WELL-POSEDNESS AND EXPOENTIAL DECAY FOR THE
EULER-BERNOULLI BEAM CONVEYING FLUID WITH
NON-CONSTANT VELOCITY AND DYNAMICAL BOUNDARY
CONDITIONS

AKRAM BEN AISSA, MAMA ABDELLI, AND ALESSANDRO DUCA

Abstract. In this paper, we consider an Euler-Bernoulli beam equation with time-varying internal fluid. We assume that the fluid is moving non-constant velocity and dynamical boundary conditions are satisfied. By using a semigroup approach, we prove the existence and uniqueness of global solution under suitable assumptions on the tension of beam and on the parameters of the problem. Afterwards, we establish the exponential stability of the solution by introducing a suitable Lyapunov functional.

1. Introduction

In this paper, we study the dynamics of a tubular structure, a flexible pipe, which conveys a moving fluid. We assume that the pipe diameter is negligible compared to its length and we model the system by a one dimensional problem. In this context, the motion of the structure is driven by the following Euler-Bernoulli beam conveying fluid equation

\[
\begin{align*}
(m_p + 2m_f)w_{tt}(t) + EIw_{xxxx}(t) - (T - 2m_fV(t)^2)w_{xx}(t) \\
+ cw_t(t) + 2m_fV(t)w_x(t) + 4m_fV(t)w_{xt}(t) = 0,
\end{align*}
\]

endowed with the boundary conditions

\[
\begin{align*}
w_{xx}(0,t) = w_{xx}(L,t) = w(0,t) = 0, & \quad t > 0, \\
EIw_{xxxx}(L,t) - (T - 2m_fV(t)^2)w_x(L,t) + 2m_fV(t)w_t(L,t) = 0, & \quad t > 0.
\end{align*}
\]

The parameters \(L\) and \(m_p\) are the length and the mass per unit length of the flexible pipe, while \(EI\) and \(T\) are its bending stiffness and its tension. The terms \(m_f\) and \(V(t)\) are the mass per unit length and the velocity of the internal fluid. We assume that the velocity \(V(t)\) is strictly positive or strictly negative (we refer to Section 4 for further details on the general case). The solution of the system (1.1) with boundary conditions (1.2) represents the displacement of the flexible pipe at the position \(x\) and time \(t\) (see Figure 1). We study the well-posedness of (1.1)-(1.2) and the exponential stability of its solutions.

The equation (1.1)-(1.2) has been deduced when the velocity \(V(t)\) is constant by Liu et al in [13] in presence of the environmental disturbances and a boundary control. The
The authors consider the problem of a flexible marine riser and they compute the equation via a suitable energy functional. Finally, they prove the exponential decay of the solutions by Lyapunov method in presence of an additional boundary condition \( w_x(0,t) = 0 \).

In our work, we assume that the tension \( T \) is larger than a specific value \( T^* \) depending on the parameters of the problems. By exploiting such hypotheses, we firstly ensure the well-posedness of the (1.1)-(1.2) and we prove the existence of a strongly continuous semigroup associated to the dynamics. Secondly, we show the exponential stability of the energy of the solutions of (1.1)-(1.2) without considering the additional boundary condition.

Our stability result is obtained by exploiting a different energy functional from the one considered in [13] which validity is due to the assumption imposed on \( T \). Such condition is not surprising from a practical point of view. It is reasonable to assume that the tension of the pipe has to be sufficiently strong, compared to the density and the velocity of the conveyed fluid, in order to have the stability. Otherwise, the fluid inside the pipe may dynamically interacts with its motion, possibly causing the flexible pipe to vibrate.

Euler-Bernoulli beam conveying fluid equations are found in many practical applications. They are used to model for instance risers of offshore platforms, pipes carrying chemical fluids, exhaust pipes in the engines, flue-gases stacks, air-conditioning ducts, tubes in heat exchangers and power plants, etc. A similar dynamics to (1.1) is studied in [8] by Khemmoudj where the internal damping \( c w_t(t,x) \) is replaced by a viscoelastic term. There, the author considers suitable boundary conditions and he proves the exponential stability.
by Lyapunov method. In [4], Conrad et al. consider the equation \( w_{tt} + w_{xxxx} = 0 \) and they prove exponential stability in presence of specific dynamical boundary conditions. For other similar results, we refer to [2,15].

The paper is organized as follows. In Section 2, we present the well-posedness of the equation (1.1)-(1.2) in Theorem 2.1 by virtue of the semigroup methods. In Section 3, we ensure our stability result in Theorem 3.1 by introducing a suitable Lyapunov functional.

