Transcriptional Regulation of Osteopontin Production in Rat Osteoblast-like Cells by Parathyroid Hormone

Masaki Noda and Gideon A. Rodan

Department of Bone Biology and Osteoporosis Research, Merck, Sharp, & Dohme Research Laboratories, West Point, Pennsylvania 19486

Abstract. Osteopontin (OP) or bone sialoprotein is a recently characterized extracellular matrix protein which is abundant in bone and is produced by osteoblasts. Parathyroid hormone (PTH) is a potent calcitropic hormone which regulates osteoblastic function including the synthesis of extracellular matrix proteins. This study examines the effect of human PTH (hPTH(1-34)) on the expression of this novel protein in rat osteoblast-like cells. hPTH(1-34) significantly decreased the amount of OP in culture media of the rat osteoblastic osteosarcoma cell line, ROS 17/2.8, detected by Western immunoblot analysis. hPTH(1-34) also suppressed the steady-state level of OP mRNA two- to threefold with an ED50 of \(1.3 \times 10^{-10}\) M. This inhibition was detectable at 24 h, reached its nadir at 48 h, and lasted at least up to 96 h. The hPTH(1-34) effects were mimicked by isobutylmethylxanthine, cholera toxin, 8-bromo-cAMP, forskolin, and isoproterenol. hPTH(1-34) suppressed by two- to threefold the rate of OP gene transcription, estimated by nuclear run-on assays. The suppression of OP mRNA levels by hPTH(1-34) was also seen when basal levels were increased by transforming growth factor type \(\beta\), or \(1,25\)-dihydroxyvitamin D3, or were decreased by dexamethasone. A similar decrease in the steady-state level of OP mRNA by hPTH(1-34) was also observed in primary cultures of osteoblast-enriched cells from fetal rat calvaria. These findings indicate that hPTH(1-34) suppresses the production of the novel extracellular matrix protein, OP, in osteoblasts at least in part through transcriptional control.

Osteopontin (OP) is a 44-kD glycoprotein which is rich in aspartic acid and glutamic acid and contains one phosphoserine and 12 phosphothreonine residues (Prince et al., 1987). OP is an abundant noncollagenous protein in bone (Franzen and Heinegard, 1985) and was immunohistochemically detected in bone matrix, osteoid, osteoblasts, osteocytes, preosteoblast-like cells, neurons, neurosensory cells, and the proximal convoluted tubules of the kidney (Mark et al., 1987a,b, 1988). OP messenger RNA was found in bone and kidney and at much lower levels in brain and lung (Yoon et al., 1987). In embryonic rat calvaria, OP mRNA expression was shown to increase between 15 and 21 d of gestation during development (Yoon et al., 1987). The amino acid sequence of OP predicted from a cDNA cloned from a rat osteosarcoma (ROS 17/2.8) cell library (Oldberg et al., 1986) was shown to be \(92\)% identical to that of 2ar (Nomura et al., 1988). The 2ar gene was originally isolated on the basis of its enhanced expression in the mouse JB4 epidermal cell line in response to 12-O-tetradecanoyl-phorbol-13-acetate (TPA) (Smith and Denhardt, 1987). Since 2ar appears to be the product of a single copy gene, it is probably the mouse homologue of rat OP (Nomura et al., 1988). In fact, 2ar mRNA, similar to rat OP, was expressed in mouse calvaria, vertebrae, and kidney (Nomura et al., 1988). In addition, 2ar mRNA was also expressed in placenta and decidua (Nomura et al., 1988). Although OP/2ar mRNA was expressed in cultured fibroblasts in response to TPA, neither the mRNA nor the antigen was detected in situ in rat or mouse skin (Mark et al., 1987a,b, 1988; Yoon et al., 1987; Nomura et al., 1988).

