Reconstructing fine details of small objects by using plasmonic spectroscopic data. Part II: The strong interaction regime

Habib Ammari*  Matias Ruiz†  Sanghyeon Yu †  Hai Zhang‡

Abstract

This paper is concerned with the inverse problem of reconstructing a small object from far field measurements by using the field interaction with a plasmonic particle which can be viewed as a passive sensor. It is a follow-up of the work [H. Ammari et al., Reconstructing fine details of small objects by using plasmonic spectroscopic data, SIAM J. Imag. Sci., 11 (2018), 1–23], where the intermediate interaction regime was considered. In that regime, it was shown that the presence of the target object induces small shifts to the resonant frequencies of the plasmonic particle. These shifts, which can be determined from the far field data, encodes the contracted generalized polarization tensors of the target object, from which one can perform reconstruction beyond the usual resolution limit. The main argument is based on perturbation theory. However, the same argument is no longer applicable in the strong interaction regime as considered in this paper due to the large shift induced by strong field interaction between the particles. We develop a novel technique based on conformal mapping theory to overcome this difficulty. The key is to design a conformal mapping which transforms the two particle system into a shell-core structure, in which the inner dielectric core corresponds to the target object. We show that a perturbation argument can be used to analyze the shift in the resonant frequencies due to the presence of the inner dielectric core. This shift also encodes information of the contracted polarization tensors of the core, from which one can reconstruct its shape, and hence the target object. Our theoretical findings are supplemented by a variety of numerical results based on an efficient optimal control algorithm. The results of this paper make the mathematical foundation for plasmonic sensing complete.

Mathematics Subject Classification (MSC2000): 35R30, 35C20.

Keywords: plasmonic sensing, superresolution, far-field measurement, generalized polarization tensors.

1 Introduction

The inverse problem of reconstructing fine details of small objects by using far-field measurements is severely ill-posed. There are two fundamental reasons for this: the diffraction limit and the low signal to noise ratio in the measurements.

Motivated by plasmonic sensing in molecular biology (see [17] and the references therein), we developed a new methodology to overcome the ill-posedness of this inverse problem in [11]. The key idea is to use a plasmonic particle to interact with the target object and to propagate its near field information into far-field in terms of the shifts in the plasmonic resonant frequencies. This plasmonic particle can be viewed as a passive sensor in the simplest form. For such a plasmonic-particle sensor, one of the most important characterization is the plasmon resonant frequencies associated with it. These resonant frequencies depend not only on the electromagnetic properties of the particle and its size and shape [8, 10, 27, 36], but also on the electromagnetic properties of the environment [8, 27, 28]. It is the last property which enables the sensing application of plasmonic particles.

In [11], the target object is modeled by a dielectric particle whose size is much smaller than that of the sensing plasmonic particle. The intermediate regime where the distance of the two particles is comparable to the size of the plasmonic particle was investigated. It was shown that the shifts of the plasmonic resonant frequencies of the plasmonic particle is small and a perturbation argument can be used to derive their asymptotic. Based on these asymptotic formulas, one can obtain their explicit dependence on the generalized polarization tensors of the target particle from which one can perform its reconstruction. However, when the distance between the particles decreases, their interactions increases and the induced shifts increase in magnitude as well. The perturbation argument will cease to work at certain threshold distance, and the characterization for the shifts of resonant frequencies in terms of information of the target particle becomes more complicated.

In this paper, we aim to extend the above investigation to the strong interaction regime where the distance of between the two particles is comparable to the size of the small particle. In this regime, the near field interactions are strong and the induced large shifts in plasmonic resonant frequencies cannot be analyzed by a perturbation argument. In order to overcome this difficulty, we develop a novel technique based on conforming mapping theory. The key is to design a conformal mapping which transforms the two-particle system into a shell-core structure, in which the inner dielectric core corresponds to the target object. We showed that a perturbation argument can be used to analyze the shift in the resonance frequencies due to the presence of the inner dielectric core. This shift also encodes information on the contracted polarization tensors of the core, from which one can reconstruct its shape, and hence the target object. The results of this paper make the mathematical foundation for plasmonic sensing complete.

The conformal mapping technique has been applied to analyze singular plasmonic systems [32, 33]. The nearly touching or touching plasmonic particles system exhibit strong field enhancements and shift of the resonances. The inversion mapping which is conformal was used to transform two circular disks or spheres into more symmetric systems [19, 34, 39]. After the transformation, the problems become easier to solve. We also refer to [21] for the fundamental limits of the field enhancements. For the general-shaped plasmonic particles, the strong shift of the plasmonic resonances was analyzed in [18].

We remark that the above idea of plasmonic sensing is closely related to that of super-resolution in resonant media, where the basic idea is to propagate the near field information into the far field through certain near field coupling with subwavelength resonators. In a recent series of papers [12, 13, 14], we have shown mathematically how to realize this idea by using weakly coupled subwavelength resonators and achieve super-resolution and super-focusing. The key is that the near field information of sources can be encoded in the subwavelength resonant
modes of the system of resonators through the near field coupling. These excited resonant modes can propagate into the far-field and thus makes the super-resolution from far field measurements possible.

This paper is organized as follows. In Section 2, we provide basic results on layer potentials and then explain the concept of plasmonic resonances and the (contracted) generalized polarization tensors. In Section 3, we consider the forward scattering problem of the incident field interaction with a system composed of a dielectric particle and a plasmonic particle. We derive the asymptotic of the scattered field in the case of strong regime. In Section 4, we consider the inverse problem of reconstructing the geometry of the dielectric particle. This is done by constructing the contracted generalized polarization tensors of the target particle through the resonance shifts induced to the plasmonic particle. We provide numerical examples to justify our theoretical results and to illustrate the performances of the proposed optimal control reconstruction scheme.

2 Preliminaries

2.1 Layer potentials

We denote by $G(x,y)$ the fundamental solution to the Laplacian in the free space $\mathbb{R}^2$, i.e.,

$$G(x,y) = \frac{1}{2\pi} \log |x-y|.$$ 

Let $D$ be a domain $\mathbb{R}^2$ with $C^{1,\eta}$ boundary for some $\eta > 0$, and let $\nu(x)$ be the outward normal for $x \in \partial D$.

We define the single layer potential $S_D$ by

$$S_D[\varphi](x) = \int_{\partial D} G(x,y) \varphi(y) d\sigma(y), \quad x \in \mathbb{R}^2,$$

and the Neumann-Poincaré (NP) operator $\mathcal{K}_D^*$ by:

$$\mathcal{K}_D^*[\varphi](x) = \int_{\partial D} \frac{\partial G}{\partial \nu(x)}(x,y) \varphi(y) d\sigma(y), \quad x \in \partial D.$$ 

The following jump relations hold:

$$S_D[\varphi]|_+ = S_D[\varphi]|_-,$$ 

$$\frac{\partial S_D[\varphi]}{\partial \nu}|_+ = \left( \pm \frac{1}{2} I + \mathcal{K}_D^* \right)[\varphi].$$ (2.1) (2.2)

Here, the subscripts $+$ and $-$ indicate the limits from outside and inside $D$, respectively.

Let $H^{1/2}(\partial D)$ be the usual Sobolev space and let $H^{-1/2}(\partial D)$ be its dual space with respect to the duality pairing $(\cdot, \cdot)^{\frac{1}{2} - \frac{1}{2}}$. We denote by $H_0^{1/2}(\partial D)$ the collection of all $\varphi \in H^{1/2}(\partial D)$ such that $(\varphi, 1)^{\frac{1}{2} - \frac{1}{2}} = 0$.

