Abstract  We present a grid of stellar models, obtained with the CLÉS evolutionary code, following the specification of ESTA-Task1, and the corresponding seismic properties, computed with the LOSC code. We provide a complete description of the corresponding files that will be available on the ESTA web-pages.

1 Introduction

The preparation of the CoRoT mission brought up the need of a reference grid of stellar models in order to locate the possible CoRoT targets in the Hertzsprung-Russell (HR) diagram, and to allow a first interpretation of the forthcoming CoRoT-data. For this purpose, several grids of stellar models were computed according to the ESTA-Task1 specifications. In this paper we present the grids of stellar models we computed with the code CLÉS (Scuflaire et al., 2007a), as well as the seismic properties we derived by using the adiabatic oscillation code LOSC (Scuflaire et al., 2007b) for models on the main sequence (MS) or close to it.

In sections 2 and 3 we describe, respectively, the input physics and the set of stellar parameters we used. The evolutionary tracks, stellar models and oscillation frequency data can be found on the ESTA Web site. The description of all this material is given in Sect. 4 for the evolution and structure models, and in Sect. 5 for the seismic properties of the stellar models. Finally, in Sect. 6 we summarize the type and amount of available files.

2 Input physics

For three out of four stellar model grids we adopted the reference input physics, as well as the physical and astronomical constants specified for ESTA-Task 1 comparisons (see also Sect. 5 in Lebreton et al., 2007a). We stress that these specifications do not always coincide with those of the standard version of CLÉS (see Scuflaire et al., 2007a).

– Equation of State (EoS) – OPAL 2001 equation of State (Rogers & Nayfonov, 2002) available in the OPAL Web site. The tabulated values of $C_V$ have been replaced with the values derived from the tabulated values of $P$, $\Gamma_1$, $\chi_T$, $\chi_\rho$. For each $\rho$, $T$, $X$ and $Z$ we interpolate in the tables by using our own interpolation routine.

– Opacities – OPAL96 (Iglesias & Rogers, 1996). The opacity tables used in CLÉS have been calculated on-line for the standard GN93 (Grevesse & Noels, 1993) metal mixture, and using the smoothing routine available in the OPAL Web site to build the final opacity tables. The low temperature opacity tables by Alexander & Ferguson (1994) are also smoothly added (see Scuflaire et al., 2007a), and conductive opacities were not included in these computations. As for EoS, we interpolate in $\rho$, $T$, $X$ and $Z$ by using our own interpolation routines.

– Nuclear network – We choose the same nuclear network as in model comparison, that is, basic pp chain and CNO cycle reactions up to the $^{17}\text{O}(p, \alpha)^{14}\text{N}$. We adopted the nuclear reaction rates from the analytical formulae provided by the NACRE compilation (Angulo et al., 1999), including that one for the $^{14}\text{N}(p, \gamma)^{15}\text{O}$, and the weak screening factors from Salpeter (1954). The electronic density, taking part in the screening factor computation, was estimated assuming full ionization of chemical elements.

– Chemical composition – We adopted the metal distribution provided by the Grevesse & Noels (1993) (thereafter GN93) solar mixture. Only the abundances of light elements (Li, Be and B) were modified to be consistent with those used in CESAM. The isotopic ratios are those of Anders & Grevesse (1989) except for the $^2\text{H}/^4\text{H}$ and...
Fig. 1 Theoretical HR diagram for the evolution phase comprised between the initial homogeneous model and that with a hydrogen mass fraction at the center reduced by 1% with respect to the initial model (that is, $X_c = 0.693$). Evolutionary tracks are labeled by the corresponding stellar mass. Solid lines correspond to grey models and dashed ones to models with Kurucz boundary conditions.

$^{3}\text{He}/^{4}\text{He}$ ratios for which we took those of Gautier & Morel (1997).

- **Convection** – All the evolutionary tracks were computed with the classical mixing length treatment of convection by Bohm-Vitense (1958) and the formulation of Henyey et al. (1965) for optically thin regions. The mixing length parameter $\alpha_{\text{MLT}}$ was fixed at 1.6 for all the grids. Note that the latter is the value chosen for ESTA comparisons, but it does not correspond to the value derived from a solar calibration.

- **Overshooting.** All the models, regardless of their mass, were computed without convective core overshooting.