The cDNA-predicted amino acid sequence of OP contains the Arg-Gly-Asp-Ser (RGDS) motif (Oldberg et al., 1986), which is found in fibronectin and other cell-adhesion proteins, and was shown to interact with cell surface receptors (Pytel et al., 1986; Tamkun et al., 1986). OP also has high affinity to hydroxyapatite, possibly due to its nine consecutive aspartic acid residues (Oldberg et al., 1986; Prince et al., 1988). Based on these features, OP was proposed to participate in cell attachment to mineralized matrix (Oldberg et al., 1986). Indeed, OP promoted the attachment of rat osteosarcoma cells and human gingiva fibroblasts to plastic dishes, and this effect was inhibited by RGD-containing peptides (Oldberg et al., 1986; Somerman et al., 1987). The physiological function of OP is not yet known. The temporal and tissue-specific OP/2ar expression seen in vivo (Yoon et al., 1987; Nomura et al., 1988) indicates that this protein is...
restricted to bone, kidney, neural tissue, and placenta and suggests a functional role in these tissues. The steady-state level of OP mRNA or OP in osteoblast-like cells is increased by 1,25-dihydroxyvitamin D3 (Yoon et al., 1987; Prince and Butler, 1987) and is reduced by glucocorticoids (Yoon et al., 1987). 2ar mRNA in epidermal cells and fibroblasts is induced by embryonic carcinoma-derived growth factor and basic fibroblast growth factor (Nomura et al., 1988) in addition to TPA (Smith and Denhardt, 1987). We have recently shown that transforming growth factor type β (TGF-β) enhances OP gene expression through transcriptional control in the rat osteoblast-like osteosarcoma cells, ROS 17/2.8, and in newborn mouse calvaria-derived osteoblast-like cells, MC3T3E1 (Noda et al., 1988a). These observations suggest that OP/2ar expression is regulated by factors which control growth and/or differentiation.

Parathyroid hormone (PTH) has pronounced effects on the production of many extracellular matrix proteins in osteoblastic cells (Luben et al., 1976; Wong et al., 1977; Kream et al., 1980, 1986; Majeska and Rodan, 1982; Hamilton et al., 1985; Noda et al., 1988b). Moreover, target cells of PTH correspond to OP-producing cells which include proximal tubule, distal tubule, and ascending loop of Henle cells (Klahr and Hruska, 1984), in addition to osteoblasts (Rodan and Rodan, 1984). This study examined the effects of PTH on OP gene expression in the osteoblastic osteosarcoma ROS 17/2.8 cells and in primary cultures of fetal rat calvaria cells. We found that PTH inhibited OP gene expression at least in part through transcriptional control.

Materials and Methods

Human PTH (1-34) (hPTH(1-34)) was purchased from Bachem Biochemical (Torrance, CA). Percoll TGF-β1 was obtained from R&D Systems, Inc. (Minneapolis, MN). 1,25-dihydroxyvitamin D3 was a kind gift from Dr. Uskokovic at Hoffman-LaRoche (Nutley, NJ). Forskolin was purchased from Calbiochem-Bebrin Corp. (La Jolla, CA). Cholecalciferol, isotubulin, and benzamidethionine (−)isoperinol, and 6-bromo-cAMP were obtained from Sigma Chemical Co. (St. Louis, MO). Proteinase K and vanadyl ribonucleoside complex were purchased from Bethesda Research Laboratories (Gaithersburg, MD).

Culture Cell

ROS 17/2.8 cells were grown in 9.5-, 150-, or 500-cm2 Costar (Cambridge, MA) or Nunc (Roskilde, Denmark) tissue culture dishes in modified Ham's F12 medium containing 5% FBS as described previously (Majeska et al., 1985; Noda and Rodan, 1987). Fetal rat osteoblast-enriched cells (fraction 3, F3 cells) were isolated by sequential enzymatic digestion of 19 d calvaria and were grown in modified Ham's F12 media supplemented with 2% FBS and 5% horse serum as described previously (Wong and Cohn, 1974; Noda et al., 1987a). To examine the effects of PTH and other agents, the media were replaced every 24 h unless described otherwise.

Western Immunoblot Analysis

ROS 17/2.8 cells were grown to confluence in media containing 5% FBS. The cultures were then rinsed three times with PBS and were cultured in serum-free modified F12 media containing 0.1% vol/vol vehicle (0.1% acetic acid, 0.1% bovine serum albumin) or 10−7 M hPTH(1-34) for 96 h. Then the media were collected and the cells were trypsinized and counted by a Coulter counter (Coulter Electronics, Inc., Hialeah, FL). The media were centrifuged at 12,000 g for 10 min at 4°C to remove cell debris, and the supernatants were concentrated 24-fold by Centricon-10 (Amicon Corp., Danvers, MA) at 4°C according to the manufacturer's instructions. Aliquots corresponding to equal numbers of cells were incubated with 5% β-mercaptoethanol in the electrophoresis buffer and were analyzed by 10% SDS-PAGE (Laemmli, 1970). The proteins were electrophoretically transferred to nitrocellulose filters as described previously (Brumette, 1981). The antisera against rat osteopontin were described elsewhere (Mark et al., 1987b) and were kindly provided by Drs. C. W. Prince (University of Alabama, Birmingham, AL) and W. T. Butler (University of Texas Health Sciences Center, Houston, TX). The filters were incubated with the antisera and anti-rabbit IgG goat antibody conjugated with horseradish peroxidase (Bethesda Research Laboratories) followed by incubation with 4-chloro-1-napthol for color development according to the manufacturer's protocol (Bethesda Research Laboratories).

