parameter known as Kemeny’s constant can be used to measure the average time for travel of a Markov chain between two randomly chosen states; so, in the context of random walks, it can be interpreted as a measure of how well connected the vertices of a graph are. Related applications can be found in [18] for detecting potential super-spreaders of COVID-19, and in [9] for determining ‘critical’ roads in vehicle traffic networks based on Markov chains.

Kemeny’s constant can serve as a proxy for identifying an edge exhibiting the version of the paradox [13], by examining an edge whose insertion into an undirected graph corresponding to a road network increases Kemeny’s constant for random walks on the graph (such an edge is called a Braess edge) that corresponds to travel times on the network. In the present paper, we study under what circumstances graphs can have a Braess edge in order to see what type of graphs exhibit the version of the paradox.

The term ‘Braess edge’ is introduced in [13] and acknowledges Dietrich Braess who studies Braess’s paradox for traffic networks [3]. Kirkland and Zeng [13] provides a particular family of trees, with a vertex adjacent to two pendent vertices (such two vertices are called twin pendent vertices), such that inserting an edge between the twin pendent vertices causes Kemeny’s constant to increase. Furthermore, Ciardo [8] extends the result to all connected graphs with twin pendent vertices. Unlike the works [13] and [8], Hu and Kirkland [11] establishes equivalent conditions for complete multipartite graphs and complete split graphs to have every non-edge as a Braess edge.
Our work is to generalise the circumstances in [8, 13] where graphs have a pair of twin pendent vertices; so, we consider graphs that can be constructed from a connected graph and two paths by identifying a vertex of the graph and a pendent vertex of each path. We call the two paths twin pendent paths in the constructed graph. In Section 3, a formula is derived that identifies a graph with twin pendent paths in which the non-edge between the pendent vertices of the twin pendent paths is a Braess edge. In Section 4, a combinatorial expression is provided in order to investigate asymptotic behaviour of a family of graphs with twin pendent paths regarding the tendency to have the non-edge, between the pendent vertices of the twin pendent paths, as a Braess edge. Furthermore, several families of graphs are discussed throughout Sections 3, 4 and 5. In particular, asymptotic behaviours of families of trees are characterised in Section 5.

2. Preliminaries. Throughout the paper, we assume all graphs to be simple and undirected.

We shall introduce necessary terminology and notation in graph theory. Let \( G \) be a graph of order \( n \) with vertex set \( V(G) \) and edge set \( E(G) \) where \( n = |V(G)| \). An edge joining vertices \( v \) and \( w \) of \( G \) is denoted by \( v \sim w \). Let \( m_G \) be defined as \( |E(G)| \). The subgraph of \( G \) induced by a subset \( S \) of \( V(G) \) is the graph with vertex set \( S \), where two vertices in \( S \) are adjacent if and only if they are adjacent in \( G \). For \( v \in V(G) \), we denote by \( \deg_G(v) \) the degree of \( v \). A vertex \( v \) of a graph \( G \) is said to be pendent if \( \deg_G(v) = 1 \). Given a labelling of \( V(G) \), we define \( d_v \) to be the column vector whose \( i \)th component is \( \deg_G(v_i) \) for \( 1 \leq i \leq n \), where \( v_i \) is the \( i \)th vertex in \( V(G) \). For \( v, w \in V(G) \), the distance between \( v \) and \( w \) in \( G \) is denoted by \( \text{dist}_G(v, w) \). For a connected graph \( G \) with a vertex \( v \), the eccentricity \( e_G(v) \) of \( v \) in \( G \) is \( e_G(v) = \max\{\text{dist}_G(v, w) | w \in V(G)\} \). The diameter, denoted \( \text{diam}(G) \), of \( G \) is \( \text{diam}(G) = \max\{e_G(v) | v \in V(G)\} \).

The trivial graph is the graph of order 1. A tree is a connected graph that has no cycles. A forest is a graph whose connected components are trees. A spanning tree (resp. a spanning forest) of \( G \) is a subgraph that is a tree (resp. a forest) and includes all of the vertices of \( G \). A k-tree spanning forest of \( G \) is a spanning forest that consists of \( k \) trees. For \( v \in V(G) \), we use \( G - v \) to denote the graph obtained from \( G \) by the deletion of \( v \). A vertex \( v \) of a connected graph \( G \) is called a cut-vertex of \( G \) if \( G - v \) is disconnected. If \( G - v \) has \( k \) connected components \( G_1, \ldots, G_k \) for some \( k \geq 2 \), then the subgraph induced by \( V(G_i) \cup \{v\} \) for \( 1 \leq i \leq k \) is called a branch of \( G \) at \( v \).

Let us introduce several types of connected graphs. We denote the complete graph of order \( n \) by \( K_n \), the cycle of length \( n \) by \( C_n \), and the path on \( n \) vertices by \( P_n \). If we need to specify the ordering of vertices of a cycle or a path, then we use \( C_n = (v_1, v_2, \ldots, v_n, v_1) \) to denote the cycle whose vertices are labelled by \( v_1, \ldots, v_n \), and whose edges are \( v_1 \sim v_n \) and \( v_i \sim v_{i+1} \) for \( i = 1, \ldots, n-1 \); similarly, \( P_n = (v_1, v_2, \ldots, v_n) \) denotes the path whose vertices are labelled by \( v_1, \ldots, v_n \) and whose edges are \( v_i \sim v_{i+1} \) for \( i = 1, \ldots, n-1 \). A star \( S_n \) is a tree on \( n \) vertices with one vertex of degree \( n - 1 \). For \( n \geq 3 \), \( v \) is called the centre vertex of \( S_n \) if \( \deg_{S_n}(v) = n - 1 \). For \( n > k \geq 1 \), a broom \( B_{n,k} \) is a tree constructed from the path on \( k \) vertices by adding \( n - k \) pendent vertices to one pendent vertex on the path.

Let \( k \geq 2 \), and let \( G_i \) be a graph with \( v_i \in V(G_i) \) for \( i = 1, \ldots, k \). Suppose that \( V(G_1), \ldots, V(G_k) \) are disjoint. Let \( v \notin V(G_i) \) for \( i = 1, \ldots, k \). We consider a graph \( G \) with vertex set \( V(G) = \{v\} \cup \left( \bigcup_{i=1}^{k} (V(G_i) - v_i) \right) \), where two vertices \( x \) and \( y \) in \( G \) are adjacent if and only if it satisfies one of the following: (i) \( x \sim y \in \bigcup_{i=1}^{k} E(G_i) \); and (ii) one of \( x \) and \( y \) is \( v \), and the other is a vertex adjacent to \( v_j \) in \( G_j \) for some \( 1 \leq j \leq k \). Then, we say that the graph \( G \) is obtained from \( G_1, \ldots, G_k \) by identifying vertices \( v_1, \ldots, v_k \) as \( v \).
Families of graphs with twin pendent paths and the Braess edge

Let $G$ be a graph. Let $P_{k_1+1} = (v_1, \ldots, v_{k_1}+1)$ and $P_{k_2+1} = (w_1, \ldots, w_{k_2}+1)$ where $k_1$ and $k_2$ are non-negative integers with $k_1 + k_2 \geq 2$. Suppose that $\tilde{G}$ is the graph obtained from $G$, $P_{k_1+1}$, and $P_{k_2+1}$ by identifying a vertex $v$ of $G$, $v_1$, and $w_1$ as $v$. We say that the paths $(v, v_2, \ldots, v_{k_1}+1)$ and $(v, w_2, \ldots, w_{k_2}+1)$ in $\tilde{G}$ are twin pendent paths (see Figure 1 for illustration). Then, the pendent vertices of the twin pendent paths in $\tilde{G}$ are $v_{k_1}+1$ and $w_{k_2}+1$. We remark that considering the construction of $\tilde{G}$, it is reasonable to assume that $k_1$ and $k_2$ are permitted to be 0 (we consider it throughout this paper), as opposed to one’s anticipation from the word ‘twin pendent paths’, in that $P_{k_1+1}$ and $P_{k_2+1}$ both are of length at least 1.

Consider a discrete, finite, time-homogeneous Markov chain whose finite state space is $\{1, \ldots, n\}$. The Markov chain can be represented by the transition matrix $M$. (We refer the interested reader to [17] for the necessary background for Markov chains.) Then, Kemeny’s constant $\kappa(M)$ is defined as $\sum_{j\neq i}^n m_{i,j}w_j$, where $m_{i,j}$ is the mean first passage time from state $i$ to state $j$, and $w_j$ is the $j$th entry of the stationary distribution. Note that Kemeny’s constant is independent of $i$. It is found in [16] that $\kappa(M) + 1 = \sum_{i=1}^n \sum_{j=1}^n w_i m_{i,j} w_j$. This admits the interpretation of Kemeny’s constant in terms of the expected number of steps from a randomly chosen initial state to a randomly chosen final state. Alternatively, $\kappa(M)$ can be expressed as $\kappa(M) = \sum_{j=2}^n \frac{1}{1-\lambda_j}$ where $1, \lambda_2, \ldots, \lambda_n$ are the eigenvalues of $M$. For the details, the reader may refer to [12].

For our work, we use the combinatorial expression for Kemeny’s constant for a random walk on a connected graph in [13]. In order to emphasise that we are dealing with random walks on connected graphs, given a connected graph $G$, we use $\kappa(G)$ to denote Kemeny’s constant for the transition matrix of the random walk on $G$. We denote by $\tau_G$ the number of spanning trees of $G$, and by $\mathcal{F}_G(i;j)$ the set of 2-tree spanning forests of $G$ such that one of the two trees contains a vertex $i$ of $G$, and the other has a vertex $j$ of $G$. We define $F_G$ to be the matrix given by $F_G = [f_{i,j}^G]$ where $f_{i,j}^G = |\mathcal{F}_G(i;j)|$. Note that $f_{i,i}^G = 0$, that is, the diagonal entries of $F_G$ are zero. Recall that $m_G$ is the number of edges of $G$. Then, Kemeny’s constant for the transition matrix of the random walk on $G$ is given by:

$$\kappa(G) = \frac{d_G^T F_G d_G}{4m_G^2}.$$

A non-edge $e$ of $G$ is said to be a Braess edge for $G$ if $\kappa(G) < \kappa(G \cup e)$ where $G \cup e$ is the graph obtained from $G$ by adding $e$ to $G$. A connected graph $G$ is said to be paradoxical [8] if there exists a Braess edge for $G$.

We also introduce some useful notation. We denote by $1_k$ the all 1’s vector of size $k$, by $0_k$ the all 0’s vector of size $k$, and by $J_{p,q}$ the all 1’s matrix of size $p \times q$. If $k = p = q$, we write $J_{k}$ as $J_k$. The subscripts
$k$ and a pair of $p$ and $q$ are omitted if their sizes are clear from the context. We denote by $e_v$ the column vector whose component in $v^{th}$ position is 1 and 0’s elsewhere, and denote by $f_G^i$ the $i^{th}$ column of $F_G$. Then, the $i^{th}$ entry of $f_G^i$ is $f_{i,v}$. Moreover, $f_G^i$ can be written as $f^i$ if $G$ is clear from the context.

We assume familiarity with basic material on graph theory. We refer the reader to [6] for the necessary background. In what follows, we omit $G$ that is a subscript or a superscript in the notation described in this section when no confusion arises, and we use boldface lowercase letters to denote column vectors.

3. Graphs with twin pendent paths and the Braess edge. In this section, for a connected graph with twin pendent paths, we provide an equivalent condition for the non-edge between the pendant vertices of the twin pendent paths to be a Braess edge. Moreover, we examine several families of graphs through the equivalent condition.

We begin with investigating the components in the expression for Kemeny’s constant $\kappa(G)$ where $G$ is a connected graph with a cut-vertex—a connected graph with twin pendent paths has a cut-vertex.