- **Atmosphere.** ESTA–Task1 specification requires the surface boundary conditions to be provided by integration of a grey atmosphere following the Eddington’s $T(\tau)$ law (grey models, thereafter). Three of the four stellar model grids were computed following the ESTA specification, while for the fourth one, temperature and density at $T = T_{\text{eff}}$ were obtained from Kurucz’s atmosphere models (Kurucz, 1998).
3 Stellar parameters

We provide evolutionary tracks for masses from 0.8 to 8 $M_\odot$, with a mass step $\Delta M=0.1$, from 0.8 to 1.6 $M_\odot$, $\Delta M=0.2$ up to 4.0 $M_\odot$, and $\Delta M=0.5$ from 4.0 to 8.0 $M_\odot$.

The initial hydrogen mass fraction is $X=0.70$ in all grids. Three different values of the metal mass fraction $Z$ (0.02, 0.01 and 0.006) are available for grids of grey models, while only $Z=0.02$ has been considered in the grid computed with Kurucz atmosphere boundary conditions.

4 Data

4.1 Evolutionary tracks

For each stellar parameter ($M, X, Z$) we follow the PMS evolution from the Hayashi track, and the calculation ends either when the temperature at the stellar center is high enough to burn He, or when the age of the model is larger than 20 Gyr. We recall that the computation of these models does not include conductive opacities and that these ones should be taken into account in modeling low mass stars up to the helium ignition. The grids of these evolutionary tracks are
available from the ESTA Web site[4] and consist of two HRD-files, whose name contains the values of the stellar parameters for which they were computed. For instance, “m1.00Z0.02X0.70-HRD1.txt” and “m1.00Z0.02X0.70-HRD2.txt” contain the evolutionary tracks for a 1.00 $M_{\odot}$ star with initial chemical composition $X = 0.70$ and $Z = 0.02$. The first four lines in HRD1 and HRD2-files provide information about the stellar parameters and the input physics used to build the model. Since most of them have already been described in previous section, we only mention that $f_g$ and $f_t$ indicate the factor by which the mesh and time step were multiplied. Both, $f_g$ and $f_t$ were set equal to 0.5, that is, the number of mesh points and the temporal steps were doubled with respect to the standard value used in CLÉS (Scuflaire et al., 2007b). The quantities for which the temporal evolution were tabulated in the HRD files are the following:

HRD1 files:
- **Column 1** – Stellar mass in units of $M_{\odot}$.
- **Column 2** – Stellar luminosity (log$(L/L_{\odot})$).
- **Column 3** – Decimal logarithm of the effective temperature in K (log $T_{\text{eff}}$).
- **Column 4** – Stellar radius in units of solar radius ($R/R_{\odot}$).
- **Column 5** – Stellar age in Myr.
- **Column 6** – Hydrogen mass fraction at the center.
- **Column 7** – log $g$, with $g$, the surface gravity.
- **Column 8** – Number of convective-radiative boundaries.
- **Column 9** – Codification of the of boundary type: “2” for boundary from convective to radiative region and “1” for boundaries from radiative to convective one, going from the stellar center towards the surface.
- **Column 10-15** – Relative radius of the six first convective-radiative boundaries (from the center outwards).

HRD2 files:
- **Column 1** – Number of model.
- **Column 2** – Stellar age in Myr.
- **Column 3** – Stellar radius in solar radius ($R/R_{\odot}$).
- **Column 4** – Stellar luminosity in units of solar luminosity ($L/L_{\odot}$).
- **Column 5** – Effective temperature in K.
- **Column 6** – Temperature at the center in units of 10$^7$ K.
- **Column 7** – Central density $\rho_c$ in g.cm$^{-3}$.
- **Column 8** – Hydrogen mass fraction at the center ($X_c$).
- **Column 9** – Central helium mass fraction ($Y_c$).
- **Column 10** – Number of convective regions.
- **Column 11** – Relative mass of the convective core ($m_{cc}/M_*$).
- **Column 12** – Relative radius of the base of the outer convective region ($R_{cc}/R_*$).
- **Column 13** – Mass of the helium core in $M_{\odot}$. The helium core is defined by the mass of the region with a hydrogen mass fraction smaller than $10^{-2}$.

The log $T_{\text{eff}}$–log$L/L_{\odot}$ diagram for all the models with a metal mass fraction $Z = 0.02$ have been plotted in Fig. 1 for the PMS evolution, and in Fig. 2 for the MS and Post-MS evolutionary phases. For each mass there is a pair of curves, one was computed with Eddington’s law as boundary conditions at the photosphere (solid lines) and the other used Kurucz’s atmosphere models (dashed lines). It is interesting to note that, as it concerns the theoretical HR diagram, the atmosphere type affects only models with effective temperature lower than 6300 K. The effects on the seismic properties will be discussed in Sect. 5.