The NP operator is bounded from $H^{-1/2}(\partial D)$ to $H^{-1/2}(\partial D)$. Moreover, the operator $\lambda I - \mathcal{K}_D^*: L^2(\partial D) \to L^2(\partial D)$ is invertible for any $|\lambda| > 1/2$. Although the NP operator is not self-
adjoint on $L^2(\partial D)$, it can be symmetrized on $H^{-1/2}(\partial D)$ with a proper inner product $[15, 8]$. In fact, let $H^*(\partial D)$ be the space $H^{-1/2}(\partial D)$ equipped with the inner product $(\cdot, \cdot)_{H^*(\partial D)}$ defined by

$$(\varphi, \psi)_{H^*(\partial D)} = -(\varphi, S_D[\psi])_{\frac{1}{2}, \frac{1}{2}},$$

for $\varphi, \psi \in H^{-1/2}(\partial D)$. Then using the Plemelj’s symmetrization principle,

$$S_D K^*_D = K_D S_D,$$

it can be shown that the NP operator $K^*_D$ is self-adjoint in $H^*$ with the inner product $(\cdot, \cdot)_{H^*(\partial D)}$. It is also known that $K^*_D$ is compact when the boundary $\partial D$ is $C^{1,\eta}$ [15]. So it admits the following spectral decomposition in $H^*$

$$K^*_D = \sum_{j=1}^{\infty} \lambda_j (\varphi_j)_{H^*},$$

where $\lambda_j$ are the eigenvalues of $K^*_D$ and $\varphi_j$ are their associated eigenfunctions. Note that the eigenvalues $|\lambda_j| < 1/2$ for all $j \geq 1$.

2.2 Electromagnetic scattering in the quasi-static approximation

Let us consider a particle $D$ embedded in the free space $\mathbb{R}^2$. Equivalently, the particle $D$ in $\mathbb{R}^3$ has a translational symmetry in the direction of $z$-axis. Let $\epsilon_D$ (and $\epsilon_m$) be the permittivity of the particle $D$ (and the background), respectively. So the permittivity distribution $\epsilon$ is given by

$$\epsilon = \epsilon_D \chi(D) + \epsilon_m \chi(\mathbb{R}^2 \setminus D),$$

where and $\chi(D)$ is the characteristic function of $D$. We are interested in the scattering of the electromagnetic fields $(\mathcal{E}, \mathcal{H})$ by the particle $D$.

We assume the particle $D$ is small compared to the wavelength of the incident wave. Then we can adopt the quasi-static approximation and the electromagnetic scattering can be described by a scalar function $u$ which is called the electric potential. In the vicinity of the particle $D$, the electric field $E$ is approximated as

$$E \approx -\nabla u$$

and the electric potential $u$ satisfies:

$$\begin{cases}
\nabla \cdot (\epsilon \nabla u) = 0 & \text{in } \mathbb{R}^2, \\
u - u^i = O(|x|^{-1}) & \text{as } |x| \to \infty,
\end{cases}$$

(2.4)

where $u^i$ is the electric potential of a given incident field and satisfies $\Delta u^i = 0$ in $\mathbb{R}^2$.

The electric potential $u$ can be represented as (see, for example, [15])

$$u = u^i + S_D[\varphi],$$

(2.5)
where the density $\varphi$ satisfies the boundary integral equation
\[
(\lambda I - K_D^*)[\varphi] = \left. \frac{\partial u^i}{\partial \nu} \right|_{\partial D}.
\] (2.6)
Here, $\lambda$ is given by
\[
\lambda = \frac{\varepsilon_D + \varepsilon_m}{2(\varepsilon_D - \varepsilon_m)}.
\] (2.7)

2.3 Contracted generalized polarization tensors

In this subsection, we review the concept of the generalized polarization tensors (GPTs). It is known that the scattered field $u - u^i$ has the following asymptotic expansion in the far-field \[4, p. 77\]:
\[
(u - u^i)(x) = \sum_{|\alpha|,|\beta|\leq 1} \frac{1}{\alpha!\beta!} \partial^\alpha u^i(0) M_{\alpha\beta}(\lambda, D) \partial^\beta G(x), \quad |x| \to +\infty,
\] (2.8)
where $M_{\alpha\beta}(\lambda, D)$ is given by
\[
M_{\alpha\beta}(\lambda, D) := \int_{\partial D} y^\beta (\lambda I - K_D^*)^{-1} \left[ \frac{\partial x^\alpha}{\partial \nu} \right](y) d\sigma(y), \quad \alpha, \beta \in \mathbb{N}^2.
\]
Here, the coefficient $M_{\alpha\beta}(\lambda, D)$ is called the generalized polarization tensor \[4\].

Next we consider the simplified version of the GPTs. For a positive integer $m$, let $P_m(x)$ be the complex-valued polynomial
\[
P_m(x) = (x_1 + ix_2)^m = r^m \cos m \theta + ir^m \sin m \theta,
\] (2.9)
where we have used the polar coordinates $x = re^{i\theta}$.

We define the contracted generalized polarization tensors (CGPTs) to be the following linear combinations of generalized polarization tensors using the polynomials in (2.9):
\[
\begin{align*}
M_{cc}^{m,n}(\lambda, D) &= \int_{\partial D} \text{Re}\{P_n\}(\lambda I - K_D^*)^{-1} \left[ \frac{\partial \text{Re}\{P_m\}}{\partial \nu} \right] d\sigma, \\
M_{cs}^{m,n}(\lambda, D) &= \int_{\partial D} \text{Im}\{P_n\}(\lambda I - K_D^*)^{-1} \left[ \frac{\partial \text{Re}\{P_m\}}{\partial \nu} \right] d\sigma, \\
M_{sc}^{m,n}(\lambda, D) &= \int_{\partial D} \text{Re}\{P_n\}(\lambda I - K_D^*)^{-1} \left[ \frac{\partial \text{Im}\{P_m\}}{\partial \nu} \right] d\sigma, \\
M_{ss}^{m,n}(\lambda, D) &= \int_{\partial D} \text{Im}\{P_n\}(\lambda I - K_D^*)^{-1} \left[ \frac{\partial \text{Im}\{P_m\}}{\partial \nu} \right] d\sigma.
\end{align*}
\] (2.10)

We remark that CGPTs defined above encodes useful information about the shape of the particle $D$ and can be used for its reconstruction. See \[4, 3, 5, 6\] for more details.

For convenience, we introduce the following notation. We denote
\[
M_{m,n}(\lambda, D) = \begin{pmatrix}
M_{cc}^{m,n}(\lambda, D) & M_{cs}^{m,n}(\lambda, D) \\
M_{sc}^{m,n}(\lambda, D) & M_{ss}^{m,n}(\lambda, D)
\end{pmatrix}.
\]
It is worth mentioning that the following symmetry holds (see \[4\]):
\[
M_{m,n} = M_{m,n}^T.
\]

When $m = n = 1$, the matrix $M(\lambda, D) := M_{1,1}(\lambda, D)$ is called the first order polarization
Specifically, we have

\[ M(\lambda, D)_{lm} = \int_{\partial D} y_j (\lambda I - K_D^*)^{-1} [\nu_i](y) \, d\sigma(y), \quad l, m = 1, 2. \]

We also have from (2.8) that

\[ (u - u^i)(x) = \frac{x^T \cdot M(\lambda, D) \nabla u^i}{|x|^2} + O(|x|^{-2}), \quad \text{as } |x| \to \infty. \]

So the leading order term in the far-field expansion of the scattered field \( u - u^i \) is determined by the first order polarization tensor \( M(\lambda, D) \). The quantity \( M(\lambda, D)(-\nabla u^i) \) is called the dipole moment. In fact, the leading order term is the electric potential generated by a point dipole source with dipole moment \( M(\lambda, D)(-\nabla u^i) \).

### 2.4 Plasmonic resonances

Here we explain the plasmonic resonances. We say that the particle \( D \) is plasmonic when its permittivity \( \varepsilon_D \) has negative real parts. It is known that the permittivity of noble metals, such as gold and silver, has such a property. More precisely, the permittivity \( \varepsilon_D \) of the plasmonic (or metallic) particle \( D \) is often modeled by the following Drude’s model:

\[ \varepsilon_D = \varepsilon_D(\omega) = 1 - \frac{\omega_p^2}{\omega(\omega + i\gamma)}, \quad (2.11) \]

where \( \omega \) is the operating frequency. Here, \( \omega_p > 0 \) means the plasma frequency and \( \gamma > 0 \) means the damping parameter. Usually, the parameter \( \gamma \) is a very small number. So \( \varepsilon_D(\omega) \) also has a small imaginary part. Note that, when \( \omega < \omega_p \), the permittivity \( \varepsilon_D \) has a negative real part. Contrary to plasmonic particles, ordinary dielectric particles have positive real parts. Note that, by (2.7), \( \lambda \) becomes frequency dependent.