2. WELL-POSEDNESS OF THE PROBLEM

The aim of this section is to prove the existence and uniqueness of solutions for (1.1)-(1.2). To this purpose, we define the space
\[ V = \{ w \in H^2((0,L),\mathbb{R}) \mid w(0) = 0 \} \]
and the Hilbert space
\[ H = \{ (w,v) \mid w \in V, v \in L^2((0,L),\mathbb{R}) \} \]
equipped with the norm \( \| \cdot \|_H \) induced by the scalar product
\[ \langle f_1, f_2 \rangle_H = \int_0^L \left( \partial_x^2 w_1 \partial_x^2 w_2 + \partial_x w_1 \partial_x w_2 + v_1 v_2 \right) dx, \quad f_1 = (w_1, v_1), \quad f_2 = (w_2, v_2) \in H. \]
We define the family \( \{ A_0(t) \}_{t \in [0,T]} \) of operators in \( H \) such that
\[ A_0(t) f = A_0(t) \begin{pmatrix} w \\ v \end{pmatrix} = \begin{pmatrix} -\frac{EI}{m_p + 2m_f} w_{xxxx} + \frac{T - 2m_f V^2(t)}{m_p + 2m_f} w_{xx} - \frac{4m_f V(t)}{m_p + 2m_f} v_x \\ 0 \end{pmatrix}, \]
for every \( f \) in the domain \( D(A_0(t)) \) defined by
\[ D(A_0(t)) = \{ (w,v) \in H \mid w \in V \cap H^4, v \in V, w_{xx}(0) = w_{xx}(L) = 0, \]
\[ 2m_f V(t) v(L) = -EIw_{xxx}(L) + (T - 2m_f V^2(t))w_x(L) \}. \]
Let \( \{ B(t) \}_{t \in [0,T]} \) be the family of bounded operators in \( H \) such that
\[ B(t) f = \begin{pmatrix} 0 \\ -\frac{c}{m_p + 2m_f} v + \frac{2m_f V(t)}{m_p + 2m_f} w_x \end{pmatrix}, \quad \forall f \in H, \]
By imposing \( v = w_t \), the Cauchy problem (1.1)-(1.2) becomes the following one in \( H \)
\[ (2.1) \quad \begin{pmatrix} w_t \\ v_t \end{pmatrix} = A(t) \begin{pmatrix} w \\ v \end{pmatrix}, \quad A(t) := (A_0(t) + B(t)), \]
endowed with the boundary conditions (1.2). The main result of this section is the well-posedness of the dynamics of (2.1)-(1.2) in $\mathcal{H}$ which is presented by the following theorem.

**Theorem 2.1.** Let $V \in C^1([0, \tau], \mathbb{R})$ be a strictly positive or strictly negative function for $\tau > 0$. Let $T > 0$ be such that $T > 2m_f \sup_{t \in [0, \tau]} V^2(t)$ for $\tau > 0$. The family of operators $(\mathcal{A}(t), D(\mathcal{A}_0(t)))$ with $t \in [0, \tau]$ generates a strongly continuous $C_0$-semigroup on $\mathcal{H}$.

Theorem 2.1 ensures the well-posedness of (2.1) endowed with the boundary conditions (1.2), and then of (1.1)-(1.2). The result is guaranteed when the tension $T$ is sufficiently large with respect to the velocity $V(t)$ and to the mass $m_f$.

The following proposition is the core of the proof of Theorem 2.1. It ensures the existence of a strongly continuous $C_0$-semigroup on $\mathcal{H}$ generated by the family of operators $(\mathcal{A}_0(t), D(\mathcal{A}_0(t)))$. Such result and classical arguments of semigroup theory lead to Theorem 2.1 thanks to the properties of the family of operators $B(t)$.

**Proposition 2.2.** Let $V \in C^1([0, \tau], \mathbb{R})$ be a strictly positive or strictly negative function for $\tau > 0$. Let $T > 0$ be such that $T > 2m_f \sup_{t \in [0, \tau]} V^2(t)$. The family of operators $(\mathcal{A}_0(t), D(\mathcal{A}_0(t)))$ with $t \in [0, \tau]$ generates a strongly continuous $C_0$-semigroup on $\mathcal{H}$.

**Proof.** Thanks to the assumptions on the velocity $V(t)$, we can define the norm $\| \cdot \|_t$ for every $t \in [0, \tau]$ of $\mathcal{H}$ induced by the scalar product

$$\langle f_1, f_2 \rangle_t = \int_0^L \left( \alpha(t) \partial_x^2 w_1 \partial_x^2 w_2 + \beta(t) \partial_x w_1 \partial_x w_2 + \gamma(t)v_1 v_2 \right) dx,$$

for every $f_1 = (w_1, v_1)$ and $f_2 = (w_2, v_2) \in \mathcal{H}$ with

$$\alpha := \frac{EI}{2m_f}, \quad \beta(t) = \frac{T - 2m_f V^2(t)}{2m_f}, \quad \gamma = \frac{m_p + 2m_f}{2m_f}.$$

Now, the choice of the potential $V$ yields that there exists $C > 1$ such that

$$C^{-1} \| \cdot \|_H \leq \| \cdot \|_t \leq C \| \cdot \|_H, \quad \forall t \in [0, \tau].$$