In Fig. 2 we marked the model locations at the middle of their MS (central hydrogen mass fraction $X_c = 0.35$) by
open circles and that of models with a central hydrogen mass fraction $X_{c} \simeq 0.001$ by filled ones. Defining the beginning of MS by the model with a central mass fraction of hydrogen decreased by 1% with respect to the initial one (that is $X_{c} = 0.693$ for the present computations), and its end by that with $X_{c} \simeq 0.001$, the MS-lifetime varies from $5 \times 10^{7}$ yrs for 8 $M_{\odot}$ to more than 13 Gyr for 0.9 $M_{\odot}$. The number of computed stellar models that span the main sequence phase of evolution is of the order of 160 for each $(M, X, Z)$.

The dependence on the stellar mass of the convective core mass, for models in the middle of MS is shown in Fig. 3 and that of the convective envelope bottom in Fig. 4. Finally, in Fig. 5 we show the mass of the He core at the end of the MS as a function of the stellar mass.

4.2 Stellar models

In addition to the evolutionary tracks, a selection of internal structure models for each $(M, X, Z)$ are also available:

- **ZAMS model** - defined as the model for which the ratio of gravitational to nuclear luminosity is lower than 2%.
- **1MS model** - as the model which has burned 1% of H ($X_{c} \simeq 0.693$).
- **MS model** - as the model with half of the initial H at the center ($X_{c} \simeq 0.35$)
- **TAMS model** - as the model with $X_{c} \simeq 0.01$
- One every five models spanning the MS phase of evolution: from $X_{c} = 0.693$ to $X_{c} = 0.001$. That means about 30 models for each set of stellar parameters.

An individual file is provided for each stellar model whose name is formed with the stellar parameters, for example:

$m1.00Z0.02X0.70-####.gong$, where “####” can be “ZAMS”, “1MS”, “MS”, “TAMS”, or a number corresponding to the number of the model. The format adopted for these files is the FGONG\footnote{Document “Description of the file formats used within ESTA/CoRoT” at http://www.astro.up.pt/corot/ntools/info.html\cite{gough1990}} one with the first twenty-five variables. The number of mesh points through the stellar interior is of the order of 2200, and 100 additional mesh points are used to describe the stellar atmosphere from an optical depth $\tau = 2/3$ outwards, up to $\tau = 10^{-3}$.

Among the physical quantities stored in FGONG files there are the mass fraction of the most important contributors to nuclear energy generation. For illustration, we show in Figs. c the chemical profile of key elements such as $^{3}$He, $^{12}$C, and $^{14}$N inside the stellar models in the mid–MS.

### 5 Seismic properties

For each equilibrium model in FGONG format, we also provide a file containing the properties of radial and non radial oscillation modes with spherical degree $\ell = 1, 2, \text{ and } 3$. These properties were computed by using the code LOSC\cite{scuflaire2007} with the standard surface boundary condition (regularity of solution when $P = 0$ at the surface, that is, $\delta P/P + (4 + \omega^{2})\delta r/r = 0$). The angular frequencies of the computed oscillation modes cover the domain given by 0.3–50 times the dynamical time ($\tau_{\text{dym}} = \sqrt{R/\dot{GM}}$).

The file name is the same as that of the equilibrium model but with the extension “.freq”; the content is the following:

- **Column 1** – spherical angular degree $\ell$.
- **Column 2** – radial order $n$.
- **Column 3** – dimensionless frequency $\omega = \sigma \cdot \tau_{\text{dym}}$.
- **Column 4** – angular frequency $\sigma$.
- **Column 5** – frequency $\nu = \sigma / 2 \pi$ in Hz.
- **Column 6** – period $P$ in seconds.
- **Column 7** – $\beta_{\text{fr}} = 1 - C_{nt}$ gives the frequency shift generated by solid rotation, where $C_{nt}$ is the Ledoux’s constant ($\text{Ledoux} [1951]$).
- **Column 8** – fraction of the kinetic energy associated to the radial component of the motion $e_{v} = E_{\text{kin}, v} / E_{\text{kin}}$.
- **Column 9** – $\chi_{m} = \langle x \rangle$ is the mean value of $x = r/R$ weighted by the kinetic energy of the oscillation mode, and determines in which region the mode is trapped.
- **Column 10** – $\Delta = 2 \sqrt{(\chi^{2} - \langle x \rangle^{2})}$, that takes values between 0 and 1, vanishes for a perfectly trapped mode.