Now we discuss the resonant behavior of the solution \( u \) when \( \varepsilon_D \) is negative (or the particle \( D \) is plasmonic). Recall that the solution \( u \) is represented as

\[ u = u^i + S_D[\varphi], \quad (2.12) \]

where the density \( \varphi \) satisfies the boundary integral equation

\[ (\lambda(\omega)I - K_D^*)[\varphi] = \frac{\partial u^i}{\partial \nu}|_{\partial D}. \quad (2.13) \]

By the spectral decomposition (2.3) of \( K_D^* \), we have from (2.6) that

\[ u = u^i + \sum_{j=1}^{\infty} \frac{\langle \frac{\partial u^i}{\partial \nu}, \varphi_j \rangle_{H^*(\partial D)} \lambda(\omega) - \lambda_j}{S_D[\varphi_j]}. \quad (2.14) \]

Recall that \( \lambda_j \) are eigenvalues of \( K_D^* \) and they satisfy the condition that \( |\lambda_j| < 1/2 \). When \( \varepsilon_D \) has negative real parts, we have \( |\text{Re}\{\lambda(\omega)\}| < 1/2 \). Let \( \omega_j \) be such that \( \lambda(\omega_j) = \lambda_j \). Then, if \( \omega \) is close to \( \omega_j \) and \( \langle \frac{\partial u^i}{\partial \nu}, \varphi_j \rangle_{H^*(\partial D)} \neq 0 \), the function \( S_D[\varphi_j] \) in (2.14) will be greatly amplified and
dominates over other terms. As a result, the magnitude of the scattered field \( u - u^i \) will show a pronounced peak at the frequency \( \omega_j \) as a function of the frequency \( \omega \). This phenomenon is called the plasmonic resonance and \( \omega_j \) is called the plasmonic resonant frequency and \( S_D[\varphi_j] \) is called the resonant mode.

Let us discuss how we can measure the resonant frequency \( \omega_j \) or the eigenvalue \( \lambda_j \) from the far field measurements. In fact, the far field for the solution \( -\nabla u \) is not equal to the true far-field of the electromagnetic wave since the quasi-static approximation is valid only in the vicinity of the particle \( D \). But, the polarization tensor \( M(\lambda, D) \), which is introduced in the quasi-static approximation, is useful when describing the far-field behavior of the true scattered field.

We first represent \( M(\lambda, D) \) in a spectral form. By (2.3), we have

\[
M(\lambda, D)_{lm} = \sum_{j=1}^{\infty} \frac{(y_m, \varphi_j) - \frac{1}{2} \frac{1}{\lambda_j} (\varphi_j, \nu_l) H^*(\partial D)}{\lambda(\omega) - \lambda_j},
\]

As discussed in Subsection 2.3, the small particle \( D \) can be considered as a point dipole source located at \( x_0 \in \mathbb{R}^2 \) and its dipole moment is given by \( p_D = M(\lambda, D)(-\nabla u^i) \). We can see from the above spectral representation that the dipole moment \( p_D \) becomes resonant when \( \omega \approx \omega_j \).

Let \( G^\omega \) be the dyadic Green’s function

\[
G^\omega(x, y) = (\omega^2 I + \nabla \cdot \nabla)G^\omega(x, y)
\]

where \( G^\omega(x, y) = -\frac{i}{4} H_0^{(1)}(\omega|x - y|) \). Then the (true) scattered electric field \( E^s \) is well approximated over the whole region as \([7, 37]\)

\[
E^s \approx G^\omega(x, x_0)p_D.
\]

So, if \( \omega \approx \omega_j \), then the amplitude of the scattered wave \( E^s \) will be greatly enhanced. So, as a function of the frequency \( \omega \), it will have local peaks from which we can recover the resonant frequency \( \omega_j \) (or the plasmonic eigenvalue \( \lambda_j \)). More specifically, we measure the so called the absorption cross section \( \sigma_a \) from the scattered field \( E^s \) at the far field region. In fact, this quantity can be approximated as \( \sigma_a \propto \text{Im}(p_D) \) for a small plasmonic particle.

### 3 The forward problem

We consider a system composed of a dielectric particle and a plasmonic particle embedded in a homogeneous medium. The target dielectric particle and the plasmonic particle occupy respectively a bounded and simply connected domain \( D_1 \subset \mathbb{R}^2 \) and \( D_2 \subset \mathbb{R}^2 \) of class \( C^{1,\alpha} \) for some \( 0 < \alpha < 1 \). We denote the permittivity of the dielectric particle \( D_1 \) and the plasmonic particle \( D_2 \) by \( \varepsilon_1 \) and \( \varepsilon_2 \), respectively. As before, the permittivity of the background medium is denoted by \( \varepsilon_m \). So the permittivity distribution \( \varepsilon \) is given by

\[
\varepsilon := \varepsilon_1 \chi(D_1) + \varepsilon_2 \chi(D_2) + \varepsilon_m \chi(\mathbb{R}^2 \setminus (D_1 \cup D_2)).
\]
As in Subsection 2.4, the permittivity $\varepsilon_2$ of the plasmonic particle $D_2$ depends on the operating frequency and is modeled as

$$\varepsilon_2 = \varepsilon_2(\omega) = 1 - \frac{\omega_p^2}{\omega (\omega + i\gamma)}.$$ 

The total electric potential $u$ satisfies the following equation:

$$\begin{cases}
\nabla \cdot (\varepsilon \nabla u) = 0 & \text{in } \mathbb{R}^2 \setminus (\partial D_1 \cup \partial D_2), \\
u_+ = u_- & \text{on } \partial D_1 \cup \partial D_2, \\
\frac{\varepsilon_m}{\nu} \frac{\partial u}{\partial \nu} = \frac{\varepsilon_1}{\nu} \frac{\partial u}{\partial \nu} & \text{on } \partial D_1, \\
\frac{\varepsilon_m}{\nu} \frac{\partial u}{\partial \nu} = \frac{\varepsilon_2}{\nu} \frac{\partial u}{\partial \nu} & \text{on } \partial D_2, \\
(u - u^i)(x) = O(|x|^{-1}), & \text{as } |x| \to \infty,
\end{cases} \quad (3.1)$$

where $u^i(x)$ is the electric potential for a given incident field as before.

### 3.1 Boundary integral formulation

We derive a layer potential representation of the total field $u$ to (3.1) in this section. We first denote by $u_{D_1}$ the total field resulting from the incident field $u^i$ and the ordinary particle $D_1$ (in the absence of the plasmonic particle $D_2$). Let us denote

$$\lambda_{D_j} = \frac{\varepsilon_j + \varepsilon_m}{2(\varepsilon_j - \varepsilon_m)}, \quad j = 1, 2.$$ 

Then $u_{D_1}$ has the following representation [4]:

$$u_{D_1}(x) = u^i(x) + S_{D_1} \left( \lambda_{D_1} I d - K_{D_1}^* \right)^{-1} \frac{\partial u^i}{\partial \nu_1}(x), \quad \text{for } x \in \mathbb{R}^2 \setminus \overline{D_1}.$$ 

We next introduce the Green function $G_{D_1}(\cdot, y)$ for the medium with permittivity distribution $\varepsilon_{D_1} \chi(D_1) + \varepsilon_m \chi(\mathbb{R}^2 \setminus D_1)$. More precisely, $G_{D_1}(\cdot, y)$ satisfies the following equation

$$\nabla_x \cdot ((\varepsilon_{D_1} \chi(D_1) + \varepsilon_m \chi(\mathbb{R}^2 \setminus D_1)) \nabla_x G_{D_1}(x, y)) = \delta(x - y).$$

Using $G_{D_1}$, we define the layer potential $S_{D_2, D_1}$ by

$$S_{D_2, D_1}[\varphi](x) = \int_{\partial D_2} G_{D_1}(x, y) \varphi(y) d\sigma(y).$$

We also define

$$A = K_{D_2}^* - \frac{\partial}{\partial \nu_2} S_{D_1} \left( \lambda_{D_1} I d - K_{D_1}^* \right)^{-1} \frac{\partial S_{D_2}[\cdot]}{\partial \nu_1}.$$ 

It was proved in [11] that the solution $u$ can be represented using $S_{D_2, D_1}$ and $A$ as shown in the following lemma.
Lemma 3.1. [11] The total electric potential \( u \) can be represented as follows:

\[
 u = u_{D_1} + S_{D_2,D_1}[\psi], \quad x \in \mathbb{R}^2 \setminus \overline{D_2},
\]

where the density \( \psi \) satisfies

\[
 (\lambda_{D_2} \text{Id} - \mathcal{A})[\psi] = \frac{\partial u_{D_1}}{\partial \nu_2},
\]

(3.3)

3.2 Strong interaction regime and conformal transformation

We assume the following condition on the sizes of the particles \( D_1 \) and \( D_2 \).