The domain of $\mathcal{A}_0(t)$ can be rewritten in terms of the parameters $\alpha$ and $\beta(t)$ as follows

$$D(\mathcal{A}_0(t)) = \left\{ (w, v) \in \mathcal{H} \mid w \in \mathcal{V} \cap H^4, \ v \in \mathcal{V}, \ w_{xx}(0) = w_{xx}(L) = 0, \ V(t)v(L) = -\alpha w_{xxx}(L) + \beta(t)w_x(L) \right\}.$$

1) **Dissipative property.** First, we prove that $\mathcal{A}_0(t)$ is dissipative for every $t \in [0, \tau]$ in $\mathcal{H}$ with respect to the scalar product $\langle \cdot, \cdot \rangle_t$. Let us denote

$$a_1 := -\frac{EI}{m_p + 2m_f}, \quad a_2(t) := \frac{T - 2m_f V^2(t)}{m_p + 2m_f}, \quad a_3(t) := -\frac{4m_f V(t)}{m_p + 2m_f},$$

For every $f \in D(\mathcal{A}_0(t))$, thanks to the relations

$$\gamma a_1 = -\alpha, \quad \gamma a_2(t) = \beta(t), \quad \gamma(t)a_3(t) = -2V(t),$$

...
there holds
\[ \langle f, \mathcal{A}_0(t) f \rangle_t = \int_0^L \left( \alpha w_{xx} v_{xx} + \beta(t) w_x v_x + \gamma (a_1 w_{xxxx} + a_2(t) w_{xx} + a_3(t) v_x) v \right) dx \]
\[ = -\alpha w_{xxx}(L) v(L) + \beta(t) w_x(L) v(L) \]
\[ + \int_0^L \left( (\alpha + \gamma a_1) w_{xxxx} + (\beta(t) - \gamma a_2(t)) w_{xx} + \gamma a_3(t) v_x \right) dx \]
\[ = (-\alpha w_{xxx}(L) + \beta(t) w_x(L)) v(L) - \int_0^L 2V(t) v_x v dx \]
\[ = V(t) v(L)^2 - V(t) v(L)^2 = 0. \]

2) Surjectivity conditions. Second, fixed \( t \in [0, \tau] \), we ensure the surjectivity of the map
\[ (\lambda I - \mathcal{A}_0(t)) : D(\mathcal{A}_0(t)) \subset \mathcal{H} \rightarrow \mathcal{H} \]
for every \( \lambda > 0 \). The property is equivalent to prove that, for every \( f^* = (w^*, v^*) \in \mathcal{H} \), there exists a unique solution \( f = (w, v) \in D(\mathcal{A}_0(t)) \) of the equation \((\lambda I - \mathcal{A}_0(t)) f = f^*\).
In other words, we need to study the existence of a unique solution of the following system of equations
\[
\begin{align*}
\lambda w(x) - v(x) &= w^*(x), \\
\lambda v(x) - a_1 w_{xxxx}(x) - a_2(t) w_{xx}(x) - a_3(t) v_x(x) &= v^*(x), \\
V(t) v(L) &= -\alpha w_{xxx}(L) + \beta(t) w_x(L), \\
w_{xx}(0) &= w_{xx}(L) = w(0) = 0.
\end{align*}
\]
Solving the previous system is equivalent to study
\[
\begin{align*}
\lambda^2 w - a_1 w_{xxxx} - a_2(t) w_{xx} - a_3(t) \lambda w_x &= v^* - a_3(t) w_x^* + \lambda w^*, \\
\lambda V(t) w(L) - V(t) w^*(L) &= -\alpha w_{xxx}(L) + \beta(t) w_x(L), \\
w_{xx}(0) &= w_{xx}(L) = w(0) = 0.
\end{align*}
\]
Let \( g^* = v^* - a_3(t) w_x^* + \lambda w^* \). The weak formulation of the previous system is given by
\[
\int_0^L \left( \lambda^2 w \phi - a_1 w_{xx} \phi_{xx} + a_2(t) w_x \phi_x - a_3(t) \lambda w_x(x) \phi \right) dx
\]
\[ - a_1 w_{xxx}(L) \phi(L) - a_2(t) w_x(L) \phi(L) = \int_0^L g^* \phi dx \]
with \( \phi \in \mathcal{V} \). The identity (2.4) can be rewritten as
\[
\int_0^L \left( \lambda^2 w \phi - a_1 w_{xx} \phi_{xx} + a_2(t) w_x \phi_x - a_3(t) \lambda w_x(x) \phi \right) dx
\]
\[ + \gamma^{-1} (\alpha w_{xxx}(L) - \beta(t) w_x(L)) \phi(L) = \int_0^L g^* \phi dx, \]
Thanks to the validity of the boundary conditions in $L$, we have