**Proposition 3.1.** Let $H_1$ and $H_2$ be connected graphs, and let $v_1 \in V(H_1)$ and $v_2 \in V(H_2)$. Assume that $G$ is obtained from $H_1$ and $H_2$ by identifying $v_1$ and $v_2$ as a vertex $v$. Suppose that $H_1 = H_1 - v_1$ and $H_2 = H_2 - v_2$. Then, labelling the vertices of $G$ in order of $V(H_1)$, $v$ and $V(H_2)$, we have

$$d_G^T = [d_{H_1}^T, 0_{|V(H_2)|}^T] + [0_{|V(H_1)|}^T, d_{H_2}^T],$$

$$m_G = m_{H_1} + m_{H_2},$$

$$\tau_G = \tau_{H_1} \tau_{H_2},$$

$$F_G = \begin{bmatrix} \tau_{H_1} f_{H_1} & \tau_{H_2} f_{H_2} & \tau_{H_1} f_{H_1}^T + \tau_{H_1} f_{H_1}^T \\ \tau_{H_2} f_{H_1} & 0 & \tau_{H_1} f_{H_1}^T \\ \tau_{H_2} f_{H_1}^T + \tau_{H_2} f_{H_2} & \tau_{H_2} f_{H_2} & \tau_{H_2} f_{H_2}^T \end{bmatrix},$$

where $f_1$ and $f_2$ are the column vectors obtained from $f_{H_1}$ and $f_{H_2}$ by deleting the $v^{th}$ component (which is 0), respectively. Furthermore, we obtain

$$d_G^T F_G d_G = \tau_{H_1} d_{H_1}^T F_{H_1} d_{H_1} + \tau_{H_2} d_{H_2}^T F_{H_2} d_{H_2} + 4 \tau_{H_1} m_{H_1} d_{H_1}^T f_{H_1}^T + 4 \tau_{H_2} m_{H_2} d_{H_2}^T f_{H_2}^T.$$

**Proof.** The conclusions for $d_G$ and $m_G$ are readily established. We shall consider $F_G$ and $\tau_G$. Since $f_{ij}^G = f_{ij}^H$ for all $i,j \in V(G)$, $F_G$ is symmetric. Hence, we only need to verify the entries above the main diagonal. Note that $v$ is a cut-vertex of $G$. Since all spanning trees of $G$ can be obtained from spanning trees of $H_1$ and of $H_2$ by identifying $v_1$ and $v_2$ as $v$, we have $\tau_G = \tau_{H_1} \tau_{H_2}$. Let $i,j \in V(H_1)$. For each spanning forest of $H_1$ in $F_{H_1}(i,j)$, we can obtain $\tau_{H_2}$ spanning forests of $G$ in $F_G(i,j)$ from the forest of $H_1$ and each of $\tau_{H_2}$ spanning trees of $H_2$ by identifying $v_1$ and $v_2$. Therefore, $f_{ij}^G = \tau_{H_2} f_{ij}^H$ for $i,j \in V(H_1)$. Similarly, for $i,j \in V(H_2)$, we have $f_{ij}^G = \tau_{H_1} f_{ij}^H$. Let $i \in V(H_1)$ and $j \in V(H_2)$. The set $F_G(i,j)$ is a disjoint union of $A_i$ and $A_j$, where $A_i$ is the set of spanning forest of $G$ in $F_G(i,j)$ such that the tree having the vertex $i$ among the two trees contains $v$, and $A_j = F_G(i,j) \cap A_i$. Since for each spanning forest in $A_i$ the tree with $i$ has $v$, the tree contains a spanning tree of $H_1$ as a subtree. So, any forest in $A_i$ can be constructed from a spanning tree of $H_1$ and a spanning forest in $F_{H_2}(v_2;j)$ with $v_1$ and $v_2$ identified as $v$. Hence, we have $|A_i| = \tau_{H_1} f_{v_2;j}^H$. Note that $f_{v_1,v_1}^{H_1} = f_{v_1,v_1}^{H_2}$. Applying an analogous argument to the case $|A_j|$, we have $|A_j| = \tau_{H_2} f_{v_2;j}^H$. Thus, $f_{ij}^G = \tau_{H_2} f_{i,v_1} + \tau_{H_1} f_{v_2;j}$ for $i \in V(H_1)$ and $j \in V(H_2)$. Therefore, our desired results for $F_G$ and $\tau_G$ are obtained.
Families of graphs with twin pendent paths and the Braess edge

Now, we shall prove (3.2). Labelling the vertices of $H_1$ (resp. $H_2$) in order of $V(H_1)$ and $v$ (resp. $v$ and $V(H_2)$), we have

$$\tau_{H_2}F_{H_1} = \begin{bmatrix} \tau_{H_2}F_{H_2} & \tau_{H_2}f_1 \\ \tau_{H_2}f_1^T & 0 \end{bmatrix}, \quad \tau_{H_1}F_{H_2} = \begin{bmatrix} 0 & \tau_{H_1}f_1^T \\ \tau_{H_1}f_2 & \tau_{H_1}F_{H_2} \end{bmatrix}.$$  

Note that $(f_{H_2}^T)^T = [f_1^T 0]$ and $(f_{H_2}^T)^T = [0 f_2^T]$.

Then, we have

$$\begin{bmatrix} \tau_{H_2}f_1 & \tau_{H_2}f_11^T_{V(H_2)} + \tau_{H_1}1_{V(H_1)}f_2^T \\ 0 & \tau_{H_1}f_2^T \end{bmatrix} = \tau_{H_2}f_{H_1}^T1^T_{V(H_2)} + \tau_{H_1}1_{V(H_1)}(f_{H_2}^T)^T.$$  

Considering $d_G^T = [d_{H_1}^T, 0^T_{|V(H_2)|}] + [0^T_{|V(H_1)|}, d_{H_2}^T]$ with $F_G$ in (3.1), we have

$$d_G^TF_Gd_G = \tau_{H_2}d_{H_1}^TF_{H_1}d_{H_1} + \tau_{H_1}d_{H_2}^TF_{H_2}d_{H_2} + 2d_{H_1}^T\begin{bmatrix} \tau_{H_2}f_1 & \tau_{H_2}f_11^T + \tau_{H_1}f_2^T \\ 0 & \tau_{H_1}f_2^T \end{bmatrix}d_{H_2}$$

$$= \tau_{H_2}d_{H_1}^TF_{H_1}d_{H_1} + \tau_{H_1}d_{H_2}^TF_{H_2}d_{H_2} + 2d_{H_1}^T\left(\tau_{H_2}f_{H_1}^T1^T_{V(H_2)} + \tau_{H_1}1_{V(H_1)}(f_{H_2}^T)^T\right)d_{H_2}$$

$$= \tau_{H_2}d_{H_1}^TF_{H_1}d_{H_1} + \tau_{H_1}d_{H_2}^TF_{H_2}d_{H_2} + 4\tau_{H_2}m_{H_2}d_{H_1}^Tf_{H_1}^T + 4\tau_{H_1}m_{H_1}d_{H_2}^Tf_{H_2}^T.$$

We can see from Proposition 3.1 that given $m_{H_1}$ and $\tau_{H_1}$ for $i = 1, 2$, $d_G^TF_Gd_G$ can be computed from $d_{H_1}^TF_{H_1}d_{H_1}$ and $d_{H_2}^TF_{H_2}d_{H_2}$ for $i = 1, 2$. The following examples regarding $K_n$, $C_n$, $P_n$ and $S_n$ present the corresponding quantities $d^T F d$ and $d^T f^v$ and assist us later to obtain several results and related examples.

**Example 3.2.** Consider a complete graph $K_n$ on $n$ vertices. Then, $m = \binom{n}{2}$ and $\tau = n^{n-2}$ by Cayley’s formula (see [6]). Note that $K_n$ is symmetric (see [10]), that is, for any pair of edges of $K_n$, there is an automorphism that maps one edge to the other. So, $F_{K_n} = \alpha(J - I)$ where $\alpha = f_{i,j}^{K_n}$ for all $i, j \in V(K_n)$. Then, $\alpha$ is the determinant of the submatrix obtained from the Laplacian matrix of $K_n$ by deleting $i$th and $j$th rows and columns where $i \neq j$ (see [5]). It can be seen that $\alpha = 2n^{n-3}$. Therefore, for any vertex $v$ in $K_n$, we have

$$d^T F d = \alpha(n - 1)^21^T(J - I)1 = 2n^{n-2}(n - 1)^3,$$

$$d^T f^v = \alpha(n - 1)1^T(1 - e_v) = 2n^{n-3}(n - 1)^2.$$  

**Example 3.3.** Consider the cycle $C_n = (1, 2, \ldots, n, 1)$ where $n \geq 3$. For $1 \leq v \leq n$, we obtain

$$F_{C_n} = \begin{bmatrix} \text{dist}(i, j)(n - \text{dist}(i, j)) \end{bmatrix}_{1 \leq i, j \leq n}, \quad d = 21,$$

$$(f^v)^T = [(v - 1)(n - v)) \cdots 1 \cdot (n - 1) \cdots (n - v)^n].$$

It can be checked that for $v = 1, \ldots, n$,

$$d^T F d = \frac{2}{3}(n - 1)n^2(n + 1)$$

and

$$d^T f^v = \frac{1}{3}(n - 1)n(n + 1).$$

Note that for any tree $T$, $F_T$ is the distance matrix of $T$ (see [13]), which is the matrix whose $(i, j)$-entry is the distance between $i$ and $j$. 

One can verify that for $\kappa$ we need to investigate that we have $R$.

Let us continue with the hypothesis and notation of Definition 3.6. To see if we obtain from $\hat{G}$, we shall find an equivalent condition for $\tilde{T}$.

Example 3.4. Consider the path $P_n = (1, 2, \ldots, n)$ where $n \geq 2$. Let $v$ be a vertex of $P_n$. For $1 \leq v \leq n$, we have

$$F_{P_n} = [i - j]_{1 \leq i, j \leq n} \cdot d = 21_n - e_1 - e_n,$$

$$d^T F d = 41^T F 1 - 41^T F e_1 - 41^T F e_n + 2e_1^T F e_n = \frac{4}{3}(n - 1)^3 + \frac{2}{3}(n - 1),$$

$$d^T f^v = (v - 1)^2 + (n - v)^2.$$ 

Example 3.5. Consider a star $S_n$ of order $n$ where $n \geq 3$. Suppose that $n$ is the centre vertex. Then, we have

$$d^T = [1_{n-1}^T 0] + (n - 1)e_n, \quad F_{S_n} = \begin{bmatrix} 2(J - I) & 1_{n-1}^T \\ 1_{n-1} & 0 \end{bmatrix}.$$ 

Hence, we have that for $v = 1, \ldots, n$,

$$d^T F d = 21_{n-1}^T (J - I) 1_{n-1} + 2(n - 1)^2 = 2(n - 1)(2n - 3),$$

$$d^T f^v = \begin{cases} n - 1, & \text{if } v = n \\ 3n - 5, & \text{if } v \neq n. \end{cases}$$ 

We consider the following definition for clarity of exposition regarding our work in this paper.

Definition 3.6. Let $G$ be a connected graph on $n$ vertices, and $v \in V(G)$. Fix two non-negative integers $k_1, k_2$ with $k_1 + k_2 \geq 2$. Let $\hat{G}(v, k_1, k_2)$ denote the graph obtained from $G$, $P_{k_1+1} = (v_1, \ldots, v_{k_1+1})$ and $P_{k_2+1} = (w_1, \ldots, w_{k_2+1})$ by identifying the vertices $v, v_1$ and $w_1$. Also, we denote by $\tilde{G}(v, k_1, k_2)$ the graph obtained from $\hat{G}(v, k_1, k_2)$ by inserting the edge $v_{k_1+1} \sim w_{k_2+1}$. We say that $G$ is $(v, k_1, k_2)$-paradoxical if $\kappa(\hat{G}(v, k_1, k_2)) > \kappa(\tilde{G}(v, k_1, k_2))$. If $G$ is $(v, k_1, k_2)$-paradoxical for every $v \in V(G)$, then we say that $G$ is $(k_1, k_2)$-paradoxical.

Our main goal stated in the beginning of this section can be rephrased in terms of Definition 3.6: given a connected graph $G$ with a vertex $v$, we shall find an equivalent condition for $G$ to be $(v, k_1, k_2)$-paradoxical.

Example 3.7. Consider the following graphs:

- $G$
- $\tilde{G}(v, 1, 2)$
- $\hat{G}(v, 1, 2)$

With the aid of MATLAB®, $\kappa(\hat{G}(v, 1, 2)) - \kappa(\tilde{G}(v, 1, 2)) \approx 0.1667$. Further, it is shown in Example 3.19 that $G$ is $(v, 1, 2)$-paradoxical.

Let us continue with the hypothesis and notation of Definition 3.6. To see if $G$ is $(v, k_1, k_2)$-paradoxical, we need to investigate $\kappa(\tilde{G}(v, k_1, k_2)) - \kappa(\hat{G}(v, k_1, k_2))$. So, we shall find formulae for $d^T \hat{G} F \hat{G} d_{\hat{G}}$ and $d^T \tilde{G} F \tilde{G} d_{\tilde{G}}$ in Lemmas 3.8 and 3.9, respectively.
Families of graphs with twin pendent paths and the Braess edge

Lemma 3.8. Let $P_k$ be a path with two pendant vertices $x$ and $y$ where $k \geq 2$, and $H$ be a connected graph. Suppose that $G$ is the graph obtained from $P_k$ and $H$ by identifying a vertex of $P_k$ and a vertex of $H$, say $v$. Let $\text{dist}_G(v, x) = k_1$ and $\text{dist}_G(v, y) = k_2$. Then,
\[
d^T_G F_G d_G = d^T_H F_H d_H + 4(k - 1)d^T_H f_H + \tau_H \left( \frac{4}{3}(k - 1)^3 + \frac{2}{3}(k - 1) + 4m_H(k_1^2 + k_2^2) \right).
\]

Proof. The conclusion is straightforward from (3.2) and Example 3.4.