Condition 1. The plasmonic particle \( D_2 \) has size of order one; the dielectric particle \( D_1 \) has size of order \( \delta \ll 1 \).

Definition 3.1 (Strong interaction regime). We say that the small dielectric particle \( D_1 \) is in the strong regime with respect to the plasmonic particle \( D_2 \) if there exist positive constants \( C_1 \) and \( C_2 \) such that \( C_1 \delta \leq \text{dist}(D_1,D_2) \leq C_2 \delta \).

Definition 3.1 says that the dielectric particle \( D_1 \) is closely located to the plasmonic particle \( D_2 \) with a separation distance of order \( \delta \).

In our recent paper [11], the intermediate interaction regime is considered. The key observation is that, if we assume the distance between \( D_1 \) and \( D_2 \) is assumed to be of order one, then the effect of the small unknown particle \( D_1 \) can be considered as a small perturbation. To see this, we rewrite the equation (3.3) in the form

\[
 (A_{D_2,0} + A_{D_2,1})[\psi] = \frac{\partial u_{D_1}}{\partial \nu_2},
\]

(3.4)

where

\[
 A_{D_2,0} = \lambda_{D_2} \text{Id} - \mathcal{K}^*_{D_2},
\]

\[
 A_{D_2,1} = \frac{\partial}{\partial \nu_2} S_{D_1} \left( \lambda_{D_1} \text{Id} - \mathcal{K}^*_{D_1} \right)^{-1} \frac{\partial S_{D_2}}{\partial \nu_1}.
\]

(3.5)

It can be shown that the operator \( A_{D_2,1} \) is a small perturbation to the operator \( A_{D_2,0} \) [11], and so, the authors were able to apply the perturbation method for analyzing the plasmonic resonance. However, in the strong interaction regime, the operator \( A_{D_2,1} \) is no longer small compared to the latter. As a consequence, the perturbation theory is not applicable and it becomes challenging to analyze the interaction between the particles.

We now introduce a method to tackle this issue by using conformal mapping technique. Let \( B_1 \) be a circular disk containing the dielectric particle \( D_1 \) with radius \( r_1 \) of order \( \delta \). We assume the plasmonic particle \( D_2 \) is a circular disk with radius \( r_2 \). For convenience, we denote \( D_2 \) by \( B_2 \). We emphasize that the shape of \( D_1 \) is unknown. We let \( d \) to be the distance between the two disks \( B_1 \) and \( B_2 \), i.e.,

\[
 d = \text{dist}(B_1,B_2).
\]
By the assumption, $d$ is of order $\delta$.

Let $R_j$ be the reflection with respect to $\partial B_j$ and let $p_1$ and $p_2$ be the unique fixed points of the combined reflections $R_1 \circ R_2$ and $R_2 \circ R_1$, respectively. Let $n$ be the unit vector in the direction of $p_2 - p_1$. We set $(x, y) \in \mathbb{R}^2$ to be the Cartesian coordinates such that $p = (p_1 + p_2)/2$ is the origin and the $x$-axis is parallel to $n$. Then one can see that $p_1$ and $p_2$ can be written as

$$p_1 = (-a, 0) \quad \text{and} \quad p_2 = (a, 0),$$

where the constant $a$ is given by

$$a = \sqrt{d \sqrt{(2r_1 + d)(2r_2 + d)(2r_1 + 2r_2 + d)} / 2(r_1 + r_2 + d)}.$$  \hfill (3.7)

Then the center $c_i$ of $B_i$ ($i = 1, 2$) is given by

$$c_i = \left( (-1)^i \sqrt{r_i^2 + a^2}, 0 \right).$$

Define the conformal transformation $\Phi$ by

$$\zeta = \Phi(z) = \frac{z + a}{z - a}, \quad z = x + iy.$$  \hfill (3.8)

In other words,

$$z = \Phi^{-1}(\zeta) = a \frac{\zeta + 1}{\zeta - 1}.$$  \hfill (3.8)

We also define

$$s_j = (-1)^j \sinh^{-1}(a/r_j), \quad j = 1, 2,$$

and the two disks $\tilde{B}_1$ and $\tilde{B}_2$ by

$$\tilde{B}_1 = \{|\zeta| < \tilde{r}_j\}, \quad \tilde{r}_j = \exp(s_j), \quad j = 1, 2.$$  \hfill (3.8)

It can be shown that, in the $\zeta$-plane, the disks $B_1$ and $B_2$ are transformed to

$$\Phi(B_1) = \tilde{B}_1 = \{|\zeta| < \tilde{r}_1\},$$

and

$$\Phi(B_2) = \mathbb{R}^2 \setminus \tilde{B}_2 = \{|\zeta| > \tilde{r}_2\}.$$  \hfill (3.8)

One can check that $\tilde{r}_1 < 1$ and $\tilde{r}_2 > 1$. The exterior region $\mathbb{R}^2 \setminus \tilde{B}_1 \cup \tilde{B}_2$ becomes a shell region between $\partial \tilde{B}_1$ and $\partial \tilde{B}_2$ in the $\zeta$-plane:

$$\Phi(\mathbb{R}^2 \setminus \tilde{B}_1 \cup \tilde{B}_2) = \tilde{B}_2 \setminus \tilde{B}_1 = \{\tilde{r}_1 < |\zeta| < \tilde{r}_2\}.$$  \hfill (3.8)

To illustrate the geometry, in Figure 1, we show an example for the configuration of a system of a small dielectric particle $D_1$ and a plasmonic particle $B_2$. We also show its transformed geometry by the conformal map $\Phi$. We set $\delta = 0.2$, $r_1 = \delta$, $r_2 = 1$ and $d = \delta$.

It is worth mentioning that the shape of the transformed domain $\tilde{D}_1$ strongly depends on the ratio between $d$ and $\delta$ but is independent of $\delta$ itself. Suppose that $d = c\delta$ for some $c > 0$. If
c is of order one, then the shape of $\widetilde{D}_1$ is almost the same as that of $D_1$. On the contrary, if $c$ is too small, then the shape of $\widetilde{D}_1$ is highly distorted. See Figure 2.

3.3 Boundary integral formulation in the transformed domain

Let us define $\tilde{u}(\zeta) = u(\Phi^{-1}(\zeta))$ and $\tilde{u}^i(\zeta) = u^i(\Phi^{-1}(\zeta))$. Then, since the mapping $\Phi$ is conformal, $\tilde{u}$ and $\tilde{u}^i$ are harmonic in the $\zeta$-plane. Moreover, the transmission conditions for $\tilde{u}$ are preserved.