$$\int_0^L \left( \lambda^2 w \phi - a_1 w_{xx} \phi_{xx} + a_2(t) w_x \phi_x - a_3(t) \lambda w_x \phi \right) dx - \gamma^{-1} \lambda V(t) w(L) \phi(L)$$

$$= -\gamma^{-1} V(t) w^*(L) \phi(L) + \int_0^L g^* \phi dx.$$ 

We consider the bilinear form $\langle \cdot, \cdot \rangle_{A_0(t)}$ in $V$ such that, for every $w, \phi \in V$,

$$\langle w, \phi \rangle_{A_0(t)} = \int_0^L \left( \lambda^2 w \phi - a_1 w_{xx} \phi_{xx} + a_2(t) w_x \phi_x - a_3(t) \lambda w_x \phi \right) dx - \gamma^{-1} \lambda V(t) w(L) \phi(L).$$

We notice that, for every $w \in V$,

$$\langle w, w \rangle_{A_0(t)} = \int_0^L \left( \lambda^2 w^2 - a_1 w_{xx}^2 + a_2(t) w_x^2 \right) dx - \left( \frac{a_3(t)}{2} + \gamma^{-1} V(t) \right) \lambda w(L)^2.$$ 

Thanks to the identity

$$\frac{a_3(t)}{2} + \gamma^{-1} V(t) = 0,$$

$\langle \cdot, \cdot \rangle_{A_0(t)}$ is a coercive bilinear form as $-a_1 > 0$ and $a_2(t) > 0$. From the Lax-Milgram theorem, the weak formulation admits an unique solution. Thanks to the regularity of $w \in H^4((0, L), \mathbb{R})$ and by using particular $\phi$, it is possible to recover the boundary conditions in $w$ and $v$ is defined by (2.3) which is unique. Now, $f = (w, v) \in D(A_0(t))$. This shows the surjectivity, for every $\lambda > 0$, of the map $(\lambda I - A_0(t)) : D(A_0(t)) \subset \mathcal{H} \rightarrow \mathcal{H}$.

3) Conclusion. Thanks to the point 1), the operator $A(t)$ is dissipative for $t \in [0, \tau]$ and then, for every $\lambda > 0$,

$$\|(\lambda I - A_0(t)) \psi\|_t \geq \lambda \|\psi\|_t, \quad \psi \in D(A_0(t)).$$

Now, we define a new norm of $\mathcal{H}$

$$\| \cdot \|'_t := m(t) \| \cdot \|_t, \quad \forall t \in [0, \tau]$$

by choosing a suitable strictly positive function $m : [0, T] \rightarrow \mathbb{R}^+$ such that there exists $C > 1$ such that

$$C^{-1} \| \cdot \|_t \leq \| \cdot \|'_s \leq \| \cdot \|'_t \leq C \| \cdot \|'_s, \quad \forall 0 \leq s \leq t \leq \tau$$

(by keeping in mind the validity of the inequality (2.2)). Thus, we have

$$\|(\lambda I - A_0(t)) \psi\|'_t \geq \lambda \|\psi\|'_t, \quad \forall \lambda > 0, \ \psi \in D(A_0(t)).$$

Let us denote, for every $t \in [0, \tau]$ and $x \in [0, L]$,

$$f(t, x) = \left( 1 + \frac{x}{L} \left( \frac{|V(t)|}{\alpha} - 1 \right) \right).$$
\[
g(t, x) = \text{sign}(V(t)) \frac{\beta(t) x}{\alpha L}.
\]

We introduce the family of operators \( \Gamma_t \) with \( t \in [0, \tau] \) such that
\[
\Gamma_t: (w, v) \mapsto (w, f(t, \cdot)v - g(t, \cdot)w).
\]
We notice that
\[
\Gamma_t(D(A_0(t))) = \{(w, v) \in \mathcal{H} \mid w \in \mathcal{V} \cap H^4, v \in \mathcal{V}, w_{xx}(0) = w_{xx}(L) = 0, v(L) = -\text{sign}(V(t))w_{xxx}(L)\}
\]
which does not depend on time since \( V(t) \) has constant sign. Each \( \Gamma_t: \mathcal{H} \to \mathcal{H} \) is invertible and \( \Gamma_t^{-1} \) is a family of linear bounded and invertible operators satisfying [10] hypotheses (4.3) and (4.4); p. 309. In conclusion, the validity of [10] Theorem 4.2 yields that \((A_0(t), D(A_0(t)))\) with \( t \in [0, \tau] \) generates a strongly continuous \( C_0 \)-semigroup. \( \square \)

**Proof of Theorem 2.1** The statement follows from Proposition 2.2 and [10] Theorem 5.1 thanks to the smoothness of the bounded operator \( B(t) \) which is due to hypotheses imposed on the velocity \( V(t) \). \( \square \)

3. **Exponential stability of the problem**

**Main result**

In this section, we ensure the stability result for the solution of the problem (1.1)-(1.2). To the purpose, we introduce the following assumptions in a time interval \([0, \tau]\).