RNA Isolation

ROS 17/2.8 cells or fetal calvaria-derived osteoblast-enriched (F3) cells were grown to confluence in 150- or 500-cm2 dishes and were treated for indicated periods of time with hPTH(1-34) or other agents. Cytoplasmic RNA was extracted as described previously (Greenberg and Ziff, 1984; Noda and Rodan, 1987). Cells (2–6 × 107) were rinsed with cold PBS, scraped in PBS, and centrifuged at 500 g at 4°C. The cell pellets were resuspended in 1 ml of NP-40 lysis buffer (10 mM Tris-HCl, pH 7.4, 10 mM NaCl, 3 mM MgCl2, 0.5% vol/vol NP-40), incubated on ice for 5 min, and then spun at 500 g at 4°C for 5 min. The supernatants were mixed with vanadyl ribonucleoside complex (final concentration 10 mM), vortexed, and spun at 12,000 g at 4°C for 10 min. The supernatants were mixed with equal volume of digestion buffer (0.2 M Tris-HCl, pH 7.4, 0.44 M NaCl, 2% SDS, 25 mM EDTA) containing proteinase K (final concentration 200 µg/ml) and were incubated at 37°C for 60 min, followed by phenol/chloroform (1:1) extraction, and ethanol precipitation.

Northern Blot Analysis

Total RNA (10 or 20 µg) was subjected to electrophoresis through 1% agarose–formaldehyde (0.44 M) gel and electrophoretically transferred to nylon filters (Hybond N: Amersham Corp., Arlington Heights, IL) (Thomas, 1980). Complementary DNA probes for rat osteopontin and rat β-tubulin were kindly provided by Ors. K. Yoon (Merck, Sharp, and Dohme Research Laboratories, West Point, PA) (Yoon et al., 1987) and S. R. Farmer (Boston University, Boston, MA) (Bond et al., 1984), respectively. Rat alkaline phosphatase cDNA was described previously (Noda et al., 1987b). Rat actin cDNA was purchased from Stanford University (Palo Alto, CA).

The insert of each cDNA plasmid was purified and labeled with [α-32P]dCTP (3,000 Ci/mmol, Amersham Corp.) by using random oligonucleotide primers (Amersham Corp.) and Klenow fragments as described by Feinberg and Vogelstein (1984) to a specific activity >10 6 cpm/µg. Membranes with bound RNA were irradiated for 2 min by ultraviolet light to cross-link the RNA to the filters. Then the filters were prehybridized overnight at 42°C in 50% formamide, 5 × SSC (1× SSC = 0.15 M NaCl/15 mM Sodium Citrate), 5 × Denhardt's solution, and 200 µg/ml sonicated sperm DNA. Hybridization was carried out for 16-24 h in fresh prehybridization buffer to which each 32P-labeled probe was added at 10 6 cpm/ml. Filters were washed three times in 2 × SSC, 0.1% SDS at room temperature for 5 min each; and once in 0.1× SSC, 0.1% SDS at 65°C; and were exposed to x-ray films (Eastman Kodak Co., Rochester, NY) with intensifying screens.