In fact, the transformed potential $\tilde{u}$ satisfies the following equations:

$$
\begin{align*}
\nabla \cdot (\tilde{\varepsilon} \nabla \tilde{u}) &= 0 \quad \text{in } \mathbb{R}^2 \setminus (\partial \widetilde{D}_1 \cup \partial \widetilde{D}_2), \\
\tilde{u} &= \tilde{u}^- \\
\varepsilon_m \frac{\partial \tilde{u}}{\partial \nu}^+ &= \varepsilon_1 \frac{\partial \tilde{u}}{\partial \nu}^- \quad \text{on } \partial \widetilde{D}_1, \\
\varepsilon_2 \frac{\partial \tilde{u}}{\partial \nu}^+ &= \varepsilon_m \frac{\partial \tilde{u}}{\partial \nu}^- \quad \text{on } \partial \widetilde{D}_2, \\
(\tilde{u} - \tilde{u}^i)(\zeta) &= O(|\zeta - (1,0)|) \quad \text{as } \zeta \to (1,0),
\end{align*}
$$

(3.9)

where the transformed permittivity distribution $\tilde{\varepsilon}$ is given by

$$
\tilde{\varepsilon} = \varepsilon_1 \chi(\widetilde{D}_1) + \varepsilon_2 \chi(\mathbb{R}^2 \setminus \widetilde{D}_2) + \varepsilon_m \chi(\widetilde{D}_2 \setminus \widetilde{D}_1).
$$

Note that the transformed problem looks similar to the original one, even though the geometry of the particles is of a completely different nature. As $\delta$ goes to zero, the radii $\tilde{r}_1$ and $\tilde{r}_2$ have...
the following asymptotic properties:
\[ \tilde{r}_1 = \tilde{r}_1^0 + O(\delta), \quad \tilde{r}_2 = 1 + O(\delta) \]
for some \( 0 < r_1^0 < 1 \) independent of \( \delta \). Hence, in contrast to the original problem, the transformed boundaries \( \partial \tilde{B}_1 \) and \( \partial \tilde{B}_2 \) (\( = \partial \tilde{D}_2 \)) are not close to touching. Moreover, they share the same center (see Figure 1). This will enable us to analyze more deeply the spectral nature of the problem.

Now we represent the solution to the transformed problem using the layer potentials. By applying a similar procedure as the one used for (3.5), we can obtain the following representation:
\[ \tilde{u} = (\text{const.}) + u_{\tilde{D}_1} + S_{\tilde{D}_2, \tilde{D}_1} [\tilde{\psi}], \quad x \in \mathbb{R}^2. \]
Here, the constant term is needed to satisfy the last condition in (3.9). The density function \( \tilde{\psi} \) satisfies the following boundary integral equation:
\[ (\lambda_{\tilde{D}_2} I - \tilde{A}) \tilde{\psi} = \frac{\partial \tilde{u}}{\partial \nu_2}, \]
where
\[ \tilde{A} = \kappa_{\tilde{D}_2}^* - \frac{\partial}{\partial \nu_2} S_{\tilde{D}_1} \left( \lambda_{\til\til{D}_1} I - \kappa_{\til\til{D}_1}^* \right)^{-1} \frac{\partial S_{\til\til{D}_2}}{\partial \nu_1}, \]
\[ \tilde{u}_{\til\til{D}_1} = \til\til{u} + S_{\til\til{D}_1} \left( \lambda_{\til\til{D}_1} I - \kappa_{\til\til{D}_1}^* \right)^{-1} \left[ \frac{\partial \til\til{u}}{\partial \nu_1} \right]. \]

**Lemma 3.2.** The following relation between \( A \) and \( \tilde{A} \) holds
\[ (\phi, A[\psi])_{H^*(\partial D_2)} = (\til\til{\phi}, \til\til{A}[\til\til{\psi}])_{H^*(\partial \til\til{D}_2)}, \]
where \( \phi, \psi \in H^*(\partial D_2) \) and \( \til\til{\phi} = \phi \circ \Phi^{-1}, \til\til{\psi} = \psi \circ \Phi^{-1}. \)
Proof. By the conformality of the map \( \Phi \), the single layer potentials \( S_{D_2}[\phi] \) and \( \tilde{S}_{D_2}[\tilde{\phi}] \circ \Phi \) are identical up to an additive constant, whence (3.14) follows.

3.4 Computation of the operator \( \tilde{A} \) and its spectral properties

Here we compute the operator \( \tilde{A} \). Note that \( \tilde{A} \) is an operator which maps \( H^*(\partial\tilde{D}_2) \) onto \( H^*(\partial\tilde{D}_2) \). Since \( \partial\tilde{D}_2 \) is a circle, we use the Fourier basis for \( H^*(\partial\tilde{D}_2) \). Let \((r, \theta)\) be the polar coordinates in the \( \zeta \)-plane, i.e., \( \zeta = re^{i\theta} \). We define
\[
\varphi^c_n(\theta) = \cos n\theta, \quad \varphi^s_n(\theta) = \sin n\theta.
\]

The following proposition holds.

**Proposition 3.1.** We have
\[
\tilde{A}[\varphi^c_n](\zeta) = \sum_{m=1}^{\infty} -\frac{\tilde{r}_2^{-(n+m)}}{4\pi n} (M_{cc}^{\lambda_{D_1}, \tilde{D}_1} \cos m\theta + M_{cs}^{\lambda_{D_1}, \tilde{D}_1} \sin m\theta), \quad (3.15)
\]
and
\[
\tilde{A}[\varphi^s_n](\zeta) = \sum_{m=1}^{\infty} -\frac{\tilde{r}_2^{-(n+m)}}{4\pi n} (M_{sc}^{\lambda_{D_1}, \tilde{D}_1} \cos m\theta + M_{ss}^{\lambda_{D_1}, \tilde{D}_1} \sin m\theta) \quad (3.16)
\]
for \( n \neq 0 \).

**Proof.** Since \( \partial\tilde{D}_2 \) is a circle, \( K^*_{\tilde{D}_2} = 0 \) on \( H^*(\partial\tilde{D}_2) \). Therefore, we only need to consider the second term in \( A \). It is easy to see that
\[
S_{D_2}[\varphi^c_n](r, \theta) = -\frac{\tilde{r}_2^{-(n+1)}}{2n} r^n \cos n\theta, \quad (3.17)
\]
\[
S_{D_2}[\varphi^s_n](r, \theta) = -\frac{\tilde{r}_2^{-(n+1)}}{2n} r^n \sin n\theta, \quad (3.18)
\]
for \( 0 \leq r \leq \tilde{r}_2 \). Thus, we have
\[
\tilde{A}[\varphi^c_n](\zeta) = -\frac{\tilde{r}_2^{-(n+1)}}{2n} \frac{\partial}{\partial \nu_2} \int_{\partial D_1} G(\zeta, \zeta') \left( \lambda_{D_1} I - K^*_{\tilde{D}_1} \right)^{-1} \left[ \frac{\partial}{\partial \nu_1} \text{Re}\{P_n\} \right](\zeta') d\sigma(\zeta'). \quad (3.19)
\]
It is known that [2]
\[
G(x, y) = \sum_{m=1}^{\infty} \frac{(-1)^m}{2\pi m} \frac{r_x^m}{r_x^m r_y^m} \cos(m\theta_y) + \frac{(-1)^m}{2\pi m} \frac{r_y^m}{r_x^m} \sin(m\theta_y), \quad |x| < |y|,
\]
where \((r_x, \theta_x)\) and \((r_y, \theta_y)\) are the polar coordinates of \( x \) and \( y \), respectively. Then, by letting
\( x = \zeta \) and \( y = \zeta' \in \partial \tilde{D}_2 \), we get

\[
\tilde{A}[\varphi_n^c](\zeta) = \sum_{m=1}^{\infty} -\frac{\tilde{r}^{-(n+m)}}{4\pi n} \cos m\theta \int_{\partial \tilde{D}_1} \text{Re}\{P_m\} \left( \lambda_{D_1} I - \mathcal{K}^*_{\tilde{D}_1} \right)^{-1} \left[ \frac{\partial}{\partial \nu_1} \text{Re}\{P_n\} \right] (\zeta') d\sigma(\zeta')
\]

\[
-\frac{\tilde{r}^{-(n+m)}}{4\pi n} \sin m\theta \int_{\partial \tilde{D}_1} \text{Im}\{P_m\} \left( \lambda_{D_1} I - \mathcal{K}^*_{\tilde{D}_1} \right)^{-1} \left[ \frac{\partial}{\partial \nu_1} \text{Re}\{P_n\} \right] (\zeta') d\sigma(\zeta').
\]

Finally, from the definition of the CGPTs (see (2.10)), (3.15) follows. Similarly, one can derive (3.16).