**Assumptions I.** Let \( V \in C^1([0, \tau], \mathbb{R}) \) be a strictly positive or strictly negative function. Let \( T > 0 \) be such that
\[
T > 2m_f \sup_{t \in [0, \tau]} V(t)^2 + \max\{T_1, T_2\},
\]
where we denote
\[
T_1 = \frac{L^2}{4}(m_p + 2m_f) + 2\sqrt{2}Lm_f \sup_{t \in [0, \tau]} |V(t)|
\]
and
\[
T_2 = \frac{c^2L^2}{8(c - m_p - 2m_f)} + 2m_f \sup_{t \in [0, \tau]} |V(t)V(t)|.
\]

Assumptions I ensure that the tension \( T \) of the beam is sufficiently strong with respect to the velocity \( V \) and to the parameters of the problem. In this framework, the quantity \( \frac{T}{2} - m_f V^2(t) > 0 \) for every \( t \in [0, \tau] \) and it is valid the well-posedness result provided in the
previous section by Theorem 2.1. In addition, the assumption on $T$ allows us to consider the following energy functional associated to the solutions of (1.1)-(1.2)

$$E(t) = \frac{1}{2} (m_p + 2m_f) \int_0^L w_t^2(t) dx + \frac{EI}{2} \int_0^L w_{xx}^2(t) dx$$

$$+ \left( \frac{T}{2} - m_f V^2(t) \right) \int_0^L w_x^2(t) dx.$$ \hspace{1cm} (3.1)

We are finally ready to state the stability result of the problem (1.1)-(1.2).

**Theorem 3.1.** Let the problem (1.1)-(1.2) satisfy Assumptions I in the time interval $[0, \tau]$. There exists two positive constants $k_0$ and $k_1$, such that for any solution $w$ of (1.1)-(1.2), the energy functional (3.1) decays as follows

$$E(t) \leq k_0 e^{-k_1 t} \quad \forall t \in [0, \tau].$$ \hspace{1cm} (3.2)

The proof of Theorem 3.1 is established in the final part of the section by gathering different results. We firstly compute the time derivative of the energy functional $\frac{d}{dt} E(t)$. After, we introduce a suitable Lyapunov functional $L(t)$ for which there exist $C_1, C_2 > 0$ so that $C_1 E(t) \leq L(t) \leq C_2 E(t)$. Finally, we show the existence of $C_3 > 0$ such that $\frac{d}{dt} L(t) \leq -C_3 L(t)$. This identity implies $L(t) \leq L(0) e^{-C_3 t}$ and Theorem 3.1 is proved by gathering the previous results.

**Some preliminaries**

We start by recalling the following Sobolev-Poincaré inequality (see [1] for further details).

**Lemma 3.2.** (Sobolev-Poincaré inequality) For every $v \in \{ w \in H^1(0, L) \mid w(0) = 0 \}$, there holds

$$\int_0^L v^2 dx \leq P \int_0^L v_x^2 dx, \quad \text{with} \quad P := \frac{L^2}{2}.$$ \hspace{1cm}

**Lemma 3.3.** Let $w$ be a solution of the problem (1.1)-(1.2). The energy functional defined by (3.1) satisfies

$$\frac{d}{dt} E(t) = c \int_0^L w_t^2(t) dx - 2m_f V(t) \int_0^L w_t(t) w_x(t) dx$$

$$- 2m_f V(t) V(t) \int_0^L w_x^2(t) dx.$$
Proof. By multiplying the first equation in (1.1) with \( w_t \) and by integrating over \((0, L)\), we obtain

\[
\int_0^L w_t(t) \left[(m_p + 2m_f)w_{tt}(t) + EIw_{xxxx}(t)\right] - (T - 2m_fV^2(t))w_{xx}(t) \, dx + 4m_fV(t) \int_0^L w_t(t)w_{xt}(t) \, dx = -c \int_0^L w_t^2(t) \, dx - 2m_fV(t) \int_0^L w(t)w_x(t) \, dx.
\]  

(3.3)

We study each term appearing in first integral of (3.3)

\[
(m_p + 2m_f) \int_0^L w_t(t)w_{tt}(t) \, dx = \frac{1}{2}(m_p + 2m_f) \frac{d}{dt} \int_0^L w_t^2(t) \, dx,
\]

(3.4)

\[
EI \int_0^L w_t(t)w_{xxxx}(t) \, dx = EI w_t(L,t)w_{xxx}(L,t) + \frac{EI}{2} \frac{d}{dt} \int_0^L w_x^2(t) \, dx
\]

and

\[
-(T - 2m_fV^2(t)) \int_0^L w_t(t)w_{xx}(t) \, dx = (2m_fV^2(t) - T) w_t(L,t)w_x(L,t)
\]

\[
+ \frac{T}{2} \frac{d}{dt} \int_0^L w_x^2(t) \, dx - m_fV^2(t) \frac{d}{dt} \int_0^L w_x^2(t) \, dx.
\]