In Vitro Transcription (Nuclear Run-on) Assay

Isolation of nuclei, in vitro transcription, and hybridization were carried out essentially as described previously (McKnight and Palmiter, 1979; Grou dzie et al., 1981) with minor modifications. Nuclei (2–5 × 107) were isolated by gentle homogenization of cells in a buffer containing 10 mM KC1, 10 mM Tris-HCl, pH 7.4, 1.5 mM MgCl2, 0.25% vol/vol NP-40. The isolated nuclei were incubated at 25°C for 20 min in a buffer containing 50 mM Tris-HCl, pH 7.4, 100 mM ammonium sulfate, 1.8 mM dithiothreitol, 1.8 mM MnCl2, 80 U RNasin, 0.3 µm each ATP, GTP, and CTP, and 100 µCi of [α-32P]UTP (800 Ci/mmol, Amersham Corp.) followed by sequential digestions with DNase I and proteinase K. RNA was extracted by phenol/chloroform and was ethanol precipitated. After centrifugation at 12,000 g for 10 min, the pellets were dissolved in 6 M guanidium hydrochloride followed by addition of 0.5 vol ethanol, and were reprecipitated at −20°C overnight. After centrifugation at 12,000 g for 10 min at 4°C, the pellets were rinsed with cold 80% ethanol, dried, and resuspended in TE
Figure 1. PTH inhibition of the OP production in culture media of ROS 17/2.8 cells. Confluent cells in 150-cm² dishes were treated with 10^{-7} M hPTH-(1-34) for 96 h in serum-free media. Media were concentrated by Centricon-10 and aliquots were examined by Western immunoblot analysis as described in Materials and Methods. Molecular masses in kilodaltons and the position of OP are indicated. C, control; P, PTH-treated culture. The figure represents one of two similar experiments.

Results

The treatment of cells with 10^{-7} M hPTH(1-34) for 96 h greatly reduced OP levels in culture media, estimated by Western immunoblot analysis (Fig. 1). The specificity of the immunoblot analysis with the same antisera has previously been demonstrated (Noda et al., 1988a). Mobility of OP on SDS-PAGE was reported to depend on acrylamide concentration (45 kD in 15% and 75 kD in 5-15% gradient gels) (Prince et al., 1987). In 10% gels, OP migrated as a 60-kD band (Fig. 1).

hPTH(1-34) treatment also decreased the steady-state level of OP mRNA. This effect was dose-dependent between 10^{-11} M and 10^{-4} M, which reduced OP mRNA levels by about threefold. The half-maximal effect dose (ED₅₀) was ∼3 × 10^{-9} M (Fig. 2, A and B). Actin mRNA on the same filter was used as control (Fig. 2 C). The reduction of the steady-state level of OP mRNA produced by hPTH(1-34) was first detected at 24 h, reached its nadir at 48 h, and remained at that level at least up to 96 h (Fig. 3).

PTH stimulates adenylate cyclase in both osteoblast-like osteosarcoma (ROS 17/2.8) cells and primary cultures of osteoblast-enriched fetal rat calvaria cells (Majeska and Rodan, 1982; Rodan and Rodan, 1984). To test whether the PTH effect on OP mRNA was related to cAMP, ROS 17/2.8 cells were treated with 1 mM isobutylmethylxanthine, 0.3 μg/ml cholera toxin, 0.5 mM 8-bromo-cAMP, 10 μM forskolin, or 1 μM (-)-isoproterenol. Treatment of each with these agents for 48 h reduced the steady-state level of OP mRNA at least as much as 10^{-7} M hPTH(1-34) (Fig. 4). Isobutylmethylxanthine was the most potent inhibitor in this series. Alkaline phosphatase mRNA level was also reduced by these agents. β-Tubulin mRNA, used as control, was unchanged.

To study the mechanism for PTH regulation of OP mRNA, we examined the effect of 10^{-7} M hPTH(1-34) on the transcriptional rate of the OP gene by in vitro nuclear transcription (run-on) assays and found it to be reduced by about threefold (Fig. 5). In the same experiment, the transcriptional rate of the β-actin gene, which served as the control, was not affected by hPTH(1-34) (Fig. 5). Treatment with 0.3 μg/ml cholera toxin also showed a similar suppression in the rate of OP gene transcription (data not shown).

Other factors which modulate OP gene expression include TGF-β which enhances the expression at least in part through transcriptional regulation (Noda et al., 1988a), dexamethasone which decreases OP mRNA levels, and 1,25-dihydroxyvitamin D₃ which also increases OP mRNA levels (Yoon et al., 1987). The combined effects of hPTH(1-34) and each of these agents on OP mRNA accumulation are shown in Fig. 6. When the cells were treated with saturation doses of...
hPTH(1–34) (10⁻⁷ M) and TGF-β (4 ng/ml), the steady-state OP mRNA levels were similar to control. Together with a saturation dose of dexamethasone (10⁻⁷ M), hPTH(1–34) (10⁻⁷ M) caused further suppression of OP mRNA levels. 1,25-dihydroxyvitamin D₃ (10⁻³ M) increased OP mRNA about tenfold and hPTH(1–34) (10⁻⁷ M) partially inhibited this increase. As previously reported (Noda and Rodan, 1987), alkaline phosphatase mRNA level was increased by TGF-β and hPTH(1–34) also suppressed this effect.