Let us define

\[
M_{nm} = M_{nm}(\lambda_{D_1}, \tilde{D}_1) = \begin{pmatrix} M_{cc}^{nm}(\lambda_{D_1}, \tilde{D}_1) & M_{cs}^{nm}(\lambda_{D_1}, \tilde{D}_1) \\ M_{sc}^{nm}(\lambda_{D_1}, \tilde{D}_1) & M_{ss}^{nm}(\lambda_{D_1}, \tilde{D}_1) \end{pmatrix},
\]

and

\[
\tilde{M}_{nm} = -\frac{\tilde{r}^{-(n+m)}}{4\pi n} M_{nm}(\lambda_{D_1}, \tilde{D}_1).
\]

In view of Proposition 3.1, we see that the operator \( \tilde{A} \) can be represented in a block matrix form as follows:

\[
\tilde{A} = \begin{bmatrix} \tilde{M}_{11} & \tilde{M}_{12} & \tilde{M}_{13} & \cdots \\ \tilde{M}_{21} & \tilde{M}_{22} & \cdots & \cdots \\ \tilde{M}_{31} & \cdots & \cdots & \cdots \\ \cdots & \cdots & \cdots & \cdots \end{bmatrix}.
\]

Recall that \( \tilde{D}_1 \) is contained in the disk \( \tilde{B}_1 \) with radius \( \tilde{r}_1 \). One can derive that

\[
|M_{nm}(\lambda_{D_1}, \tilde{D}_1)| \leq C\tilde{r}_1^{n+m}
\]

for some positive constant \( C \). Therefore,

\[
|\tilde{M}_{nm}(\lambda_{D_1}, \tilde{D}_1)| \leq C \left( \frac{\tilde{r}_1}{\tilde{r}_2} \right)^{n+m}.
\]

This decay property of \( \tilde{M}_{nm} \) is crucial for our conformal mapping technique. An important consequence is that the operator \( \tilde{A} \) can be efficiently approximated by finite dimensional matrices obtained through a standard truncation procedure. Here we remark that \( \tilde{A} = O((\tilde{r}_1/\tilde{r}_2)^2) \).

If the particle \( D_1 \) is in the strong regime, then we may write \( d = c\delta \) for some \( c > 0 \). If \( c \) is of order one, the ratio \( \frac{\tilde{r}_1}{\tilde{r}_2} \) is relatively small (but regardless of how small \( \delta \) is). In section 4 we apply the eigenvalue perturbation method to analyze the spectral nature more explicitly when we consider the related inverse problem.

### 3.5 Spectral decomposition \( A \) of and the scattered field

It is clear that \( \tilde{A} \) (or \( A \)) is compact. Moreover it can be shown that \( \tilde{A} \) is self-adjoint in \( \mathcal{H}^*(\partial \tilde{D}_2) \).
Lemma 3.3. The operator $\tilde{\mathcal{A}}$ is self-adjoint in $\mathcal{H}^*(\partial D_2)$, i.e.,

$$(\tilde{\phi}, \tilde{\mathcal{A}}[\tilde{\psi}])_{\mathcal{H}^*(\partial D_2)} = (\tilde{\psi}, \tilde{\mathcal{A}}[\tilde{\phi}])_{\mathcal{H}^*(\partial D_2)}$$

for $\tilde{\phi}, \tilde{\psi} \in \mathcal{H}^*(\partial D_2)$.

Proof. For simplicity, we consider the case when $\tilde{\phi} = \varphi^c_m$ and $\tilde{\psi} = \varphi^c_n$ only. The other cases can be done similarly. From (3.17), we have $S_{\tilde{D}_2}[\varphi^c_n]|_{\partial \tilde{D}_2} = -\frac{\tilde{r}_2}{2n} \varphi^c_n$. Then, using (3.20) and (3.21), we have

$$(\varphi^c_n, \tilde{\mathcal{A}}[\varphi^c_m])_{\mathcal{H}^*(\partial D_2)} = -\frac{1}{2} (\varphi^c_n, S_{\partial \tilde{D}_2} \tilde{\mathcal{A}}[\varphi^c_m]) = -\frac{\tilde{r}_2}{8nm} M_{nm}(\lambda_{D_1}, \tilde{D}_1).$$

So we get the conclusion.

So $\mathcal{A}$ admits the following spectral decomposition:

$$\tilde{\mathcal{A}} = \sum_{n=1}^{\infty} \lambda_j \tilde{\psi}_n \otimes \tilde{\psi}_n$$

where $\{(\lambda_n, \tilde{\psi}_n) : n \geq 1\}$ is the set of its eigenvalue-eigenfunction pairs. We order the eigenvalues in such a way that $|\lambda_j|$ is decreasing and tends to 0 as $j \to \infty$. We remark that all the eigenvalues $\{\lambda_j : j \geq 1\}$ lie in the interval $(-1/2, 1/2)$. Moreover, they can be numerically approximated by the eigenvalues of a finite truncation of the infinite matrix $\tilde{\mathcal{A}}$.

Thanks to (3.14), if we let $\psi_n = \psi_n \circ \Phi$, then we obtain

$$\mathcal{A} = \sum_{n=1}^{\infty} \lambda_j \psi_n \otimes \psi_n.$$  \hfill (3.23)

It is also worth mentioning that the orthogonality of basis $\{\psi_n\}$ is also preserved.

Using the spectral representation formula (3.23), we can derive the following result.

Theorem 3.1. Assume that Condition 4 holds and that $D_2$ is in the strong interaction regime, then the scattered field $u^s_{D_2} = u - u_{D_1}$ by the plasmonic particle $D_2$ has the following representation:

$$u^s_{D_2} = S_{D_2,D_1}[\psi],$$

where $\psi$ satisfies

$$\psi = \sum_{j=1}^{\infty} \frac{(\nabla u^i(z) \cdot \nu, \psi_j)_{\mathcal{H}^*(\partial D_2)} \psi_j + O(\delta^2)}{\lambda_{D_2} - \lambda_j}.\frac{1}{|x|^2}.\frac{\delta^3}{\text{dist}(\lambda_{D_2}, \sigma(A))}.$$}

As a corollary, we obtain the following asymptotic expansion of the scattered field $u - u^i$.

Theorem 3.2. The following far field expansion holds:

$$(u - u^i)(x) = \nabla u^i(z) \cdot M(\lambda_{D_1}, \lambda_{D_2}, D_1, D_2) \nabla G(x, z) + O \left( \frac{\delta^3}{\text{dist}(\lambda_{D_2}, \sigma(A))|x|^2} \right).$$
as $|x| \to \infty$. Here, $z$ is the center of mass of $D_2$ and $M(\lambda_{D_1}, \lambda_{D_2}, D_1, D_2)$ is the polarization tensor satisfying

$$M(\lambda_{D_1}, \lambda_{D_2}, D_1, D_2)_{l,m} = \sum_{j=1}^{\infty} \frac{(\nu_l, \psi_j)_{\mathcal{H}^*(\partial D_2)}(\psi_j, x_m) - \frac{1}{2} \frac{1}{2} + O(\delta^2)}{\lambda_{D_2} - \lambda_j}$$

for $l, m = 1, 2$.

We can introduce the resonant frequency $\omega_j$ for the system of two particles $D_1 \cup D_2$ as in Subsection 2.4. From the above far field expansion of the scattered field, it is clear that when we vary the frequency $\omega$, at certain frequency $\omega$ such that $\lambda_{D_2}(\omega) \approx \lambda_j$ for some $j$ which satisfies the condition that

$$(\nu_l, \psi_j)_{\mathcal{H}^*(\partial D_2)}(\psi_j, x_m) - \frac{1}{2} \frac{1}{2} \neq 0,$$

the scattered field will show a sharp peak, which corresponds to the excitation of a plasmonic resonance. Such a frequency is called the (plasmonic) resonant frequency for the system of two particles, which is different from the one for the single plasmonic particle $D_2$. The difference is called the shift of resonant frequency. This shift is due to the interaction of the target particle with the plasmonic particle. As discussed in Subsection 2.4, the resonant frequencies $\omega_j$ of the two-particle system can also be measured from the far field. They also determines $\lambda_j$ which are eigenvalues of the operator $A$. In the next section, we discuss how to reconstruct the shape of $D_1$ from these recovered eigenvalues.