Lemma 3.9. Let $C_k$ be a cycle of length $k$ where $k \geq 3$, and $H$ be a connected graph. Suppose that $G$ is the graph obtained from $C_k$ and $H$ by identifying a vertex of $C_k$ and a vertex of $H$, say $v$. Then,
\[
d^T_G F_G d_G = k d^T_H F_H d_H + 4k^2d^T_H f_H + \frac{2\tau_H}{3}(k + 2m_H)(k - 1)k(k + 1).
\]

Proof. The conclusion is readily established from (3.2) and Example 3.3.

Using Lemmas 3.8 and 3.9, we establish our desired equivalent condition as follows.

Theorem 3.10. Let $G$ be a connected graph with a vertex $v$. Suppose that $k_1, k_2 \geq 0$, $k_1 + k_2 \geq 2$ and $k - 1 = k_1 + k_2$. Then, $G$ is $(v, k_1, k_2)$-paradoxical if and only if
\[
k d^T_G (2f^T v - F_G) d_G + 4m_G^2 \tau_G (k - 1)(k_1 + k_2 - 1) + 2k_1 k_2)
\]
(3.3)
\[
+ \frac{2m_G \tau_G k}{3} (-5(k_1 + k_2)^3 + 4k_1 + k_2)^2 + 12k_1 k_2(k_1 + k_2 + 1)
\]
\[- 2\tau_G k^2((k_1 + k_2)(k_1 + k_2 - 1)) > 0.
\]

Proof. Evidently, $m_G = m_G + k - 1$, $\tau_G = m_G + k$ and $\tau_G = \tau_G$. Since $v$ is a cut-vertex in $\tilde{G}$, we have $\tau_G = k \tau_G$. Then,
\[
k(\tilde{G}(v, k_1, k_2)) - k(\tilde{G}(v, k_1, k_2)) = \frac{d^T_G F_G d_G}{4m_G \tau_G} - \frac{d^T_G F_G d_G}{4m_G \tau_G}
\]
(3.4)
\[
= \frac{(m_G + k - 1)d^T_G F_G d_G - k(m_G + k)d^T_G F_G d_G}{4k(m_G + k)(m_G + k - 1) \tau_G}.
\]

Then, $G$ is $(v, k_1, k_2)$-paradoxical if and only if
\[
(m_G + k - 1)d^T_G F_G d_G - k(m_G + k)d^T_G F_G d_G > 0.
\]

For simplicity, let $d = \tilde{G}, f^e = \tilde{G}, F = F_G, m = m_G$ and $\tau = \tau_G$. Using Lemmas 3.8 and 3.9, we have
\[
(m + k - 1)d^T_G F_G d_G - k(m + k)d^T_G F_G d_G
\]
(3.5)
\[
= (m + k - 1) \left( k d^T F d + 4k^2 d^T f^e + \frac{2\tau}{3}(k + 2m)(k - 1) k(k + 1) \right)
\]
\[- k(m + k) \left( d^T F d + 4(k - 1)d^T f^e + \frac{4}{3} \tau(k - 1)^3 + \frac{2}{3} \tau(k - 1) + 4m \tau(k_1^2 + k_2^2) \right)
\]
\[- \frac{2m \tau k}{3} ((k - 1)k(k + 1) + 2(k - 1)^2(k + 1) - 2(k - 1)^3 - (k - 1) - 6k(k_1^2 + k_2^2))
\]
\[+ \frac{2\tau k}{3} ((k - 1)^2k(k + 1) - 2(k - 1)^3 - k(k - 1)).
\]
Since $1^T d = 2m$, we have $4mk^2 F v = 2k^2 F^* 1^T d$. Then, one can check from $k - 1 = k_1 + k_2$ that the last expression in (3.5) can be recast as the left side of the inequality (3.3).

Now, we shall introduce the following notation to easily analyse the expression in (3.3). Let $G$ be a connected graph of order $n$ with $V(G) = \{1, \ldots, n\}$, and let

$$
\phi_G(v) := \frac{d_G^2}{2}(2f_G^* 1^T - F_G) d_G,
$$

$$
\phi_1(k_1, k_2) := -\frac{2}{3}(k_1 + k_2)(k_1 + k_2 - 1) + 2k_1k_2,
$$

$$
\phi_2(k_1, k_2) := -(k_1 + k_2)(5(k_1 + k_2)^2 - (k_1 + k_2) - 1) + 12k_1k_2(k_1 + k_2 + 1),
$$

$$
\phi_3(k_1, k_2) := -(k_1 + k_2 + 1)(k_1 + k_2)(k_1 + k_2 - 1)^2,
$$

where $v$, $k_1$ and $k_2$ are integers such that $1 \leq v \leq n$, $k_1, k_2 \geq 0$ and $k_1 + k_2 \geq 2$. Furthermore, let

$$
\Phi_G(v, k_1, k_2) := k\phi_G(v) + 4m_G^2 \tau_G k_1\phi_1(k_1, k_2) + \frac{2m_G \tau_G k}{3}\phi_2(k_1, k_2) + \frac{2\tau_G k}{3}\phi_3(k_1, k_2).
$$

By Theorem 3.10, $G$ is $(v, k_1, k_2)$-paradoxical if and only if $\Phi_G(v, k_1, k_2) > 0$. We simply write $\Phi_G(v, k_1, k_2)$ and $\phi_G(v)$ as $\Phi(v, k_1, k_2)$ and $\phi(v)$, respectively, if $G$ is clear from the context. Note that $\phi_i(k_1, k_2) = \phi_i(k_2, k_1)$ for $i = 1, 2, 3$. So, $\Phi_G(v, k_1, k_2) = \Phi_G(v, k_2, k_1)$.

**Remark 3.11.** A connected graph $G$ is $(v, k_1, k_2)$-paradoxical if and only if $G$ is $(v, k_2, k_1)$-paradoxical. Furthermore, $G$ is $(k_1, k_2)$-paradoxical if and only if $G$ is $(k_2, k_1)$-paradoxical.

**Signs of $\phi_i(k_1, k_2)$ for $i = 1, 2, 3$ and $\phi_G(v)$**. We shall consider the signs of $\phi_i(k_1, k_2)$ for $i = 1, 2, 3$ in terms of $k_1$ and $k_2$ and consider an upper bound for each $\phi_i(k_1, k_2)$. Evidently, $\phi_3(k_1, k_2)$ decreases as $k_1 + k_2$ increases, and so

$$
\phi_3(k_1, k_2) \leq -6 \text{ for any } k_1, k_2 \geq 0 \text{ where } k_1 + k_2 \geq 2,
$$

with equality if and only if $k_1 + k_2 = 2$. Next, $\phi_1(k_1, k_2)$ can be written as:

$$
\phi_1(k_1, k_2) = -\frac{2}{3}(k_1^2 - (k_1 + 1)k_1 + k_2^2 - k_2).
$$

Setting $\phi_1(k_1, k_2) = 0$, we have

$$
k_1 = \frac{1}{2} \left( (k_2 + 1) \pm \sqrt{-3k_2^2 + 6k_2 + 1} \right).
$$

Since $\phi_1(k_1, k_2)$ is symmetric, without loss of generality, we shall fix $k_2$ first. It follows from $-3k_2^2 + 6k_2 + 1 < 0$ that if $k_2 < 1 - \frac{2\sqrt{3}}{3} < 0$ or $k_2 > 1 + \frac{2\sqrt{3}}{3} > 2$, then $\phi_1(k_1, k_2) < 0$ for any $k_1 \geq 0$. Furthermore, if $k_2 = 1$, then $\phi_1(1, 1) = \frac{2}{3}$, $\phi_1(2, 1) = 0$ and $\phi_1(1, 1) < 0$ for $k_1 > 2$. Finally, for $k_2 = 2$, we have $\phi_1(0, 2) = -\frac{4}{3}$, $\phi_1(1, 2) = \phi_1(2, 2) = 0$ and $\phi_1(k_1, 2) < 0$ for $k_1 > 2$. Therefore, $\phi_1(k_1, k_2) > 0$ if and only if $(k_1, k_2) = (1, 1)$, $\phi_1(k_1, k_2) = 0$ if and only if $(k_1, k_2) \in \{(1, 2), (2, 1), (2, 2)\}$, and $\phi_1(k_1, k_2) < 0$ for any $k_1, k_2 \geq 0$ with $k_1 + k_2 \geq 2$ and $(k_1, k_2) \notin \{(1, 1), (1, 2), (2, 1), (2, 2)\}$.

**Remark 3.12.** We have $\frac{\partial \phi_1}{\partial k_1} = -\frac{4}{3}k_1 + \frac{2}{3}(k_2 + 1)$. Then, $\phi_1(2, 0) = -\frac{4}{3}$ and $\frac{\partial \phi_1}{\partial k_1} \big|_{k_2=0} < 0$ for $k_1 \geq 2$; $\phi_1(3, 1) = -2$ and $\frac{\partial \phi_1}{\partial k_1} \big|_{k_2=1} < 0$ for $k_1 \geq 3$; $\phi_1(3, 2) = -\frac{4}{3}$ and $\frac{\partial \phi_1}{\partial k_1} \big|_{k_2=2} < 0$ for $k_1 \geq 3$; finally, $\phi_1(k_2, k_2) = -\frac{2}{3}(k_2^2 - 2k_2) \leq -2$ for $k_2 \geq 3$ and $\frac{\partial \phi_1}{\partial k_1} < 0$ for $k_1 \geq k_2 \geq 3$. Hence, since $\phi_1(k_1, k_2)$ is
Furthermore, by computation, we have \( \phi_1(k_1, k_2) \leq -\frac{4}{5} \) for integers \( k_1, k_2 \geq 0 \) with \( k_1 + k_2 \geq 2 \) and \( (k_1, k_2) \notin \{(1, 1), (1, 2), (2, 1), (2, 2)\} \). Furthermore, by computation, we have \( \phi_1(3, 0) = \phi_1(4, 2) = -4 \). Therefore, \( \phi_1(k_1, k_2) \leq -2 \) for integers \( k_1, k_2 \geq 0 \) with \( k_1 + k_2 \geq 2 \) and \( (k_1, k_2) \notin \{(0, 2), (2, 0), (1, 1), (1, 2), (2, 1), (2, 2), (2, 3), (3, 2)\} \).

Putting \( k - 1 = k_1 + k_2 \geq 2 \), \( \phi_2(k_1, k_2) \) can be written as:

\[
\phi_2(k_1, k_2) = -12kk_1^2 + 12(k-1)k_1 - (k-1)(5k^2-11k+5).
\]

Setting \( \phi_2(k_1, k_2) = 0 \), we have

\[
k_1 = \frac{1}{12k} \left( 6k(k-1) \pm \sqrt{-12k(k-1)(2k^2-8k+5)} \right).
\]

Since \( 2k^2-8k+5 > 0 \) for all \( k \geq 4 \), \( \phi_2(1, k_2) < 0 \) for any \( k_1, k_2 \geq 0 \) with \( k_1 + k_2 \geq 3 \). For \( k = 3 \), we have \( \phi_2(1, 1) = 2 > 0 \) and \( \phi_2(2, 0) = -34 < 0 \). Let \( f(t) = -(t-1)(2t^2-8t+5) \) where \( t \) is real number. Then, for fixed \( t \geq 3 \), the maximum of \( \phi_2(t_1, t_2) \) for nonnegative numbers \( t_1 \) and \( t_2 \) with \( t_1 + t_2 = t - 1 \) is attained as \( f(t) \) at \( t_1 = \frac{t-1}{2} \). We can find that \( f(3) > 0, f(4) = -15 \) and \( f^t(t) < 0 \) for \( t \geq 4 \). From computation, we have \( \phi_2(0, 3) = -123 \) and \( \phi_2(1, 2) = -27 \). Hence,

\[(3.8) \quad \phi_2(k_1, k_2) < -15 \text{ for any } k_1, k_2 \geq 0 \text{ with } k_1 + k_2 \geq 2 \text{ and } (k_1, k_2) \neq (1, 1).
\]

We claim that for a non-trivial connected graph \( G \), \( \phi(v) = d^T(2f^v1^T - F)d > 0 \) for \( v = 1, \ldots, n \). In order to establish our claim, we first show that \( f^G_{i,j} \) is a metric on the vertex set of \( G \) by using the resistance distance (see \cite{14} for an introduction). Let \( L \) be the Laplacian matrix of \( G \), and let \( L^\dagger = [\ell^\dagger_{i,j}]_{n \times n} \) be the Moore–Penrose inverse of \( L \). Then, the resistance distance \( \Omega_{i,j} \) between vertices \( i \) and \( j \) of \( G \) is represented (see \cite{15}) as:

\[
\Omega_{i,j} = \ell^\dagger_{i,i} + \ell^\dagger_{j,j} - \ell^\dagger_{i,j} - \ell^\dagger_{j,i}.
\]

Moreover, the resistance distance is a metric on \( V(G) \) (see \cite{2}). As proved in \cite{7}, the number \( f^G_{i,j} \) of 2-tree spanning forests of \( G \) having \( i \) and \( j \) in different trees is

\[
f^G_{i,j} = \tau_G \Omega_{i,j}.
\]

Therefore, we have the following properties endowed by the metric \( \Omega_{i,j} \):

(i) \( f^G_{i,j} \geq 0 \), with equality if and only if \( i = j \);

(ii) \( f^G_{i,i} = f^G_{j,j} \) for all \( i, j \);

(iii) for any \( i, j, k \), \( f^G_{i,j} \leq f^G_{i,k} + f^G_{k,j} \), with equality \cite{4} if and only if either all paths in \( G \) from \( i \) to \( j \) pass through \( k \) or \( k \) is one of \( i \) and \( j \).