PTH effect on osteopontin mRNA in osteoblast-like cells was also tested in osteoblast-enriched primary cultures of fetal rat calvaria (F3) cells. Fig. 7 shows that the effect of hPTH(1–34) (10⁻³ M) on OP mRNA levels in fetal rat calvaria (F3) cells was similar to that on ROS 17/2.8 cells, indicating that PTH has this effect not only in osteoblastic osteosarcoma cells but also in nontransformed osteoblastic cells.

Discussion

The reduction in the rate of OP gene transcription by PTH indicates that PTH regulates OP expression at least in part via transcriptional control. The degree of the PTH effects on the steady-state levels of OP mRNA was similar to that on the rate of OP gene transcription. Preliminary studies also indicated that PTH had no significant effect on OP mRNA stability (data not shown). Taken together, these results suggest that transcriptional control is possibly the major regulatory pathway for PTH action on OP gene expression. PTH stimulates cAMP accumulation in ROS 17/2.8 cells, osteoblast-enriched fetal rat calvaria cells, and most target cells. The effects of cAMP-elevating agents and cAMP analogue on OP mRNA were very similar to those of PTH, suggesting the possible involvement of cAMP in this PTH action on OP expression. cAMP mediation has previously been implicated in the transcriptional control of genes encoding human proencephalin, human prolactin, corticotropin-releasing factor, and somatostatin (Cooke et al., 1981; Shibahara et al., 1983; Shen and Rutter, 1984; Comb et al., 1986). These genes contain short homologous cis-regulatory elements in their 5' flanking regions, the deletion of which abolishes modulation by cAMP (Comb et al., 1986). The data presented here suggest the presence of cAMP-responsive negative control element(s) in the regulatory region of the OP gene. cis-Regulatory elements which share the structure of the consensus sequence have been shown to mediate both positive and negative effects of glucocorticoid. The pathway(s) leading
from cAMP elevation to gene regulation have not been elucidated. The cis-regulatory elements presumably interact with proteinaceous factors (Maniatis et al., 1987) which could be modulated by protein kinase A phosphorylation. A similar scheme was proposed for the regulation of collagenase gene promoter by TPA via protein kinase C phosphorylation of proteinaceous factors (Maniatis et al., 1987) which could be dated. The AP-1 (Angel et al., 1987).

In various cell types OP/2αr mRNA expression is stimulated by several other agents which modulate cell growth, including steroid hormone (Yoon et al., 1987; Prince and Butler, 1987) and peptide growth factors (Smith and Denhardt, 1981; Kream et al., 1986) and of alkaline phosphatase (Luben et al., 1976; Wong et al., 1977; Majeska and Rodan, 1982) synthesis. The similar response of OP to PTH strengthens the relationship of this novel protein to the osteoblastic phenotype. Certain osteoblastic products such as plasminogen activator (Hamilton et al., 1985) and collagenase (Sakamoto and Sakamoto, 1986) are increased by PTH. However, these proteins may be involved in bone resorption and may participate in the catabolic effects of this hormone (Luben et al., 1976; Wong et al., 1977; Majeska and Rodan, 1982). In contrast, TGF-β, a possible anabolic agent on bone, enhances the expression of collagen (Centrella et al., 1987; Canalis et al., 1988), alkaline phosphatase (Harrod et al., 1985; Noda and Rodan, 1987; Pfeilschifter et al., 1987), and osteopontin (Noda et al., 1988a) in osteoblastic cells, thus having opposite effects to those of PTH. The TGF-β effects are probably not mediated by cAMP (Insogna et al., 1987). Further study will be necessary to elucidate the molecular details of these regulatory pathways.

Extrapolation of these findings to the in vivo situation remains to be established. The expression of OP and OP mRNA have been consistently observed in osteoblasts and bones in vivo in both rat (Yoon et al., 1987; Mark et al., 1987a,b, 1988) and mouse (Nomura et al., 1988). This study suggests that OP expression would be reduced by PTH as part of its catabolic effects on bone.

We are indebted to Drs. William T. Butler and Charles W. Prince for the use of rat osteopontin and antisera. We are also grateful to Drs. Kyonggeun Yoon and Stephen R. Farmer for the rat osteopontin and the tubulin cDNA clones, Drs. John Harrison and Barbara Kream for their advice regarding the nuclear run-on assay, and to Ms. Dianne McDonald and Jeannie Arizin for their help in preparing this manuscript.

Received for publication 26 August 1988.