## 4 The inverse problem

In this section, we discuss the inverse problem to reconstruct the shape of the small unknown particle $D_1$ by using the resonances of the plasmonic particle $D_2$ which interacts with $D_1$. We assume the location of $D_1$ and the permittivity $\epsilon_1$ are known for simplicity. As explained in the previous section, we can measure the eigenvalues $\lambda_j$ for $j = 1, 2, \ldots, J$, from the far-field measurements. Since the single set of the measurement data is not enough for the reconstruction, we shall make measurements for many different configurations of the two-particles system. In Subsection 4.1, we show how the CGPTs of the unknown particle $\tilde{D}_1$ can be reconstructed from the measurements of $\lambda_j$. In Subsection 4.2, we explain the optimal control algorithm to recover the shape of $\tilde{D}_1$ from the CGPTs. In this way, we reconstruct the transformed shape $\tilde{D}_1$ first. Once we find $\tilde{D}_1$, the original shape of $D_1$ can be easily recovered by using the mapping $\Phi$. In Subsection 4.3, we provide several numerical examples.

### 4.1 Reconstruction of CGPTs

In this subsection, we propose an algorithm to reconstruct the CGPTs from measurements of the eigenvalues $\lambda_j$. For ease of presentation, we only consider the first two largest eigenvalues $\lambda_1$ and $\lambda_2$. We denote their measurements by $\mathcal{P}_1$ and $\mathcal{P}_2$, respectively. Note that a single measurement of $(\mathcal{P}_1, \mathcal{P}_2)$ typically yields very poor reconstruction of the CGPTs due to the lack of information. To overcome this issue, we need to measure the eigenvalues for different configurations of the two particles. Recall the target particle contains the origin. We can rotate it around the origin multiple times and measure $(\mathcal{P}_1, \mathcal{P}_2)$ for each configuration. The CGPTs for the target particle after each rotation are related in the following way.
Define
\begin{align*}
N_{m,n}^{(1)}(\lambda, D) &= (M_{cc}^{m,n} - M_{ss}^{m,n}) + i(M_{cs}^{m,n} + M_{sc}^{m,n}), \\
N_{m,n}^{(2)}(\lambda, D) &= (M_{cc}^{m,n} + M_{ss}^{m,n}) + i(M_{cs}^{m,n} - M_{sc}^{m,n})
\end{align*}
and let \( R_\theta D = \{ e^{i\theta} x : x \in D \}, \theta \in [0, 2\pi) \). Then for all integers \( m, n \) and all angle parameters \( \theta \), we have \( N_{m,n}^{(1)}(R_\theta D) = e^{i(n+m)\theta} N_{m,n}^{(1)}(D) \), \( N_{m,n}^{(2)}(R_\theta D) = e^{i(n-m)\theta} N_{m,n}^{(2)}(D) \).

Let us write \( d = c\delta \) for some \( c > 0 \). As discussed in subsection 3.2, if \( c \) is of order one, then the deformation of the shape \( \tilde{D}_1 \) from \( D_1 \) is not so strong. So, if the domain \( D_1 \) is rotated by an angle \( \theta \), then the transformed domain will also be rotated by the same amount of angle. So we may (approximately) identify \( \tilde{R}_\theta \tilde{D}_1 \) with \( R_\theta \tilde{D}_1 \).

Measuring \( P_j \) for multiple rotation angles \( \theta_i \) for \( R_\theta \tilde{D}_1 \) will yield a non-linear system of equations that will allow the recovery of the CGPTs associated with \( \tilde{D}_1 \). From the recovered CGPTs, we will reconstruct the shape of \( \tilde{D}_1 \). Here, we only consider the shape reconstruction problem. Nevertheless, by using the CGPTs associated with \( \tilde{D}_1 \), it is possible to reconstruct the permittivity \( \varepsilon_1 \) of \( \tilde{D}_1 \) in the case it is not a priori given \[2\].

In view of (3.21) and (3.22), using a standard perturbation method, the asymptotic expansion of the eigenvalue \( \lambda_j, j = 1, 2, \) is given by
\[
\lambda_j = \lambda_j^0 + \lambda_j^1 + \lambda_j^2 + \cdots, \quad \text{where} \quad \lambda_j^k = O\left( \frac{\hat{r}_1}{\hat{r}_2} \right)^{k+2}.
\] (4.1)
Each term in the RHS of the above expansion can be computed explicitly. Although we omit the explicit expressions, we mention that they are nonlinear and depend on CGPTs in the following way:
\[
\begin{align*}
\lambda_j^0 &= \lambda_j^0(M_{11}), \\
\lambda_j^1 &= \lambda_j^1(M_{11}, M_{12}), \\
\lambda_j^2 &= \lambda_j^2(M_{11}, M_{12}, M_{22}, M_{13}), \\
&\vdots \\
\lambda_j^k &= \lambda_j^k(\cup_{m+n \leq k+2} \{ M_{mn} \}).
\end{align*}
\]
Suppose we have measurements \( P_1(\theta) \) and \( P_2(\theta) \) for 11 different rotation angles \( \theta_1, \theta_2, \ldots, \theta_{11} \) of the unknown particle \( \tilde{D}_1 \). We can reconstruct \( M_{mn} \) approximately for \( m + n \leq 5 \). Recall that \( M_{mn} = M_{nm}^T \) where subscript \( T \) stands for the transpose. We look for a set of matrices
\{M_{nm}\}_{m+n\leq 5} \text{ satisfying } [M_{nm}^{(1)}]^T = M_{mn}^{(1)} \text{ and the following nonlinear system: for } j = 1, 2,

\begin{align*}
P_j(\theta_1) &= \sum_{l=0}^{3} \lambda^j_l \left( \cup_{m+n \leq l+2} \{M_{nm}^{(1)}(R_{\theta_1 \bar{D}_1})\} \right), \\
P_j(\theta_2) &= \sum_{l=0}^{3} \lambda^j_l \left( \cup_{m+n \leq l+2} \{M_{nm}^{(1)}(R_{\theta_2 \bar{D}_1})\} \right), \\
\vdots
\end{align*}

Let

\begin{align*}
P_j(\theta_{11}) &= \sum_{l=0}^{3} \lambda^j_l \left( \cup_{m+n \leq l+2} \{M_{nm}^{(1)}(R_{\theta_{11} \bar{D}_1})\} \right).
\end{align*}

We note that the above equations have 22 independent parameters. They can be solved by using standard optimization methods. We expect that

\begin{align*}
M_{nm} = M_{nm}^{(1)} + O\left( (\bar{r}_1/\bar{r}_2)^6 \right) \quad \text{for } m + n \leq 5.
\end{align*}

The above scheme can be easily generalized to reconstruct the higher order CGPTs $M_{nm}$. This requires more measurement data ($P_1, P_2$) from more rotations. Let $k \geq 2$. One can see that (using the symmetry $[M_{nm}^{(k)}]^T = M_{nm}^{(k)}$) the set of GPTs $M_{nm}^{(k)}$ satisfying $m + n \leq 4k + 1$ contains $e_k$ independent parameters, where $e_k$ is given by

\begin{align*}
e_k = 16k^2 + 6k.
\end{align*}

Therefore, we need $e_k/2$ pairs of ($P_1, P_2$) to reconstruct these GPTs. Let $\{M_{nm}^{(k)}\}_{m+n\leq 4k+1}$ be the set of matrices satisfying $[M_{nm}^{(k)}]^T = M_{nm}^{(k)}$ and the following system of equations:

\begin{align*}
P_j(\theta_i) &= \sum_{l=0}^{k-1} \lambda^j_l \left( \cup_{m+n \leq l+2} \{M_{nm}^{(k)}(R_{\theta_1 \bar{D}_1})\} \right), \quad i = 1, ..., e_k, \quad j = 1, 2.
\end{align*}

Then we have

\begin{align*}
M_{nm} = M_{nm}^{(k)} + O\left( (\bar{r}_1/\bar{r}_2)^{4k+2} \right) \quad \text{for } m + n \leq 4k + 1.
\end{align*}