(3.6)

The right-hand side of (3.6) can be rewritten as follows

\[
(2m_fV^2(t) - T) w_t(L,t)w_x(L,t) + \frac{T}{2} \frac{d}{dt} \int_0^L w_x^2(t) \, dx
\]

\[
- m_f \frac{d}{dt} \left(V^2(t) \int_0^L w_x^2 \, dx\right) + 2m_fV(t)V(t) \int_0^L w_x^2 \, dx.
\]

(3.7)

Now, we investigate the remaining term in the left-hand side of (3.3)

\[
4m_fV(t) \int_0^L w_t(t)w_{xt}(t) \, dx = 2m_fV(t)w_t^2(L,t).
\]

(3.8)

By using (3.4)-(3.8) into (3.3) yields the following expression

\[
\frac{d}{dt} E(t) + \left(EI w_{xxx}(L,t) - (T - 2m_fV^2(t))w_x(L,t) + 2m_fV(t)w_t(L,t)\right) w_t(L,t)
\]

\[
= -c \int_0^L w_t^2(t) \, dx - 2m_fV(t) \int_0^L w_t(t)w_x(t) \, dx - 2m_fV(t)V(t) \int_0^L w_x^2(t) \, dx.
\]

The boundary conditions (1.2) complete the proof. \(\square\)
A suitable Lyapunov functional

Let us introduce the functionals

\[
G_1(t) = (m_p + 2m_f) \int_0^L w(t)w_t(t) \, dx,
\]
\[
G_2(t) = 2m_fV(t) \int_0^L w(t)w_x(t) \, dx,
\]
and

\[
G(t) = G_1(t) + G_2(t).
\]

We define the Lyapunov functional \( L \) such that

\[
L(t) = E(t) + G(t).
\]

Lemma 3.4. Let the problem (1.1)-(1.2) satisfy Assumptions I in a time interval \([0, \tau]\). There exist two positive constants \( \xi_1 > 0 \) and \( \xi_2 > 0 \) depending on \( m_p, m_f, T \) and \( V(t) \) such that, for all \( t > 0 \),

\[
\xi_1 E(t) \leq L(t) \leq \xi_2 E(t).
\]

Proof. Let \( P \) be the Poincaré’s constant from Lemma 3.2 and \( \alpha_1 > 0 \). By using the Young’s and the Poincaré inequalities, we obtain

\[
|G_1(t)| \leq \frac{\alpha_1}{2} (m_p + 2m_f) \int_0^L w_t^2(t) \, dx
\]
\[
+ \frac{P}{2\alpha_1} (m_p + 2m_f) \int_0^L w_x^2(t) \, dx.
\]

By setting \( \alpha_2 = \frac{1}{P} \), we have

\[
|G_2(t)| \leq 2m_f|V(t)| \left( \frac{\alpha_2 P}{2} + \frac{1}{2\alpha_2} \right) \int_0^L w_x^2(t) \, dx
\]
\[
= 2m_f|V(t)| \sqrt{P} \int_0^L w_x^2(t) \, dx
\]

In the last relation, we impose \( \alpha_2 = \frac{1}{P} \) in order to minimize the function \( \alpha_2 \mapsto \{ \frac{P}{2} \alpha_2 + \frac{1}{2\alpha_2} \} \) which attains its minimum in \( \sqrt{P} \) exactly when \( \alpha_2 = \frac{1}{P} \). By combining (3.1), (3.12) and (3.13), we have

\[
L(t) \leq \left( \frac{T}{2} - m_fV^2(t) + \frac{P}{2\alpha_1} (m_p + 2m_f) + 2m_f|V(t)|\sqrt{P} \right) \int_0^L w_x^2(t) \, dx
\]
\[
+ (m_p + 2m_f) \left( 1 + \frac{\alpha_1}{2} \right) \int_0^L w_t^2(t) \, dx + EI \int_0^L w_{xx}^2(t) \, dx.
\]
For the lower bound, we can see that
\[
\mathcal{L}(t) \geq \left( \frac{T}{2} - m_f V^2(t) - \frac{P}{2\alpha_1} (m_p + 2m_f) - 2m_f |V(t)|\sqrt{P} \right) \int_0^L w_x^2(t) \, dx \\
+ (m_p + 2m_f) \left( 1 - \frac{\alpha_1}{2} \right) \int_0^L w_t^2(t) \, dx + EI \int_0^L w_{xx}^2(t) \, dx.
\]
(3.15)

We recall that \( P = \frac{L^2}{2} \) and, thanks to Assumptions I,
\[
T > 2m_f \sup_{t \in [0,\tau]} V(t)^2 + \frac{L^2}{4} (m_p + 2m_f) + 2\sqrt{2} L m_f \sup_{t \in [0,\tau]} |V(t)|.
\]
(3.16)