Let \( X = 2f^v1^T - F \), and \( Q = [q_{i,j}] = \frac{X+X^T}{4} \). Then,

\[
d^T X d = \frac{1}{2} (d^T X d + d^T X^T d) = 2d^T Q d.
\]

Since \( 2Q = f^v1^T + 1(f^v)^T - F \), we have \( 2q_{i,j} = f_{i,v} + f_{v,j} - f_{i,j} \geq 0 \). Since \( G \) is connected, if \( i \neq v \), then there exists a 2-tree spanning forest having \( i \) and \( v \) in different trees, that is, \( f_{i,v} > 0 \). For a non-trivial connected graph \( G \), there exists a vertex \( i \) with \( i \neq v \) such that \( 2q_{i,v} = f_{i,v} + f_{v,i} > 0 \). Hence, \( Q \) is a non-negative symmetric matrix with \( Q \neq 0 \). Since \( d > 0 \), we have \( d^T Q d > 0 \). Therefore, \( d^T(2f^v1^T - F) d > 0 \).
Recall that given a connected graph $G$ of order $n$ where $n \geq 2$, $G$ is $(v, k_1, k_2)$-paradoxical if and only if $\Phi(v, k_1, k_2) > 0$, where $1 \leq v \leq n$ and integers $k_1, k_2 \geq 0$ with $k_1 + k_2 \geq 2$. We have seen that $\phi(v) > 0$ for any $1 \leq v \leq n$ regardless of $k_1$ and $k_2$; $\phi_1(k_1, k_2) > 0$ if and only if $(k_1, k_2) \in \{(1, 1), (1, 2), (2, 1), (2, 2)\}$; $\phi_2(k_1, k_2) < 0$ for any $k_1, k_2$ with $(k_1, k_2) \neq (1, 1)$; and $\phi_3(k_1, k_2) < 0$ for any $k_1, k_2$. Hence, $\phi(v)$ must have a relatively larger quantity in order for $G$ to be $(v, k_1, k_2)$-paradoxical.

Consider the case $k_1 = k_2 = 1$. Then, $\Phi(v, 1, 1) = 3\phi(v) + 8m_G^2\tau_G + 4m_G\tau_G - 12\tau_G$. Clearly, $\Phi(v, 1, 1) > 0$ for any non-trivial connected graph $G$ and any vertex $v$ of $G$. Hence, we have the following result.

**Theorem 3.13** ([8]). Let $G$ be a connected graph of order $n$ where $n \geq 2$. Then, $G$ is $(1, 1)$-paradoxical.

**Combinatorial interpretation for** $f_2^G1^T + 1(f_2^G)^T - F_G$. Let $G$ be a non-trivial connected graph with a vertex $v$. We now discuss a combinatorial interpretation for $q_{i,j}$ where $q_{i,j} = \frac{1}{2}(f_{i,v}^G + f_{j,v}^G - f_{i,j}^G)$. Denote by $\mathcal{F}_G(i, j; v)$ (or equivalently $\mathcal{F}_G(v, i, j)$) the set of all spanning forests consisting of two trees in $G$, one of which contains vertices $i$ and $j$ and the other of which contains a vertex $v$. Then, we have

\[
|\mathcal{F}_G(i; j)| = |\mathcal{F}_G(i, v; j)| + |\mathcal{F}_G(i, v; j)|,
\]

\[
|\mathcal{F}_G(i; v)| = |\mathcal{F}_G(i, j; v)| + |\mathcal{F}_G(i, j; v)|,
\]

\[
|\mathcal{F}_G(v; j)| = |\mathcal{F}_G(i, v, j)| + |\mathcal{F}_G(v, i, j)|.
\]

It follows that $2q_{i,j} = f_{i,v} + f_{j,v} - f_{i,j}$, that is, $q_{i,j}$ is the number of 2-tree spanning forests of $G$ having $i$, $j$ in one tree and $v$ in the other. Thus, we define $Q_{G,v}$ as the matrix $Q_{G,v} = [q_{i,j}]$ associated to $G$ and $v$. Then,

\[
Q_{G,v} = \frac{1}{2}(f^v1^T + 1(f^v)^T - F), \quad \phi_G(v) = d^T(2f^v1^T - F)d = 2d^TQ_{G,v}d.
\]

**Remark 3.14.** Let $G$ be a connected graph with a vertex $v$. Let $Q_{G,v} = [q_{i,j}]$. Since $2q_{i,j} = f_{i,v} + f_{j,v} - f_{i,j}$, we have $q_{i,j} = 0$ whenever $v = i$ or $v = j$. Suppose that $v$ is a cut-vertex. If there is no path from $i$ to $j$ with $i \neq v$ and $j \neq v$ in $G - v$, then by the combinatorial interpretation for $q_{i,j}$, we obtain $q_{i,j} = 0$. Consider a branch $B$ of $G$ at $v$. Let $i, j \in V(B)$. For each forest in $\mathcal{F}_G(i, j; v)$, the subtree with the vertex $v$ in the forest must contain all vertices of $V(G) \setminus V(B)$. Thus, for the subgraph $G'$ induced by $V(G) \setminus V(B) \setminus \{v\}$, we have $|\mathcal{F}_G(i, j; v)| = \tau_{G'}|\mathcal{F}_B(i, j; v)|$. This implies that $G'$ is a tree if and only if $|\mathcal{F}_G(i, j; v)| = |\mathcal{F}_B(i, j; v)|$.

Given a tree $T$ with a vertex $v$, let $Q_{T,v} = [q_{i,j}]$. Consider two vertices $i$ and $j$ in $T$ with $i \neq v$ and $j \neq v$. For each forest in $\mathcal{F}_T(i, j; v)$, there is a subtree of the forest having $i$ and $j$. Then, all vertices $w_0, w_1, \ldots, w_{\text{dist}(i,j)}$ on the path with pendant vertices $i$ and $j$ must be contained in the subtree. Therefore, $q_{i,j} = \min\{\text{dist}(w, v) | p = 0, \ldots, \text{dist}(i, j)\}$. In particular, if $i = j$ then $q_{i,j} = \text{dist}(i, v)$.

Based on Remark 3.14, let us consider the following example.

**Example 3.15.** Consider the path $P_6 = (1, \ldots, 6)$. Let $Q_{P_6,v} = [q_{i,j}]$ where $v = 3$. Evidently, $q_{3,3} = q_{3,4} = 0$ for $1 \leq i \leq 6$. Since $v$ is a cut vertex, we have $q_{i,j} = 0$ for $i \in \{1, 2\}$ and $j \in \{4, 5, 6\}$. By the argument in the second paragraph of Remark 3.14, we have

\[
Q_{P_6,v} = \begin{bmatrix}
2 & 1 & 0 & 0 & 0 & 0 \\
1 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 1 & 1 \\
0 & 0 & 0 & 1 & 2 & 2 \\
0 & 0 & 0 & 1 & 3 & 3
\end{bmatrix}.
\]
While the combinatorial interpretation for entries of $Q_{G,v}$ is given, we mainly focus on the computation of $d^TQ_{G,v}d$ in the rest of this section, but the combinatorial interpretation is used more in Section 5.

**Several examples.** We now find conditions for $K_n$, $C_n$, $P_n$ or $S_n$ to be $(v,k_1,k_2)$-paradoxical or $(k_1,k_2)$-paradoxical. For simplicity, set $k - 1 = k_1 + k_2$ and $\phi_i = \phi_i(k_1,k_2)$ for $i = 1,2,3$. Note that $\phi_G(v) = d^T(2f^v1^T - F)d = 2d^TQ_{G,v}d$ and $\phi_i(k_1, k_2) = \phi_i(k_2,k_1)$ for $i = 1,2,3$. We compute $\phi_G(v)$ by using $F$ and $f^v$ for $G = K_n$ or $G = C_n$, and by directly finding $Q_{G,v}$ for $G = P_n$ or $G = S_n$. For convenience, the following quantities are computed in advance: $\phi_2(1,2) = -27$, $\phi_3(1,2) = -48$, $\phi_2(2,2) = -60$ and $\phi_3(2,2) = -180$.

**Example 3.16.** Consider a complete graph $K_n$ on $n$ vertices. Let $v$ be a vertex of $K_n$. Then, from $\phi(v) = d^T(2f^v1^T - F)d$ and Example 3.2, it is readily seen that 

$$\phi(v) = 2n^{n-2}(n-1)^3 = 2n^3(n-1)^3.$$ 

Using (3.6) with $m = \frac{n(n-1)}{2}$, we obtain 

$$\Phi_{K_n}(v, k_1, k_2) = \tau k \left(2(n-1)^3 + n^2(n-1)^2\phi_1 + \frac{1}{3}n(n-1)\phi_2 + \frac{2}{3}\phi_3\right).$$

Suppose that $(k_1, k_2) \notin \{(1,1), (1,2), (2,1), (2,2)\}$. By Remark 3.12, $\phi_1 \leq -\frac{4}{3}$. From (3.8), we have $\phi_2 < -15$. By (3.7), $\phi_3 \leq -6$. Hence, 

$$\Phi(v, k_1, k_2) < \tau k \left(-\frac{4}{3}n^4 + \frac{14}{3}n^3 - \frac{37}{3}n^2 + 11n - 6\right).$$

One can verify that $-\frac{4}{3}n^4 + \frac{14}{3}n^3 - \frac{37}{3}n^2 + 11n - 6 < 0$ for $n \geq 1$. Thus, if $(k_1, k_2) \notin \{(1,1), (1,2), (2,1), (2,2)\}$, then $K_n$ is not $(v, k_1, k_2)$-paradoxical for any $n \geq 1$.

Consider $(k_1, k_2) = (1,2)$ and $(k_1, k_2) = (2,2)$. Then, 

$$\Phi(v, 1, 2) = 4\tau \left(2(n-1)^3 - 9n(n-1) - 32\right),$$

$$\Phi(v, 2, 2) = 5\tau \left(2(n-1)^3 - 20n(n-1) - 120\right).$$

Using the derivatives of $\frac{\Phi(v, 1, 2)}{4\tau}$ and $\frac{\Phi(v, 2, 2)}{10\tau}$ with respect to $n$, it can be checked that $\Phi(v, 1, 2) > 0$ if and only if $n \geq 7$; $\Phi(v, 2, 2) > 0$ if and only if $n \geq 13$. Hence, $K_n$ is $(1,2)$-paradoxical for $n \geq 7$, and $(2,2)$-paradoxical for $n \geq 13$.

**Example 3.17.** Given a cycle $C_n$ with a vertex $v$, from $\phi(v) = d^T(2f^v1^T - F)d$ and Example 3.3, we have $\phi(v) = \frac{2}{3}(n-1)n^2(n+1) = \frac{2}{3}(n-1)n(n+1)$. Using (3.6), we find 

$$\Phi_{C_n}(v, k_1, k_2) = \tau k \left(\frac{2}{3}(n-1)n(n+1) + 4n^2\phi_1 + \frac{2}{3}n\phi_2 + \frac{2}{3}\phi_3\right).$$

We observe that the term of the highest degree about $n$ in $\frac{\Phi_{C_n}(v, k_1, k_2)}{\tau k}$ has a positive coefficient. This implies that given $k_1, k_2 \geq 0$ with $k_1 + k_2 \geq 2$, $C_n$ is $(k_1, k_2)$-paradoxical for sufficiently large $n$. Consider $(k_1, k_2) = (1, 2)$ and $(k_1, k_2) = (2, 2)$. Then, 

$$\Phi(v, 1, 2) = 4\tau \left(\frac{2}{3}(n-1)n(n+1) - 18n - 32\right),$$

$$\Phi(v, 2, 2) = 5\tau \left(\frac{2}{3}(n-1)n(n+1) - 40n - 120\right).$$
One can verify that $\Phi(v, 1, 2) \geq 0$ for $n \geq 6$ with equality if and only if $n = 6$; $\Phi(v, 2, 2) \geq 0$ for $n \geq 9$ with equality if and only if $n = 9$. Hence, $C_n$ is $(1, 2)$-paradoxical for $n \geq 7$, and $(2, 2)$-paradoxical for $n \geq 10$.