### 4.2 Optimal control approach

Now, in order to recover the shape of $\bar{D}_1$ from the CGPTs $M_{nm}$, we can minimize the following energy functional

\begin{align*}
\mathcal{J}_c^{(l)}[B] := \frac{1}{2} \sum_{H,F\in\{c,s\}} \sum_{n+m \leq k} \left| M_{mn}^{HF}(\lambda_{D_1}, B) - M_{mn}^{HF}(\lambda_{D_1}, \bar{D}_1) \right|^2, \quad (4.2)
\end{align*}

We apply the gradient descent method for the minimization. We need the shape derivative of the functional $\mathcal{J}_c^{(l)}[B]$. For $\epsilon$ small, let $B_\epsilon$ be an $\epsilon$-deformation of $B$, i.e., there is a scalar function $h \in C^1(\partial B)$, such that

\begin{align*}
\partial B_\epsilon := \{x + \epsilon h(x)\nu(x) : x \in \partial B\}.
\end{align*}
According to [2, 3, 6], the perturbation of the CGPTs due to the shape deformation is given by

\[
M_{nm}^{HF}(\lambda D_1, B) - M_{nm}'(\lambda D_1, B) = \epsilon(k\lambda D_1 - 1) \int_{\partial B} h(x) \left[ \frac{\partial u}{\partial \nu} \bigg|_+ - \frac{\partial v}{\partial \nu} \bigg|_- + \frac{1}{k\lambda D_1} \frac{\partial u}{\partial T} \bigg|_+ - \frac{\partial v}{\partial T} \bigg|_- \right] (x) \, d\sigma(x) + O(\epsilon^2),
\]

(4.3)

where

\[
k\lambda D_1 = \frac{(2\lambda D_1 + 1)}{(2\lambda D_1 - 1)},
\]

(4.4)

and \(u\) and \(v\) are respectively the solutions to the following transmission problems:

\[
\begin{align*}
\Delta u &= 0 \quad \text{in } B \cup (\mathbb{R}^2 \setminus B), \\
|u|_+ - |u|_- &= 0 \quad \text{on } \partial B, \\
\frac{\partial u}{\partial \nu} |_+ - k\lambda D_1 \frac{\partial u}{\partial \nu} |_- &= 0 \quad \text{on } \partial B, \\
(u - H)(x) &= O(|x|^{-1}) \quad \text{as } |x| \to \infty,
\end{align*}
\]

(4.5)

and

\[
\begin{align*}
\Delta v &= 0 \quad \text{in } B \cup (\mathbb{R}^2 \setminus B), \\
k\lambda D_1 v|_+ - v|_- &= 0 \quad \text{on } \partial B, \\
\frac{\partial v}{\partial \nu} |_+ - \frac{\partial v}{\partial \nu} |_- &= 0 \quad \text{on } \partial B, \\
(v - F)(x) &= O(|x|^{-1}) \quad \text{as } |x| \to \infty.
\end{align*}
\]

(4.6)

Here, \(\partial/\partial T\) is the tangential derivative. In the case of \(M_{nm}^{cs}\), for example, we put \(H = \text{Re}\{P_n\} = r^n \cos n\theta\) and \(F = \text{Im}\{P_m\} = r^n \sin n\theta\). The other cases can be handled similarly.

Let

\[
w_{m,n}^{HF}(x) = (k\lambda D_1 - 1) \left[ \frac{\partial u}{\partial \nu} \bigg|_+ - \frac{\partial v}{\partial \nu} \bigg|_- + \frac{1}{k\lambda D_1} \frac{\partial u}{\partial T} \bigg|_+ - \frac{\partial v}{\partial T} \bigg|_- \right] (x), \quad x \in \partial B.
\]

The shape derivative of \(J_c^{(l)}\) at \(B\) in the direction of \(h\) is given by

\[
\langle dS J_c^{(l)}[B], h \rangle = \sum_{H,F \in \{c,s\}} \sum_{m+n \leq k} \delta_N^{HF}(w_{m,n}^{HF}, h)_{L^2(\partial B)},
\]

where

\[
\delta_N^{HF} = M_{nm}^{HF}(\lambda D_1, B) - M_{nm}'(\lambda D_1, B).
\]

By using the shape derivatives of the CGPTs, we can get an approximation for the matrix \((\tilde{M}_{nm}(\lambda D_1, B))_{n,m=1}^N\) for the slightly deformed shape. Next, the shape derivative of \(\lambda_c^N(B)\) can be computed by using the standard eigenvalue perturbation theory. Finally, by applying a gradient descent algorithm, we can minimize, at least locally, the energy functional \(J_c^{(l)}\). Then we get the shape of the original particle \(D_1\) using \(D_1 = \Phi^{-1}(\tilde{D}_1)\).
4.3 Numerical examples

In this subsection, we support our theoretical results by numerical examples. In the sequel, we set \( \delta = 0.001 \). We also assume that \( B_1 \) and \( B_2 \) are disks of radii \( r_1 = \delta \) and \( r_2 = 1 \), respectively and they are separated by a distance \( d = 5\delta \). Then the ratio \( \tilde{r}_1/\tilde{r}_2 \) between the transformed radii is approximately 0.127. Note that the ratio is rather small but much larger than the small parameter \( \delta \). We suppose that the material parameter \( \varepsilon_1 \) of \( D_1 \) is known and to be given by \( \varepsilon_1 = 3 \) and so, it holds that \( \lambda_{D_1} = 1 \).

We rotate the unknown particle \( D_1 \) by the angle \( \theta_i, i = 1, 2, \ldots, 11 \) and get the measurement pair \( (\mathcal{P}_1(\theta_i), \mathcal{P}_2(\theta_i)) \) for each rotation \( \theta_i \), where \( \theta_i \) is given by

\[
\theta_i = \frac{2\pi}{11}(i - 1), \quad i = 1, 2, \ldots, 11.
\]

We mention that, as discussed in [11], we can measure \( (\mathcal{P}_1, \mathcal{P}_2) \) from the local peaks of the plasmonic resonant far-field.

Figure 3 shows the shift in the plasmonic resonance. In the absence of the dielectric particle \( D_1 \), the local peak occurs only at \( \lambda_{D_2} = 0 \). If the particle \( D_1 \) is presented in a strong regime, then many local peaks appear. By measuring the first two largest values of \( \lambda_{D_2} \) at which a local peak appear, we get \( (\mathcal{P}_1, \mathcal{P}_2) \) approximately.

From measurements of \( (\mathcal{P}_1, \mathcal{P}_2) \), we recover the contracted GPTs using the algorithm described in subsection 4.1. We then minimize functional (4.2) to reconstruct an approximation of \( \tilde{D}_1 \). Finally, we use \( D_1 = \Phi^{-1}(\tilde{D}_1) \) to get the shape of \( D_1 \). We consider the case of \( D_1 \) being a flower-shaped particle and show comparison between the target shapes and the reconstructed ones, as shown in Figure 4. We recover the first contracted GPTs up to order 5, i.e., \( M_{mn} \) for \( m + n \leq 5 \). We take as an initial guess the equivalent ellipse to \( \tilde{D}_1 \), determined from the recovered first order polarization tensor. The required number of iterations is 30. It is clear that they are in good agreement.

5 Conclusion

In this paper, we have made the mathematical foundation of near field sensing complete. We have considered the sensing of a small target particle using a plasmonic particle in the strong interaction regime, where the distance between the two particles is comparable to the small size of the target particle. We have introduced a conformal mapping which transforms the two-particle system into a shell-core structure, in which the inner dielectric core corresponds to the target object. Then we have analyzed the shift in the resonance frequencies due to the presence of the inner dielectric core. We have shown that this shift encodes information on the contracted polarization tensors of the core, from which one can reconstruct its shape, and hence the target object. It is worth to mention that although we considered the two dimensional case only in this paper, our conformal mapping approach can be extended to the three dimensional case. Although the Laplacian is not preserved in 3D, there is a nice way to overcome this difficulty [39]. The extension to the 3D case will be the subject of a forthcoming paper.
Figure 3: The magnitude of the polarization tensor. The dotted line (or solid line) represents the case when the dielectric particle $D_1$ is absent (or presented), respectively. We set $\text{Im}\{\lambda_2\} = 0.003$.

Figure 4: Comparison between the original shape (gray) of the particle $D_1$ and the reconstructed one (black). The iteration number is 30.