Now, we choose \( \alpha_1 \in [1,2] \) in (3.14) and (3.15) as that number such that
\[
\frac{T}{2} - m_f \sup_{t \in [0,\tau]} V(t)^2 + \frac{P}{2\alpha_1} (m_p + 2m_f) - 2m_f \sup_{t \in [0,\tau]} |V(t)|\sqrt{P} > 0,
\]
which existence is guaranteed by (3.16). In addition, \( (m_p + 2m_f)(1 - \frac{\alpha_1}{2}) > 0 \) and
\[
\frac{T}{2} - m_f \inf_{t \in [0,\tau]} V^2(t) \geq \frac{T}{2} - m_f \sup_{t \in [0,\tau]} V^2(t) > 0
\]
thanks to (3.16). By combining (3.14) and (3.15), we obtain (3.11). The constants \( \xi_1 \) and \( \xi_2 \) are explicitly given by
\[
\xi_1 = \max \left\{ \frac{1}{\frac{T}{2} - m_f \sup_{t \in [0,\tau]} V(t)^2} \left( \frac{T}{2} - m_f V^2(t) + \frac{P}{2\alpha_1} (m_p + 2m_f) \\
+ 2m_f \sup_{t \in [0,\tau]} |V(t)|\sqrt{P}, 2 \left( 1 + \frac{\alpha_1}{2} \right), 2 \right) \right\},
\]
\[
\xi_2 = \min \left\{ \frac{1}{\frac{T}{2} - m_f \inf_{t \in [0,\tau]} V^2(t)} \left( \frac{T}{2} - m_f V^2(t) - \frac{P}{2\alpha_1} (m_p + 2m_f) \\
- 2m_f \sup_{t \in [0,\tau]} |V(t)|\sqrt{P}, 2 \left( 1 - \frac{\alpha_1}{2} \right), 2 \right) \right\}.
\]
\[
\text{Lemma 3.5. Let } w \text{ be the solution of (1.1)-(1.2). The functional } G \text{ defined by (3.9) satisfies}
\]
\[
\frac{d}{dt} G(t) = -EI \int_0^L w_{xx}^2(t) \, dx - (T - 2m_f V^2(t)) \int_0^L w_x^2(t) \, dx \\
- c \int_0^L w(t)w_t(t) \, dx + 2m_f V(t) \int_0^L w_x(t)w_t(t) \, dx + (m_p + 2m_f) \int_0^L w_t^2(t) \, dx.
\]
Proof. We know that \( \frac{d}{dt} G(t) = \frac{d}{dt} G_1(t) + \frac{d}{dt} G_2(t) \). Now,
\[
\frac{d}{dt} G_1(t) = (m_p + 2m_f) \int_0^L w(t)w_t(t) \, dx + (m_p + 2m_f) \int_0^L w_t^2(t) \, dx
\]
We use (1.1) and we obtain
\[
\frac{d}{dt} G_1(t) = -EI \int_0^L w_{xxx}(t)w(t) + (T - 2m_fV^2(t)) \int_0^L w_{xx}(t)w(t) \, dx
\]
\[
- 2m_fV_t(t) \int_0^L w_x(t)w(t) \, dx - 4m_fV(t) \int_0^L w_{xt}(t)w(t) \, dx
\]
\[
- c \int_0^L w(t)w_t(t) \, dx + (m_p + 2m_f) \int_0^L w_t^2(t) \, dx.
\]
We integrate by parts and \( \frac{d}{dt} G_1(t) \) becomes
\[
- \left( EI w_{xxx}(L,t) - (T - 2m_fV^2(t)) w_x(L,t) + 2m_fV(t)w_t(L,t) \right) w(L,t)
\]
\[
- EI \int_0^L w_{xx}^2(t) \, dx - (T - 2m_fV^2(t)) \int_0^L w_{xx}(t) \, dx - 2m_fV_t(t) \int_0^L w_x(t)w(t) \, dx
\]
\[
- 2m_fV(t) \int_0^L w_{xt}(t)w(t) \, dx - c \int_0^L w(t)w_t(t) \, dx + (m_p + 2m_f) \int_0^L w_t^2(t) \, dx.
\]
By using the boundary conditions, we obtain
\[
\frac{d}{dt} G_1(t) = -EI \int_0^L w_{xx}^2(t) \, dx - (T - 2m_fV^2(t)) \int_0^L w_{xx}(t) \, dx
\]
\[
- 2m_fV_t(t) \int_0^L w_x(t)w(t) \, dx - 2m_fV(t) \int_0^L w_{xt}(t)w(t) \, dx
\]
\[
- c \int_0^L w(t)w_t(t) \, dx + (m_p + 2m_f) \int_0^L w_t^2(t) \, dx.
\]
(3.17)
Now, we compute \( \frac{d}{dt} G_2(t) \)
\[
\frac{d}{dt} G_2(t) = 2m_fV(t) \int_0^L w_{xt}(t)w(t) \, dx + 2m_fV(t) \int_0^L w_x(t)w_t(t) \, dx
\]
\[
+ 2m_fV_t \int_0^L w(t)w_x(t) \, dx.
\]
(3.18)
By gathering (3.17) and (3.18), we achieve the claim. \( \square \)