**Example 3.18.** Consider the path $P_n = (1, \ldots, n)$ with a vertex $v$. By Remark 3.14 and Example 3.15, we have

$$Q_{P_n,v} = \begin{bmatrix} M_1 & 0 \\ 0 & M_2 \end{bmatrix},$$

where $M_1 = [\min\{v-i, v-j\}]_{1 \leq i, j \leq v}$ and $M_2 = [\min\{i, j\}]_{1 \leq i, j \leq n-v}$. We have $d_{P_n} = 21_n - e_1 - e_n$. Then,

$$d^T Q_{P_n,v} d = 41^T Q_{P_n,v} 1 + (M_1)_{1,1} + (M_2)_{n-v,n-v} - 41^T Q_{P_n,v} e_1 - 41^T Q_{P_n,v} e_n$$

$$= 4 \left( \sum_{k=1}^{v-1} k^2 + \sum_{k=1}^{n-v} k^2 \right) + n - 1 - 2v(v-1) - 2(n-v)(n-v+1)$$

$$= 4(n-1)v^2 - 4(n^2 - 1)v + \frac{4}{3}n^3 - \frac{1}{3}n - 1.$$

The minimum of $d^T Q_{P_n,v} d$ is attained as $\frac{1}{3}n(n-1)(n-2)$ if $n$ is odd, and as $\frac{1}{3}n^3 - n^2 + \frac{2}{3}n - 1$ if $n$ is even. The maximum of $d^T Q_{P_n,v} d$ is $\frac{1}{3}(n-1)(2n-1)(2n-3)$ at $v = 1$ or $v = n$.

By (3.6) and the minimum of $\phi(v) = 2d^T Q_{P_n,v} d$, we have

$$\Phi_{P_n}(v, k_1, k_2) \geq k \left( \frac{2}{3}n(n-1)(n-2) + (n-1)^2 \phi_1 + \frac{2}{3}(n-1) \phi_2 + \frac{2}{3} \phi_3 \right).$$

By a similar argument as in Example 3.17, given $k_1, k_2 \geq 0$ with $k_1 + k_2 \geq 2$, $P_n$ is $(k_1, k_2)$-paradoxical for sufficiently large $n$.

**Example 3.19.** Consider a star $S_n$ of order $n$ with a vertex $v$. Using Remark 3.14, it can be checked that

$$Q_{S_n,v} = \begin{cases} J + \begin{bmatrix} I_{n-1} & 0 \\ 0 & 0 \end{bmatrix} - e_v 1^T, & \text{if } \deg(v) = 1, \\
\begin{bmatrix} I_{n-1} & 0 \\ 0 & 0 \end{bmatrix}, & \text{if } \deg(v) = n-1. \end{cases}$$

Hence,

$$d^T Q_{S_n,v} d = \begin{cases} (n-1)(4n-7), & \text{if } \deg(v) = 1, \\
n-1, & \text{if } \deg(v) = n-1. \end{cases}$$

Suppose that $v$ is the centre vertex. Then, $n \geq 3$. By (3.6) and $\phi(v) = 2d^T Q_{S_n,v} d$, we have

$$\Phi_{S_n}(v, k_1, k_2) = k \left( 2(n-1) + 4(n-1)^2 \phi_1 + \frac{2}{3}(n-1) \phi_2 + \frac{2}{3} \phi_3 \right).$$

Let $(k_1, k_2) \neq (1, 1)$. Clearly, $\phi_1 \leq 0$. By (3.8) and (3.7), we have $\phi_2 < -15$ and $\phi_3 \leq -6$, respectively. So, $\Phi(v, k_1, k_2) < -4k(2n-1)$. Hence, if $S_n$ is $(v, k_1, k_2)$-paradoxical where $v$ is the centre vertex of $S_n$, then $(k_1, k_2) = (1, 1)$ and $n \geq 3$. 

E. Kim
Families of graphs with twin pendent paths and the Braess edge

Suppose that \( v \) is a pendent vertex. Then,

\[
\Phi_{S_n}(v, k_1, k_2) = \frac{k}{2} \left( 2(n-1)(4n-7) + 4(n-1)^2 \phi_1 + \frac{2}{3} (n-1) \phi_2 + \frac{2}{3} \phi_3 \right).
\]

We have \( \phi_1(2,0) = -\frac{4}{3}, \phi_2(2,0) = -34 \) and \( \phi_3(2,0) = -6; \phi_1(3,2) = -\frac{4}{3}, \phi_2(3,2) = -163 \) and \( \phi_3(3,2) = -480 \). One can check that \( \Phi(v, 2, 0) = 8n^2 - 102n + 82 > 0 \) for \( n \geq 12 \); \( \Phi(v, 2, 1) = 32n^2 - 160n > 0 \) for \( n \geq 6 \); \( \Phi(v, 2, 2) = 40n^2 - 310n - 330 > 0 \) for \( n \geq 9 \); and \( \Phi(v, 3, 2) = 16n^2 - 720n - 1216 > 0 \) for \( n \geq 47 \).

Let

\[ A = \{(0,2), (2,0), (1,1), (1,2), (2,1), (2,2), (2,3), (3,2)\} \]

Suppose that \( (k_1, k_2) \notin A \). By Remark 3.12, we have \( \phi_1(k_1, k_2) \leq -2 \). From (3.8) and (3.7), \( \phi_2 < -15 \) and \( \phi_3 \leq -6 \), respectively. Hence, \( \Phi(v, k_1, k_2) < -k(16n - 12) \). Therefore, if \( S_n \) is \((v, k_1, k_2)\)-paradoxical for a pendent vertex \( v \), then \( k_1, k_2 \) and \( n \) satisfy one of the following: (i) \( (k_1, k_2) = (1,1), n \geq 2 \); (ii) \( (k_1, k_2) \in \{(0,2), (2,0)\}, n \geq 12 \); (iii) \( (k_1, k_2) \in \{(1,2), (2,1)\}, n \geq 6 \); (iv) \( (k_1, k_2) = (2,2), n \geq 9 \); and (v) \( (k_1, k_2) \in \{(2,3), (3,2)\}, n \geq 47 \).

4. Asymptotic behaviour of a sequence of graphs with twin pendent paths regarding the Braess edge. We have seen the families of complete graphs, cycles, stars and paths in the previous section, and we have observed their asymptotic behaviours with respect to the property of being \((v, k_1, k_2)\)-paradoxical as the orders of graphs increase. In particular, from Examples 3.17 and 3.18, if for any non-negative integers \( k_1 \) and \( k_2 \) with \( k_1 + k_2 \geq 2 \), any graph in a family of cycles or paths has sufficiently large order relative to \( k_1 \) and \( k_2 \), then it is \((k_1, k_2)\)-paradoxical. This idea is formalised for a specified vertex, and a tool for finding such families is described in this section.

Definition 4.1. Let \( G^v \) be a sequence of graphs \( G_1, G_2, \ldots \) where for each \( n \geq 1 \), \( G_n \) is a connected graph of order \( n \) with a specified vertex \( v \). Fix integers \( k_1, k_2 \geq 0 \) with \( k_1 + k_2 \geq 2 \). The sequence \( G^v \) is asymptotically \((k_1, k_2)\)-paradoxical if there exists \( N > 0 \) such that \( G_n \) is \((v, k_1, k_2)\)-paradoxical for all \( n \geq N \). The sequence \( G^v \) is asymptotically paradoxical if for any integers \( l_1, l_2 \geq 0 \) with \( l_1 + l_2 \geq 2 \), \( G^v \) is asymptotically \((l_1, l_2)\)-paradoxical.

In what follows, \( G^v = (G_n)^v \) denotes a sequence of connected graphs \( G_1, G_2, \ldots \) where for each \( n \geq 1 \), \( |V(G_n)| = n \) and \( v \in V(G_n) \).

Example 4.2. From Theorem 3.13, any sequence \( G^v = (G_n)^v \) is asymptotically \((1,1)\)-paradoxical.

Example 4.3. Let \( G_1^v = (K_n)^v, G_2^v = (C_n)^v, G_3^v = (P_n)^v \) and \( G_4^v = (S_n)^v \). From Examples 3.16–3.19, \( G_1^v \) and \( G_3^v \) are asymptotically paradoxical, but \( G_2^v \) and \( G_4^v \) are not. In particular, \( G_1^v \) is asymptotically \((k_1, k_2)\)-paradoxical if and only if \( (k_1, k_2) \in \{(1,1), (1,2), (2,1), (2,2)\} \). Consider \( G_3^v = (S_n)^v \). Suppose that there exists \( N > 0 \) such that \( v \) is a pendent vertex of \( S_n \) for all \( n \geq N \). Then, \( G_3^v \) is asymptotically \((k_1, k_2)\)-paradoxical if and only if \( (k_1, k_2) = (1,1) \) is in the set \( A \) described in Example 3.19. If there exists \( N > 0 \) such that \( v \) is the centre vertex of \( S_n \) for all \( n \geq N \), then \( G_4^v \) is asymptotically \((k_1, k_2)\)-paradoxical if and only if \( (k_1, k_2) = (1,1) \).

Consider a sequence \( G^v = (G_n)^v \). Examining the proof of Theorem 3.10 with (3.4), we find from (3.6) that
strictly increasing for $n$

Note that the first inequality is obtained by (3.8) and (3.7).

$G$ is paradoxical, then $N > G$.

Here is the main result in this section.

**Proposition 4.4.** Let $k_1, k_2$ be non-negative integers with $k_1 + k_2 \geq 2$ and $(k_1, k_2) \neq (1, 1)$. Given a sequence $G(n)$, suppose that \( \frac{\phi_{G_{N+1}}(v)}{4m_{G_{N+1}}^2 \tau_{G_{N+1}}} \geq \frac{\phi_{G_{N}}(v)}{4m_{G_{N}}^2 \tau_{G_{N}}} \) for some $N > 0$. If $G_N$ is $(v, k_1, k_2)$-paradoxical, then $G_{N+1}$ is $(v, k_1, k_2)$-paradoxical. This implies that if $G_{N_0}$ is $(v, k_1, k_2)$-paradoxical for some $N_0 > 0$, and if $\frac{\phi_{G_{N}}(v)}{4m_{G_{N}}^2 \tau_{G_{N}}}$ is non-decreasing for $n \geq N_0$, then $G_n$ is $(v, k_1, k_2)$-paradoxical for all $n \geq N_0$—that is, $G(n)$ is asymptotically $(k_1, k_2)$-paradoxical.

**Proof.** We only need to show that if $\Phi_{G_{N}}(v, k_1, k_2) > 0$ then $\Phi_{G_{N+1}}(v, k_1, k_2) > 0$. We note that $m_{G_{N+1}} > m_{G_{N}}$. From the numerator in (4.9), it follows that

\[
\Phi_{G_{N+1}}(v, k_1, k_2) = 4m_{G_{N+1}}^2 \tau_{G_{N+1}} \left( \frac{\phi_{G_{N+1}}(v)}{4m_{G_{N+1}}^2 \tau_{G_{N+1}}} + \frac{\phi_1(k_1, k_2)}{6m_{G_{N+1}}} + \frac{\phi_2(k_1, k_2)}{6m_{G_{N+1}}} \right)
\]

\[
> 4m_{G_{N+1}}^2 \tau_{G_{N+1}} \left( \frac{\phi_{G_{N}}(v)}{4m_{G_{N}}^2 \tau_{G_{N}}} + \frac{\phi_1(k_1, k_2)}{6m_{G_{N}}} + \frac{\phi_2(k_1, k_2)}{6m_{G_{N}}} \right)
\]

\[
\geq 4m_{G_{N+1}}^2 \tau_{G_{N+1}} \left( \frac{\phi_{G_{N}}(v)}{4m_{G_{N}}^2 \tau_{G_{N}}} + \frac{\phi_1(k_1, k_2)}{6m_{G_{N}}} + \frac{\phi_2(k_1, k_2)}{6m_{G_{N}}} \right)
\]

\[
= 4m_{G_{N+1}}^2 \tau_{G_{N+1}} \frac{\Phi_{G_{N}}(v, k_1, k_2)}{4m_{G_{N}}^2 \tau_{G_{N}}} > 0.
\]

Note that the first inequality is obtained by (3.8) and (3.7).

**Example 4.5.** Let $(k_1, k_2) = (1, 2)$. Consider $G(n) = (P_n)^v$ where for each $n \geq 2$, $v$ is a pendant vertex of $P_n$. Examining Example 3.18, it can be seen that $\Phi_{P_k}(v, 1, 2) < 0$ and $\Phi_{P_k}(v, 1, 2) > 0$; and $\frac{\phi_{P_k}(v)}{4m_{P_k}^2 \tau_{P_k}}$ is strictly increasing for $n \geq 2$. Therefore, by Proposition 4.4, $P_n$ is $(v, 1, 2)$-paradoxical for $n \geq 5$.

Here is the main result in this section.