Since discontinuities in the sound speed derivatives in the stellar interior (such as those introduced by the boundaries of the convective regions and by the second helium ionization zone) produce periodic signatures in the frequencies of low degree modes (see e.g. Gough \cite{gough1990}), we decided to provide, as well, files containing the time variations of some quantities that may be of interest in the seismic analysis of stellar models. So, for each stellar parameter set $(M, X, Z)$, but only for the MS-lifetime, we built a file whose name is...
Fig. 6 Upper panel: equilibrium abundance of $^3$He for models with masses from 0.8 to 8 $M_\odot$. Lower panel: equilibrium abundance of $^{14}$N (solid lines) and $^{12}$C (dotted lines) for each of the considered stellar masses. The thicker lines correspond to the chemical profile in a 2 $M_\odot$ model.

Fig. 7 Evolution of the cutoff frequency along the MS evolution of models with masses from 0.8 $M_\odot$ (upper curve) to 2 $M_\odot$ (lower curve).

5.1 Effect of atmospheric boundary conditions

For the chemical composition $X = 0.70$ and $Z = 0.02$ there are two types of stellar models depending on whether the boundary conditions at $T = T_{\text{eff}}$ are given by Kurucz atmosphere models or by grey ones (with Eddington’s law). We showed in Fig. 1 and 2 that the effect on the HRD location was significant only for $T_{\text{eff}} \lesssim 6300$ K. The effect on the oscillation frequencies may be, however, important even for higher temperatures. As an example we show in Fig. 8 the difference between oscillation frequencies for 1.8 $M_\odot$ models in mid-MS. The difference in the global parameters

- **Acoustic depth** in seconds of the border of the convective core (column 10) corresponding to the linear relative radius $r_{cc}/R$ given in column 9.
- **Acoustic depth** in seconds of the bottom of the convective envelope (column 12) corresponding to the linear relative radius $r_{ce}/R$ given in column 11.
- **Second He ionization region**: linear relative radius ($r_{\text{HeII}}/R$) in column 12, and the corresponding acoustic depth $\tau_{\text{HeII}}$ in column 13.

The four first lines, and the columns 1–6 are the same as in HRD2-files.

In principle, only oscillation modes with frequencies lower than the acoustic cutoff one are trapped in the stellar interior and should be observed. As an indication of the order of magnitude of the expected oscillation frequencies we show in Fig. 7 the variation with time of the cutoff frequency for models with masses smaller than 2 $M_\odot$.

---

- **Cutoff frequency** (in $\mu$Hz) at the photosphere (column 7): $\nu_{ac} = c/(4\pi H_p)$ where $c$ is the sound speed, and $H_p$ the pressure scale height.
- **Acoustic radius** in seconds (column 8): $r_{ac} = \int_0^R 1/c \, dr$ where $R$ is the stellar radius at the photosphere.
for these Eddington and Kurucz stellar models are $\Delta R/R = 4 \times 10^{-4}$, $\Delta L/L = 1.4 \times 10^{-5}$, and $\Delta X < 10^{-5}$. Nevertheless, the density at $T=T_{\text{eff}}$ provided by the two atmosphere models is different enough to affect a significant fraction of the star, leading to an important variation of the oscillation frequencies. Note that for this comparison only the subphotospheric stellar structure was considered in the computation of the oscillation frequencies. The differences at high frequency will be even larger if the atmosphere structure is included in the calculation.

6 Conclusions

In order to provide a reference grid of stellar models for the first interpretation of the CoRoT data, we have computed three sets of grey stellar models for 29 different masses from 0.8 to 8 $M_\odot$. Each grid is computed with a different chemical composition, and altogether they span metallicity values from [M/H]=−0.45 to +0.07 (taking as reference the value of Z/X=0.0245 for the Sun given by GN93). There are 3 × 29 × 3 = 261 files containing data on time evolution of global quantities, around 3050 files with the detailed stellar structure (interior and atmosphere), and other 3050 with the corresponding oscillation frequencies for low degree modes ($\ell = 0$, 1, 2, and 3). In addition, a set of stellar models with the Kurucz’s atmospheres as boundary conditions were also computed, for the same values of stellar mass, but for only one chemical composition. That means additional ~2087 files, 87 for the time evolution, and the rest of them for the stellar structure and the corresponding seismic properties.