**Proof of Theorem 3.1**

Now, we are ready to prove our main result.
Proof of Theorem 3.1 By the definition (3.10), we have \( \frac{d}{dt} \mathcal{L}(t) = \frac{d}{dt} E(t) + \frac{d}{dt} G(t) \). Thanks to Lemma 3.3 and Lemma 3.5, we obtain

\[
\frac{d}{dt} \mathcal{L}(t) = -c \int_0^L w_l(t)^2 dx - 2m_f V_l(t)V(t) \int_0^L w_x^2(t) dx
\]

\( - EI \int_0^L w_{xx}^2(t) dx - (T - 2m_f V^2(t)) \int_0^L w_x^2(t) dx \)

\( - c \int_0^L w(t)w_l(t) dx + (m_p + 2m_f) \int_0^L w_l^2(t) dx. \)

By using Young’s inequality and Poincaré inequality, for every \( \alpha_1 > 0 \), we have

\[
-c \int_0^L w(t)w_l(t) dx \leq c \frac{\alpha_1}{2} \int_0^L w_l(t)^2 dx + \frac{1}{2\alpha_1} c \int_0^L w(t)^2 dx
\]

\( \leq c \frac{\alpha_1}{2} \int_0^L w_l(t)^2 dx + \frac{P}{2\alpha_1} c \int_0^L w_x(t)^2 dx. \)

Now, thanks to Assumptions I, there exists \( \delta \in (0, c - m_p - 2m_f) \) such that

\[
T > 2m_f \sup_{t \in [0,\tau]} V(t)^2 + \frac{c^2 P}{4(c - m_p - 2m_f - \delta)} + 2m_f \sup_{t \in [0,\tau]} |V_l(t)V(t)|.
\]

We set \( \alpha_1 = \frac{2c - m_p - 2m_f - \delta}{c} \) in (3.20) that we use in (3.19) in order to obtain

\[
\frac{d}{dt} \mathcal{L}(t) \leq -\vartheta E(t)
\]

where

\( \vartheta := \min \left\{ \frac{2\gamma_0}{m_p + 2m_f}, \frac{2\gamma_1}{T - 2m_f \inf_{t \in [0,\tau]} V(t)^2} \right\}. \)

A combination of (3.11) and (3.22) gives

\[
\frac{d}{dt} \mathcal{L}(t) \leq -k_1 \mathcal{L}(t), \quad \forall t \in [0,\tau],
\]
where \( k_1 = \frac{\theta}{\xi_2} \). We integrate (3.23) over \((0, t)\) and
\[
L(t) \leq L(0)e^{-k_1 t}, \quad \forall t \in [0, \tau].
\]
Finally, by combining (3.11) and (3.24), we obtain (3.2) with \( k_0 = \frac{\xi_2 E(0)}{\xi_1} \), which completes the proof. \( \square \)

4. Conclusions

In Section 2 and Section 3, we studied the well-posedness and the stability of the solutions of (1.1)-(1.2). We assumed that the velocity \( V(t) \) is a sufficiently smooth function with constant sign, while the tension \( T \) is larger than a specific value \( T^* \) depending on the parameters of the problems. By exploiting such hypotheses, we proved the well-posedness of (1.1)-(1.2) by showing the existence of a strongly continuous semigroup associated to the dynamics. Secondly, we ensured the exponential stability by introducing a suitable Lyapunov functional.

The choice of considering \( V \) with constant sign is due to the following reason. When \( V \) vanishes for some time, the dynamical boundary condition in (1.2) becomes a statical boundary condition. In this case, the problem lacks of a boundary condition on \( w_t(t, x) \) and it is not clear which “natural” boundary condition appears in such a context. Nevertheless, the stability result from Section 3 could still be valid, at least from a formal point of view.

Finally, the assumption on \( T \) is not so surprising when we think to the nature of the problem modeled by (1.1)-(1.2). It is reasonable to assume that the tension of the pipe has to be sufficiently strong, compared to the density and the velocity of the conveyed internal fluid, in order to have the stability. From this perspective, it could be interesting to explore this phenomenon further, at least from a numerical point of view. One could seek for evidences of instability phenomena when the tension \( T \) is too low.

Acknowledgments. The authors are grateful to Kaïs Ammari for suggesting them the problem. The third author also thanks the colleagues Romain Joly and Nabile Boussaïd for the fruitful discussions on the well-posedness of the problem. The third author has been funded by the project ISDEEC ANR-16-CE40-0013.