**Theorem 4.6.** Given a sequence $G(n)^v$, $G(n)$ is asymptotically paradoxical if and only if $\frac{\phi_{G_n}(v)}{4m_{G_n}^2 \tau_{G_n}} \to \infty$ as $n \to \infty$.  

\[
\kappa(G_n(v, k_1, k_2)) - \kappa(G_n(v, k_1, k_2)) = \frac{\Phi_{G_n}(v, k_1, k_2)}{4k(m_{G_n} + k)(m_{G_n} + k - 1)\tau_{G_n}}
\]

\[
= \frac{\phi_{G_n}(v) + 4m_{G_n}^2 \tau_{G_n} \phi_1(k_1, k_2) + \frac{2m_{G_n} \tau_{G_n}}{4} \phi_2(k_1, k_2) + \frac{2\tau_{G_n}}{4} \phi_3(k_1, k_2)}{4(m_{G_n} + k)(m_{G_n} + k - 1)\tau_{G_n}}.
\]

(4.9)
Proof. We shall prove the sufficiency by contrapositive. Suppose that \( \frac{\phi_{G_n}(v)}{4m_{G_n}^2 \tau_{G_n}} \) is bounded, say \( 0 < \frac{\phi_{G_n}(v)}{4m_{G_n}^2 \tau_{G_n}} \leq L \) for any \( n \geq 2 \) and for some \( L > 0 \). Then, from (4.9), we have

\[
\kappa(\tilde{G}_n(v, k_1, k_2)) - \kappa(G_n(v, k_1, k_2)) < \frac{\phi_G(v) + 4m_{G_n}^2 \tau_{G_n} \phi_1(k_1, k_2) + 2m_{G_n} \tau_{G_n} \phi_2(k_1, k_2) + 2\tau_{G_n} \phi_3(k_1, k_2)}{4m_{G_n}^2 \tau_{G_n}} \\
\leq L + \frac{\phi_1(k_1, k_2) + \phi_2(k_1, k_2) + \phi_3(k_1, k_2)}{6m_{G_n}}.
\]

Considering Remark 3.12, (3.8) and (3.7), there exist integers \( K_1 \geq 0 \) and \( K_2 \geq 0 \) with \( K_1 + K_2 \geq 2 \) such that \( \kappa(G_n(v, K_1, K_2)) - \kappa(G_n(v, K_1, K_2)) < 0 \) for all \( n \geq 2 \)—that is, \( G^v \) is not asymptotically paradoxical.

Suppose that \( \frac{\phi_{G_n}(v)}{4m_{G_n}^2 \tau_{G_n}} \) diverges to infinity. Fix \( k_1, k_2 \geq 0 \) with \( k_1 + k_2 \geq 2 \). Since \( G_n \) is connected for all \( n \geq 1 \), \( m_{G_n} \) goes to infinity as \( n \to \infty \). It follows from (4.9) that

\[
\lim_{n \to \infty} \left( \kappa(\tilde{G}_n(v, k_1, k_2)) - \kappa(G_n(v, k_1, k_2)) \right) = \infty.
\]

Therefore, \( G^v \) is asymptotically paradoxical.

**Example 4.7.** Revisit Examples 3.16–3.19. One can verify that as \( n \to \infty \), we have \( \frac{\phi_{K_n}(v)}{4m_{K_n}^2 \tau_{K_n}} \to 0; \frac{\phi_{P_n}(v)}{4m_{P_n}^2 \tau_{P_n}} \to \infty; \frac{\phi_{P_n}(v)}{4m_{P_n}^2 \tau_{P_n}} \to 2 \) where \( v \) is a pendant vertex of \( S_n \); and \( \frac{\phi_{P_n}(v)}{4m_{P_n}^2 \tau_{P_n}} \to 0 \) where \( v \) is the centre vertex of \( S_n \). By Theorem 4.6, the sequences \( (C_n)^v \) and \( (P_n)^v \) are asymptotically paradoxical.

Now we shall construct \((v, k_1, k_2)\)-paradoxical graphs from a connected graph that is not \((v, k_1, k_2)\)-paradoxical, by using an asymptotically paradoxical sequence. Given a connected graph \( G \) with a vertex \( v \), suppose that \( G \) is not \((v, k_1, k_2)\)-paradoxical. Adding new vertices and edges to \( G \), we shall make the resulting graph \((v, k_1, k_2)\)-paradoxical.

Note that the case of the equality in the following proposition is used in Section 5.

**Proposition 4.8.** Let \( G \) be a connected graph, and \( v \) be a cut-vertex. Suppose that there are \( \ell \) branches \( B_1, \ldots, B_{\ell} \) of \( G \) at \( v \). Then,

\[
(4.10) \quad d_G^T Q_{G,v} d_G = \sum_{k=1}^\ell \tau_{G_k}^r d_{B_k}^T Q_{B_k,v} d_{B_k} \geq \sum_{k=1}^\ell d_{B_k}^T Q_{B_k,v} d_{B_k},
\]

where \( G_k \) is the subgraph induced by \( V(G) \setminus (V(B_k) \setminus \{v\}) \). This implies that \( \phi_G(v) \geq \sum_{k=1}^\ell \phi_{B_k}(v) \). Moreover, the two sides are equal if and only if \( G \) is a tree.

**Proof.** Let \( Q_{G,v} = [q_{i,j}] \). By Remark 3.14, if \( i = v \) or \( j = v \), then \( q_{i,j} = 0 \). Consider \( i \neq v \) and \( j \neq v \). Suppose that \( i \in V(B_k) \) and \( j \in V(B_k) \) for \( k_1 \neq k_2 \). Since \( v \) is a cut-vertex of \( G \), we find from Remark 3.14 that \( q_{i,j} = 0 \). Hence, for \( k = 1, \ldots, \ell \), the submatrix of \( Q_{G,v} \) whose rows and columns are indexed by \( V(B_k) \) and \( V(G) \setminus V(B_k) \), respectively, is the zero matrix. For \( k = 1, \ldots, \ell \), assume \( i, j \in V(B_k) \). Since \( v \) is a cut-vertex, by Remark 3.14, we have \( |F_G(i,j,v)| = \tau_{G_k}^r |F_{B_k}(i,j,v)| \) where \( G_k \) is the subgraph induced by \( V(G) \setminus (V(B_k) \setminus \{v\}) \), with equality if and only if \( G_k \) is a tree. Therefore, the submatrix of \( Q_{G,v} \) whose rows and columns are indexed by the vertex set \( V(B_k) \) is \( \tau_{G_k}^r Q_{B_k,v} \).
Let $1 \leq k \leq \ell$. For $d_{B_k} = (d_i)_{i \in V(B_k)}$, let $\hat{d}_{B_k} = (\hat{d}_i)_{i \in V(G)}$ where $\hat{d}_i = d_i$ if $i \in V(B_k)$, and $\hat{d}_i = 0$ if $i \in V(G) \setminus V(B_k)$. Then, for $1 \leq k_1, k_2 \leq \ell$,
\[ \hat{d}^T_{B_k_1} Q G_v \hat{d}_{B_k_2} = d^T_{B_k_1} \hat{Q}_G v d_{B_k_2}, \]
where $\hat{Q}_G v$ is the submatrix of $Q_G v$ whose rows and columns are indexed by $V(B_{k_1})$ and $V(B_{k_2})$, respectively. If $k_1 \neq k_2$ then $d^T_{B_k_1} \hat{Q}_G v d_{B_k_2} = 0$. Furthermore, $d^T_{B_k_1} \hat{Q}_G v d_{B_k_2} = \tau_{G_{v}} d^T_{B_k_1} Q B_{k_1} v d_{B_k_1}$. Evidently, $d_G = \sum_{k=1}^{\ell} d_{B_k}$. Therefore, the desired result follows.

**Proposition 4.9.** Let $H_i$ be a connected graph with a vertex $v_i$ for $i = 1, \ldots, \ell$. Suppose that a sequence $G_i^v = (G_n^v)^v$ is asymptotically paradoxical. Consider a sequence $(G_i^v)^v = (G_n^v)^v$ where for $1 \leq n \leq \sum_{i=1}^{\ell} |V(H_i)|$, $G_n^v = G_n$, and for $n > \sum_{i=1}^{\ell} |V(H_i)|$, $G_n^v$ is the graph obtained from $H_1, \ldots, H_\ell$ and $G_n - \sum_{i=1}^{\ell} |V(H_i)|$ by identifying the vertices $v_1, \ldots, v_{\ell}$. Then, $(G_i^v)^v$ is asymptotically paradoxical.

**Proof.** Suppose that $n > \sum_{i=1}^{\ell} |V(H_i)|$. Let $n_0 = n - \sum_{i=1}^{\ell} |V(H_i)|$. Since $v$ is a cut-vertex in $G_n^v$, we have $\tau_{G_n^v} = \tau_{G_n^v} \tau_{H_1} \cdots \tau_{H_\ell}$. Using Proposition 4.8, we obtain
\[ \frac{\phi_{G_n^v}(v)}{4m_{G_n^v}^2 \tau_{G_n^v}} \geq \frac{\phi_{G_n^v}(v) + \sum_{i=1}^{\ell} \phi_{H_i}(v_i)}{4(m_{G_n^v} + \sum_{i=1}^{\ell} m_{H_i})^2 \tau_{G_n^v} \tau_{H_1} \cdots \tau_{H_\ell}}. \]
As $n \to \infty$, we have $n_0 \to \infty$. Since $(G_i^v)^v$ is asymptotically paradoxical, by Theorem 4.6 we obtain $\frac{\phi_{G_n^v}(v)}{4m_{G_n^v}^2 \tau_{G_n^v}} \to \infty$ as $n \to \infty$. It follows that $\frac{\phi_{G_n^v}(v)}{4m_{G_n^v}^2 \tau_{G_n^v}} \to \infty$ as $n \to \infty$. Therefore, $(G_i^v)^v$ is asymptotically paradoxical.

**Remark 4.10.** Let a sequence $G_i^v = (G_n^v)^v$ be asymptotically paradoxical. Suppose that a connected graph $H$ with a vertex $w$ is not $(w, k_1, k_2)$-paradoxical for some integers $k_1$ and $k_2$ with $k_1 + k_2 \geq 2$. Proposition 4.9 tells that regardless of the number of branches of $H$ at $w$, we can obtain a $(v, k_1, k_2)$-paradoxical graph from $H$ by identifying $w$ and the vertex $v$ of $G_n$ for sufficiently large order $n$.

**Example 4.11.** Adopting the notation in Remark 4.10, consider the following graph $H$:

```
   w
  /\  \
 \  \
 H
```

One can check from computation that $\phi_H(w) = 2d_H^T Q_{H,w} d_H = 118$ and $\Phi_H(w, 1, 2) < 0$. So, $H$ is not $(w, 1, 2)$-paradoxical. From Example 4.7, $G^v = (P_n^v)^v$ is asymptotically paradoxical. For ease of exposition, we assume that for each $n \geq 2$, $v$ is a pendant vertex of $P_n$. Suppose that $G_n^v$ is the graph obtained from $H$ and $P_n$ by identifying $w$ and $v$ as $v$. As discussed in Remark 4.10, there must be some $N_0 > 0$ such that $G_n^v$ is $(v, 1, 2)$-paradoxical for all $n \geq N_0$. We shall minimise such an $N_0$. Using Proposition 4.8 and Example 3.18, we have
\[ \phi_{G_n^v}(v) = 2d_{G_n^v}^T Q_{G_n^v,v} d_{G_n^v} = 2d_H^T Q_{H,w} d_H + 6d_P^T Q_{P_n,v} d_P = 118 + 2(n-1)(2n-1)(2n-3). \]
By computation of $\Phi_{G_n^v}(v, 1, 2)$ for $n = 2, \ldots, 5$, $G_2^v$, $G_3^v$, and $G_4^v$ are not $(v, 1, 2)$-paradoxical, and $G_n^v$ is $(v, 1, 2)$-paradoxical. Furthermore, it can be checked that $\frac{\phi_{G_n^v}(v)}{4m_{G_n^v}^2 \tau_{G_n^v}}$ is strictly increasing for $n \geq 5$. Hence,
Families of graphs with twin pendent paths and the Braess edge

by Proposition 4.4, \( G'_n \) is \( (v, 1, 2) \)-paradoxical for all \( n \geq 5 \). In other words, we can construct a \( (v, 1, 2) \)-paradoxical graph from \( H \) and a path of length at least 4 by identifying \( w \) and a pendent vertex of the path.

5. Asymptotically paradoxical sequences of trees. We begin with presenting an outline of this section. Throughout this section, we shall consider sequences \( G^n = (T_n)_v \) of trees, where for each \( n \geq 2 \), \( T_n \) is obtained from \( T_{n-1} \) by an addition of a new pendent vertex or a subdivision of an edge. Then, we examine asymptotic behaviour of such trees upon the addition of twin pendent paths; specifically, we investigate under what circumstances the sequences are asymptotically paradoxical. Considering Theorem 4.6, we need to understand \( \frac{\phi_{T_n}(v)}{4m_{T_n}^{-1}} v \). Recall that \( \phi_{T_n}(v) = 2d_{T_n}^T Q_{T_n,v} d_{T_n} \). To consider conditions for \( \frac{\phi_{T_n}(v)}{4m_{T_n}^{-1}} v \) to diverge to infinity, we shall find the minimum of \( d_{T_n}^T Q_{T_n,v} d_{T_n} \), provided the number of branches of \( T_n \) at \( v \) and the eccentricity of \( v \) in each branch are given (Proposition 5.3). With the minimum, we provide some condition in terms of the eccentricity of \( v \) in \( T_n \) and the number of branches of \( T_n \) at \( v \) satisfying some property, in order for the sequences to be asymptotically paradoxical (Theorem 5.6).

Here is a sketch of two steps to find the minimum of \( d_{T_n}^T Q_{T_n,v} d_{T_n} \). By Proposition 4.8, we only need to understand the minimum of \( d_{B}^T Q_{B,v} d_{B} \) where \( B \) is a branch of \( T_n \) at \( v \)—that is, the minimum of \( d_{T}^T Q_{T,v} d_{T} \) where \( T \) is a tree with a pendent vertex \( v \) and the eccentricity of \( v \) is given. This minimum is provided in (5.13) at the end of Step 1. By Proposition 4.8, we establish our desired result in Proposition 5.3 in Step 2.

**Step 1.** Let \( T \) be a tree of order \( n \) and \( v \) be a pendent vertex in \( T \). Suppose that \( \alpha \) is the eccentricity \( e_T(v) \) of \( v \) in \( T \). Then, there exists the path \( P = (v_0, v_1, \ldots, v_\alpha) \) of length \( \alpha \) in \( T \) where \( v_0 = v \). Evidently, \( v_0 \) and \( v_\alpha \) are pendent vertices in \( T \). Let \( T_0 \) and \( T_\alpha \) be the trees where \( V(T_0) = \{v_0\} \) and \( V(T_\alpha) = \{v_\alpha\} \). For \( k = 1, \ldots, \alpha - 1 \), if there are more than two branches of \( T \) at \( v_k \), then we define \( T_k \) to be the tree obtained from \( T \) by deleting two branches except \( v_k \) where one contains \( v_{k-1} \) and the other \( v_{k+1} \); if there are exactly two branches of \( T \) at \( v_k \), then we define \( T_k \) to be the tree with \( V(T_k) = \{v_k\} \). Then, \( V(T_0), \ldots, V(T_\alpha) \) are mutually disjoint sets. Moreover, for each \( k = 0, \ldots, \alpha \), we have \( e_{T_k}(v_k) \leq \alpha - k \). As an example, if \( T \) is the tree in Figure 2, then \( V(T_0) = \{v\}, \ V(T_3) = \{v_3\}, \) and \( V(T_4) = \{v_4\}; \) furthermore, \( T_1 \) and \( T_2 \) are \( S_4 \) and \( P_3 \), respectively.

Let \( Q_{T,v} = [q_{i,j}] \). Recall that \( q_{i,j} = |F_T(i,j;v)| \) is the number of 2-tree spanning forests of \( T \) having \( i, j \) in one tree and \( v \) in the other. Note that \( v = v_0 \). In order to understand the structure of \( Q_{T,v} \), we shall consider two cases: (i) \( i \) and \( j \) are in different subtrees; and (ii) \( i \) and \( j \) are in the same subtree. Suppose that \( i \in V(T_{k_1}) \) and \( j \in V(T_{k_2}) \) where \( 0 \leq k_1 < k_2 \leq \alpha \). For each forest in \( F_T(i,j;v) \), since \( i \) and \( j \) belong to the same subtree in the forest, the subtree must contain \( v_{k_1} \) and \( v_{k_2} \). For any vertex \( w \) on the subpath of \( T \) with \( i \) and \( j \) as the pendent vertices, we have \( \text{dist}_T(v,v_{k_1}) \leq \text{dist}_T(v,w) \). Hence, by Remark 3.14, \( q_{i,j} = k_1 \) for \( i \in V(T_{k_1}) \) and \( j \in V(T_{k_2}) \) with \( 0 \leq k_1 < k_2 \leq \alpha \).
Assume that $i, j$ are in $V(T_k)$ for some $1 \leq k \leq \alpha$. Consider the subpath $P'$ of $T_k$ with $i$ and $j$ as the pendent vertices. Suppose that $w_0$ is the vertex on $P'$ such that $\text{dist}_{T_k}(v_k, w_0) \leq \text{dist}_{T_k}(v_k, w)$ for $w \in V(P')$. Then, $\text{dist}_T(v, w_0) = k + \text{dist}_{T_k}(v_k, w_0)$. Let $Q_{T_k, v_0} = [\tilde{q}_{i,j}]$. By Remark 3.14, we have $q_{i,j} = k + \tilde{q}_{i,j}$.

Labelling the rows and columns of $Q_{T,v}$ in order of $v, V(T_1), \ldots, V(T_\alpha)$, we obtain the following structure:

$$
Q_{T,v} = \begin{bmatrix}
0 & 0 & 0 & \cdots & 0 \\
J + Q_{T_1,v_1} & J & J & \cdots & J \\
0 & J & 2J + Q_{T_2,v_2} & 2J & \cdots & 2J \\
0 & J & 2J & 3J + Q_{T_3,v_3} & \cdots & \vdots \\
\vdots & \vdots & \vdots & \vdots & \ddots & (\alpha - 1)J \\
0 & J & 2J & 3J & \cdots & \alpha J + Q_{T_\alpha,v_\alpha}
\end{bmatrix}
$$

where the $J$s in the blocks of $Q_{T,v}$ are appropriately sized. Let $n_k = |V(T_k)|$ for $k = 0, \ldots, \alpha$. Note that $n_0 = n_\alpha = 1$. Then, $Q_{T,v}$ can be recast as:

$$
Q_{T,v} = \sum_{i=0}^{\alpha-1} \begin{bmatrix} 0 & 0 \\
J_{n-(n_0+\cdots+n_i)} & 0 
\end{bmatrix} + \text{diag}(0, Q_{T_1,v_1}, \ldots, Q_{T_\alpha,v_\alpha})
= \sum_{i=0}^{\alpha-1} \begin{bmatrix} 0_{n_0+\cdots+n_i} & 1_{n-(n_0+\cdots+n_i)}^T 
1_{n-(n_0+\cdots+n_i)} & 0 
\end{bmatrix} + \text{diag}(0, Q_{T_1,v_1}, \ldots, Q_{T_\alpha,v_\alpha}),
$$

where $n = n_0 + n_1 + \cdots + n_\alpha$.

Now, we shall compute $d_T^T Q_{T,v} d_T$. Let $x^T = \begin{bmatrix} 0 & d_{T_1}^T & \cdots & d_{T_{\alpha-1}}^T & 0 \end{bmatrix}$ and $y = e_v + \sum_{j=1}^{\alpha-1} 2e_{v_j} + e_{v_\alpha}$. Then,

$$
x^T Q_{T,v} x = \sum_{i=0}^{\alpha-2} \left( d_{T_{i+1}}^T 1 + \cdots + d_{T_{\alpha-1}}^T 1 \right)^2 + \sum_{i=1}^{\alpha-1} d_{T_i}^T Q_{T,v} d_{T_i}
= 4 \sum_{i=0}^{\alpha-2} \left( \sum_{j=i+1}^{\alpha-1} (n_j - 1) \right)^2 + \sum_{i=1}^{\alpha-1} d_{T_i}^T Q_{T,v} d_{T_i}
= 4 \sum_{i=0}^{\alpha-2} \left( \sum_{j=i+1}^{\alpha-1} (n_j - 1) \right)^2 + \sum_{i=1}^{\alpha-1} \left( \sum_{j=i}^{\alpha} (n_j - 1) \right)^2 + \sum_{i=1}^{\alpha-1} d_{T_i}^T Q_{T,v} d_{T_i}.
$$

We can find that the submatrix of $Q_{T,v}$ whose rows and columns are indexed by $\{v_0, \ldots, v_\alpha\}$ is $\{\min(i,j)\}_{0 \leq i,j \leq \alpha}$. So, $(\sum_{k=0}^{\alpha} e_{v_k})^T Q_{T,v} (\sum_{k=0}^{\alpha} e_{v_k})$ is the sum of all entries in $\{\min(i,j)\}_{0 \leq i,j \leq \alpha}$. Thus, from $y = 2(\sum_{k=0}^{\alpha} e_{v_k}) - (e_v + e_\alpha)$, we have

$$
y^T Q_{T,v} y = 41^T \{\min(i,j)\}_{0 \leq i,j \leq \alpha} - 4(e_v + e_\alpha)^T Q_{T,v} \left( \sum_{k=0}^{\alpha} e_{v_k} \right) + (e_v + e_\alpha)^T Q_{T,v} (e_v + e_\alpha)
= \frac{2}{3} \alpha(\alpha + 1)(2\alpha + 1) - 2\alpha(\alpha + 1) + \alpha = \frac{1}{3} \alpha(2\alpha - 1)(2\alpha + 1).
$$
Finally, we find
\[
\sum_{i=0}^{\alpha-1} x^T \begin{bmatrix} 0 & 0 \\ J_{n-(n_0+\cdots+n_\alpha)} & 0 \end{bmatrix} y \\
= \sum_{i=0}^{\alpha-2} \left( d_{T_{n+i+1}}^T 1 + \cdots + d_{T_{n-i}}^T 1 \right) (2(\alpha - i) - 1) \\
= 2 \sum_{i=0}^{\alpha-2} \left( \sum_{j=i}^{\alpha-1} (n_j - 1) \right) (2(\alpha - i) - 1) = 2 \sum_{i=1}^{\alpha-1} \left( \sum_{j=i}^{\alpha-1} (n_j - 1) \right) (2(\alpha - i) + 1).
\]

From Remark 3.14, for each \(k = 0, \ldots, \alpha\), we have \(|F_{T_k}(l, v_k)| = 0\) for \(l \in V(T_k)\). So, the \(v^th\) column of \(\text{diag}(0, Q_{T_1}, \ldots, Q_{T_\alpha}, v_\alpha)\) is the zero vector. This implies \(x^T \text{diag}(0, Q_{T_1}, \ldots, Q_{T_\alpha}, v_\alpha)y = 0\). Hence,
\[
2x^T Q_{T_v, x} y = 4 \sum_{i=1}^{\alpha-1} \left( \sum_{j=i}^{\alpha-1} (n_j - 1) \right) (2(\alpha - i) + 1).
\]

Note that \(d_T = x + y\). Therefore, for a tree \(T\) with a pendant vertex \(v\),
\[
d_{T}^T Q_{T,v} d_{T} = x^T Q_{T,v} x + 2x^T Q_{T,v} y + y^T Q_{T,v} y = 4 \sum_{i=1}^{\alpha-1} \left( \sum_{j=i}^{\alpha-1} (n_j - 1) \right) + \frac{1}{3} \alpha(2\alpha - 1)(2\alpha + 1).
\]

**Example 5.1.** Let \(n \geq \alpha \geq 1\), and \(B_{n,\alpha}\) be the broom with vertices \(v, v_1, \ldots, v_\alpha\) in Figure 3. Let \(v_0 = v\), and \(X = \{0, \ldots, \alpha\}\). Suppose that for \(i \in X\), \(T_i\) is the tree with \(V(T_i) = \{v_i\}\), and \(T_{\alpha-1}\) is the subtree induced by \(V(B_{n,\alpha})\). Then, \(T_{\alpha-1}\) is a star of order \(n - \alpha\) with the centre vertex \(v_{\alpha-1}\). Let \(n_i = |V(T_i)|\) for \(i = 0, \ldots, \alpha\). By (5.11) and Example 3.19, we obtain
\[
d_{B_{n,\alpha}}^T Q_{B_{n,\alpha}, v} d_{B_{n,\alpha}, v} = 4 \sum_{i=1}^{\alpha-1} \left( n - \alpha - 1 \right)^2 + d_{S_{n-\alpha}}^T Q_{S_{n-\alpha}, v_{\alpha-1}} d_{S_{n-\alpha}} \\
+ 4 \sum_{i=1}^{\alpha-1} \left( n - \alpha - 1 \right)(2(\alpha - i) + 1) + \frac{1}{3} \alpha(2\alpha - 1)(2\alpha + 1) \\
= 4(\alpha - 1)(n - \alpha - 1)^2 + (n - \alpha)(4\alpha^2 - 3) + \frac{1}{3} \alpha(2\alpha - 1)(2\alpha + 1).
\]

**Figure 3.** A broom on \(n\) vertices with exactly \((n - \alpha)\) pendent vertices having a common neighbour.
We continue (5.11) with the same hypotheses and notation. We consider $d_{T_i}^T Q_{T_i,v_i} d_{T_i}$ for $i = 1, \ldots, \alpha - 1$ in (5.11). Note that for $i = 1, \ldots, \alpha - 1, v_i$ is not necessarily a pendent vertex in $T_i$. The result for the minimum of $d_{T_i}^T Q_{T_i,v_i} d_{T_i}$ appears in the paper [13] as the minimum of $d_{T_i}^T (2F_i 1^T - F_i) d_{T_i}$. We shall introduce the result, which is proved by induction in [13], with a different proof by using the combinatorial interpretation for entries in $Q_{T_i,v_i}$.

**Lemma 5.2 ([13]).** Let $T$ be a tree of order $n \geq 2$ with a vertex $v$. Then,

$$d_{T,v}^T d_{T,v} \geq n - 1,$$

with equality if and only if for $n = 2$, $T = P_2$ and for $n \geq 3$, $T = S_n$ and $v$ is the centre vertex.

**Proof.** Let $Q_{T,v} = [q_{i,j}]$. By Remark 3.14, we have $q_{i,j} = \text{dist}(i,v) \geq 1$ whenever $i \neq v$. The degree of each vertex is at least 1. So, we have $d_{T,v}^T d_{T,v} \geq (n - 1)$. To attain the equality, $q_{i,j} = 0$ if $i \neq j$. From Remark 3.14, we can find that $v$ is a cut-vertex so that $T - v$ consists of $n - 1$ isolated vertices. Therefore, our desired result is obtained.

Applying Lemma 5.2 to $d_{T_i}^T Q_{T_i,v_i} d_{T_i}$ in (5.11) for each $i = 1, \ldots, \alpha - 1$, we obtain $\sum_{i=1}^{\alpha-1} d_{T_i}^T Q_{T_i,v_i} d_{T_i} \geq n - \alpha - 1$. Thus, $d_{T}^T Q_{T,v} d_{T}$ in (5.11) is bounded below as follows:

$$d_{T}^T Q_{T,v} d_{T} \geq 4 \sum_{i=1}^{\alpha-1} \left( \sum_{j=i}^{\alpha-1} (n_j - 1) \right)^2 + 4 \sum_{i=1}^{\alpha-1} \left( \sum_{j=i}^{\alpha-1} (n_j - 1) \right) (2(\alpha - i) + 1) + (n - \alpha - 1) + \frac{1}{3} \alpha(2\alpha - 1)(2\alpha + 1).$$

Consider

$$(5.12) \quad \sum_{i=1}^{\alpha-1} \left( \sum_{j=i}^{\alpha-1} (n_j - 1) \right)^2 + \sum_{i=1}^{\alpha-1} \left( \sum_{j=i}^{\alpha-1} (n_j - 1) \right) (2(\alpha - i) + 1) = \left[ (n_1 + \cdots + n_{\alpha-1} - (\alpha - 1))^2 + (n_1 + \cdots + n_{\alpha-1} - (\alpha - 1))(2\alpha - 1) \right] + \left[ (n_2 + \cdots + n_{\alpha-1} - (\alpha - 2))^2 + (n_2 + \cdots + n_{\alpha-1} - (\alpha - 2))(2\alpha - 3) \right] + \cdots + \left[ (n_{\alpha-1} - (\alpha - 1))^2 + (n_{\alpha-1} - 1) \right].$$

Since $n_1 + \cdots + n_{\alpha-1}$ is constant, we find that the minimum of (5.12) is attained as $(n - \alpha - 1)(n + \alpha - 2)$ at $n_1 = n - \alpha$ and $n_2 = \cdots = n_{\alpha-1} = 1$. Therefore, when $v$ is a pendent vertex, we have

$$(5.13) \quad d_{T}^T Q_{T,v} d_{T} \geq (n - \alpha - 1)(4n + 4\alpha - 7) + \frac{1}{3} \alpha(2\alpha - 1)(2\alpha + 1),$$

where equality holds if and only if $T$ is a broom $B_{n,\alpha}$ with $v, v_1, \ldots, v_\alpha$ described below:

```
    ----
   |     |
  v ------ v_1 ------ v_2 ------ v_{\alpha-1} ---- v_\alpha
```

**Step 2.** The following is the result for the minimum of $d_{T}^T Q_{T,v} d_{T}$ where $T$ is a tree with a vertex $v$. (The vertex $v$ is not necessarily a pendent vertex.)
Note that $\beta$ paradoxical. Since $\alpha$ If $G$ i $j$ that $w(\alpha T \ell $ and $T$ Theta notation, respectively (see [1]).

Volume 38, pp. 9-31, January 2022. A publication of the International Linear Algebra Society

Electronic Journal of Linear Algebra, ISSN 1081-3810

vertex in $v,w$. Let $e$ {k $\neq$ $1$ to form $1$ Example $5.4$. If $G$ the main result in this section. We define $\alpha_n(v)$ and $\ell_n(v)$ only for the specified vertex $v$ of the trees in the sequence, so we simply write $\alpha_n(v)$ and $\ell_n(v)$ as $\alpha_n$ and $\ell_n$.

Define $B_1^{(1)} = T_1$ and $\ell_1 = 1$. Assume that for $n \geq 2$, $B_1^{(n-1)}, \ldots, B_{\ell_{n-1}}^{(n-1)}$ are the branches of $T_{n-1}$ at $v$. Let $\{w\} = V(T_n) \setminus V(T_{n-1})$. Consider the case $\ell_n - \ell_{n-1} = 1$. Then, $w$ must be added to the vertex $v$ in $T_{n-1}$ to form $T_n$. For this case, we define $B_i^{(n)}$ as $B_i^{(n-1)}$ for $i = 1, \ldots, \ell_n - 1$, and define $B_{\ell_n}^{(n)}$ as the path $(v,w)$. Suppose $\ell_n = \ell_{n-1}$. Then, there exists exactly one branch $B_k^{(n-1)}$ for some $k \in \{1, \ldots, \ell_{n-1}\}$ such that $w$ is adjacent to at least a vertex of $B_k^{(n-1)}$ in $T_n$. We define $B_i^{(n)}$ as $B_i^{(n-1)}$ for $1 \leq i \leq \ell_{n-1}$ with $i \neq k$, and define $B_{\ell_n}^{(n)}$ as the induced subtree of $T_n$ by $V(B_k^{(n-1)}) \cup \{w\}$. Hence, we may define

$$\beta_n = |\{i|e_{B_i^{(n)}}(v) = \Theta(\alpha_k), i = 1, \ldots, \ell_n\}|.$$  

Note that $\beta_n$ is the number of branches of $T_n$ at $v$ such that the eccentricity of $v$ in a branch is asymptotically bounded above and below by the eccentricity of $v$ in $T_k$.

Example 5.4. If $G^v$ is the sequence of $G^v$ where $v$ is a pendent vertex for $n \geq 2$, then $\alpha_n = n - 1$ and $\ell_n = \beta_n = 1$. If $G^v$ is the sequence of $G^v$ where $v$ is the centre vertex for $n \geq 3$, then $\alpha_n = 1$ and $\ell_n = \beta_n = n - 1$.

Remark 5.5. Consider a sequence $G^v$ of $G^v$ of trees. Evidently, $\beta_n \leq \ell_n = \mathcal{O}(n)$ and $\alpha_n = \mathcal{O}(n)$. Since $\alpha_n = \max\{|e_{B_i^{(n)}}(v)|1 \leq i \leq \ell_n\}$, we have $\beta_n \geq 1$.

Here is the main result in this section.

Theorem 5.6. Let $G^v$ be a sequence of trees. If $\beta_n\alpha_n^3 = \omega(n^2)$, then $G^v$ is asymptotically paradoxical.

Proof. Suppose that $\beta_n\alpha_n^3 = \omega(n^2)$. For $n \geq 2$, suppose that $B_i^{(1)}, \ldots, B_i^{(n)}$ are the branches of $T_n$ at $v$. Let $e_i^{(n)} = e_{B_i^{(n)}}(v)$ and $k_i^{(n)} = |V(B_i^{(n)})|$ for $i = 1, \ldots, \ell_n$. We may assume that $e_j^{(n)} = \Theta(\alpha_n)$ for $j = 1, \ldots, \beta_n$. Then, for each $j = 1, \ldots, \beta_n$, there exist $C_j > 0$ and $N_j > 0$ such that $e_j^{(n)} \geq C_j\alpha_n$ for all
Let $P$ be a longest path in $T_n$. Suppose that $w_0$ is the vertex on $P$ such that $\text{dist}(v, w_0) \leq \text{dist}(v, w)$ for all vertices $w$ on $P$. Then, $\alpha_n \geq \text{dist}(v, w_0) + \frac{1}{2}\text{diam}(T_n)$. By Corollary 5.7, our desired result follows.

A rooted tree is a tree with a vertex designated as the root such that every edge is directed away from the root. A leaf in a rooted tree is a vertex whose degree is 1. The depth of a vertex $v$ in a rooted tree is the distance between $v$ and the root. The height of a rooted tree is the maximum distance from the root to all leaves.

**Example 5.9.** Let $G^v = (T_n)^v$ be a sequence of trees. For each $n \geq 1$, $T_n$ can be considered as a rooted tree at $v$. We may also regard branches $B_1^{(n)}, \ldots, B_{\beta_v}^{(n)}$ of $T_n$ at $v$ as rooted trees at $v$. For each $n \geq 3$, let $T_n$ be obtained from $T_{n-1}$ as follows: if $e_{B_{\beta_v}^{(n-1)}}(v) = |n^\alpha| - 1$, then a new vertex $x$ is added to a leaf $z$ of $B_1^{(n-1)}$ such that the depth of $z$ is the height of $B_1^{(n-1)}$; if $e_{B_{\beta_v}^{(n-1)}}(v) = [n^\alpha]$, then a new vertex $x$ is added to a vertex $w$ in $T_{n-1}$ such that $\text{dist}(v, w) < e_{B_{\beta_v}^{(n-1)}}(v)$. Assume that $\alpha_0 = 0.7$. Considering $|3^\alpha| = |4^\alpha| = 2$ and $|5^\alpha| = |6^\alpha| = 3$, one of all possible sequences can be obtained as in Figure 4. Note that the very left branch of each rooted tree at $v$ in that figure is $B_1^{(n)}$ for $n = 2, \ldots, 6$. Then, $e_{B_1^{(n)}}(v) \geq e_{B_1^{(n)}}(v)$ for all $v$.
Families of graphs with twin pendent paths and the Braess edge

\[ n \geq 2 \text{ and } 2 \leq k \leq \ell_n. \] Moreover, \( e_{B(v)}(\omega) \geq n^\omega - 1 \) for all \( n \geq 2. \) By Corollary 5.7, \( G'' \) is asymptotically paradoxical—that is, for integers \( k_1, k_2 \geq 0 \) with \( k_1 + k_2 \geq 2, \) \( T_n \) is \((v, k_1, k_2)-\text{paradoxical for sufficiently large } n.\)

From the following example, the converses of Theorem 5.6, Corollaries 5.7 and 5.8 do not hold.

**Example 5.10.** Consider a sequence \( G'' = (T_n)^n \) where for \( n \geq 4, T_n \) is a broom \( B_{n, \alpha_n} \) with \( \alpha_n \geq 3. \)

Suppose that for each \( n \geq 4, v \) is the pendent vertex of \( B_{n, \alpha_n} \) that does not have any common neighbour with other pendent vertices in \( B_{n, \alpha_n}. \) Clearly, \( \beta_n = 1. \) Suppose that \( \alpha_n = \omega(1) \) By Example 5.1, we obtain

\[
\frac{\phi_{B_{n, \alpha_n}}(v)}{4m_{B_{n, \alpha_n}}^2 T_{n, \alpha_n}} = \frac{4(\alpha_n - 1)(n - \alpha_n - 1)^2 + (n - \alpha_n - 1)(4\alpha_n^2 - 3) + \frac{1}{4}\alpha_n(2\alpha_n - 1)(2\alpha_n + 1)}{2(n - 1)^2}
\]

\[
\geq \frac{2(\alpha_n - 1)(n - \alpha_n - 1)^2}{(n - 1)^2},
\]

for \( n \geq 4. \) Since \( n^2\alpha_n = \omega(n^2), \) we have \( \frac{\phi_{B_{n, \alpha_n}}(v)}{4m_{B_{n, \alpha_n}}^2 T_{n, \alpha_n}} \to \infty \) as \( n \) goes to infinity. Therefore, \( G'' \) is asymptotically paradoxical. Moreover, we have \( \beta_n \alpha_n^3 = \omega(1). \)

**Acknowledgement.** The author is grateful to Lorenzo Ciardo at the University of Oslo for discussions that initiated this study, and Steve Kirkland at the University of Manitoba for his encouragement, reviews, and comments.

**Post-acknowledgement.** The author acknowledges Theorem 2.1 in the article ‘arXiv:2108.01061’ in that it is equivalent to Proposition 3.1.
