The production of acute phase cytokines, interleukin 6 (IL-6), tumour necrosis factor (TNFα) and interleukin 1 (IL-1β), was studied in primary cultures of human skin fibroblasts, human monocytic cell line U937 and primary cultures of human umbilical vein endothelial cells (HUVEC) after in vitro infection with vaccinia virus. Significant increase in IL-6 mRNA followed by enhanced protein secretion into the culture media was found in fibroblasts, U937 cells, and HUVEC. TNFα increased production in vaccinia virus infected U937 cells resembled closely the pattern of IL-6 production observed in the infected cells. Transient increase in NF-κB binding activity was found in the infected U937 (at 90 min) and endothelial (at 30 min) cells. Vaccinia virus induced cytokine production appeared to be transcriptional.

**Key words:** Vaccinia virus, Acute phase cytokines, Fibroblasts, U937, HUVEC

### Introduction

Vaccinia virus (Vv) belongs to the poxviruses superfamily, a group of large DNA viruses known from their exclusive propagation within the cytoplasm of eukaryotic cells. VV infections are commonly associated with a generalized host cell protein and nucleic acids synthesis inhibition. The shut down of host transcriptional and translational machineries is done in favour of selective expression of viral genes. However, several groups of eukaryotic proteins are transiently induced by many viruses in infected cells, e.g. cytokines (TNFα, IL-6, INFγ), heat shock proteins (mouse hsp72) and transcription factors (NF-κB).

Viral infections are accompanied by dysregulation of cytokine production and virus-cytokine interactions appear to be complex as cytokines by themselves possess pleiotropic activities. Induction of a cytokine, a cytokine receptor or a growth factor production by a virus could stimulate its own replication and infectious virus production (like IL-8 for HCMV). Some cytokines might also help to escape immune responses if a cytokine exerts a negative effect on the immune system (like Epstein-Barr virus encoded IL-10, typical antiflammatory cytokine). Therefore, reduction of proinflammatory cytokines production, like IL-1 and TNFα, having not only direct antiviral effect (like TNFα) but also coordinating the host inflammatory and immune responses to viral infection, could lead to viral infection progression.

DNA viruses like vaccinia and other orthopoxviruses, possessing large genomes, acquired anticytokine defense mechanisms encompassing expression of soluble cytokine receptor genes and cytokine converting enzymes. Thus, virus encoded several cytokine response modifiers (like crmA) act together to inhibit the release of proinflammatory cytokines in response to infection.

To further understand the biology of vaccinia virus and virally induced acute phase response, acute phase inflammatory cytokines were measured in three infected human cell types: primary cultures of skin fibroblasts, the promonocytic cell line U937 and umbilical vein endothelial cells.

### Materials and Methods

#### Cells and viruses

The WR strain of vaccinia virus was propagated on Vero cells infected at multiplicity of infection (MOI) 1:1 (one plague forming unit per cell), maintained in MEM supplemented with 4% heat-inactivated FCS. Infected cells were harvested at maximum cytopathic effect and infectivity estimated by quantal infectivity assay on Vero cells.

Human skin fibroblasts were cultured in MEM containing 10% FCS, 2 mM glutamine and antibiotic-antimycotic mixture (passage 3–12 was used). For RNA extraction cells were grown in 84 mm diameter culture dishes in the density of 1.8 × 10^6 cells/dish in...
MEM with 5% FCS. As a positive control of cytokine production, LPS (lipopolysaccharide from *Escherichia coli* 026:B6, Sigma) in concentration 1 μg/ml and IL-1α (10 ng/ml) were used.

U937 cells were grown in RPMI supplemented with 8% FCS and antibiotics. The experiments were carried out on U937 cells differentiated into a macrophage-like cells in the presence of 50 nM phorbol myristate acetate (PMA) for 24–36 h. Adherent cells (in RPMI with 4% FCS without PMA) were infected or treated with LPS for an additional 6–24 h.

Endothelial cells were isolated from human umbilical cord veins. Umbilical veins from individual cords were cannulated, washed with HBSS without Ca and Mg and filled with 0.1% collagenase type I in HBSS with Ca and Mg. After a 15-min incubation at 37°C, the detached cells were collected and washed by three times repeated centrifugation and resuspended in M199 containing 20% heat-inactivated FCS, heparin (10 U/ml), HEPES (15 mM), 1% gentamycin and endothelial cell growth supplement (ECGS) (50 μg/ml). Cells from passages 2 to 4 were grown on 5% gelatin precoated 60-mm culture dishes.

All cultures were infected with vaccinia virus at MOI 1:1, 2:1 or 4:1 (as indicated in the figure legends) at the time of LPS addition. Mock infected (control) cultures were prepared in the same way. Infected cells were washed after 1-h virus adsorption and fresh medium added. Effectiveness of infection was routinely checked by microscopic examination at 24 h postinfection (p.i.) and typical rounding of infected cells was observed. Higher infectious doses than the doses used would result in profound cytopathic effect at 24–48 h.

The viability of the cells was routinely checked using fluorescein diacetate/ethidium bromide double fluorescent test.

**Cytokine assay**

TNFα, IL-1β and IL-6 proteins were determined in culture media using commercially available ELISA kits (Genzyme).

Statistical significance of the differences between means was estimated using Fisher-Behrens tests.

**RNA extraction and northern blot analysis**

Total RNA was extracted from cultured cells using standard phenol-chloroform method and LiCl precipitation.13 RNA samples (10 μg) were separated electrophoretically in 1% agarose gel under denaturing conditions.14 RNA was then transferred to hybond-N membranes (Amersham, UK). The blots were baked at 80°C for 2 h and prehybridized 1–3 h. Specific mRNAs were detected by hybridization at 68°C in 10% dextran sulfate, 1 M NaCl and 1% SDS with 1.2 kb EcoRI–HindIII fragment of human IL-6 cDNA (kindly donated by Dr T. Kishimoto), or 1.1 kb PstI fragment of human TNFα (ATCC, Rockville, MD) labelled with 32P-dCTP by random priming.

**Reverse transcriptase-PCR**

cDNA synthesis reactions were done in a total volume of 20 μl containing 10 μl of each RNA sample (0.5 or 1 μg), 0.5 μg oligo(dT)12–18 primer (Gibco) and 200 U of SuperScript™ III RNase H Reverse Transcriptase (Gibco) according to the protocol provided with the enzyme. PCRs were set up in a total volume of 50 μl containing 5 μl of the cDNA, 0.2 mM deoxynucleoside triphosphate, 0.5 μM of each oligonucleotide primer, 50 mM KCl, 1.5 mM MgCl2, and 2.5 U of Taq polymerase (Gibco). PCRs were run on 0.5 ml tubes, in Omunix thermal cycler (Hybaid, Teddington, UK) equipped with heated lid. Reactions were carried out at the following conditions: 94°C for 1 min, 60°C for 1 min, and 72°C for 1.5 min: for 35 cycles (IL-6, TNF-α), or 94°C for 1 min, 55°C for 1 min, and 72°C for 1.5 min for 35 cycles (β-actin). Each thermal profile was ended with final extension at 72°C for 10 min. The reaction products were then resolved on nondenaturing 2% agarose (Sigma, St Louis, MO) gel and visualized by staining with ethidium bromide.

The following PCR primers were custom-synthesized by Gibco:

TNFα (sense) 5'-ATGAGCCTGAAGGACATGTC-3';

(anti) 5'-GCAATGATCCAAATGAGCTGCCC-3';

IL6 (sense) 5'-CTTTTGAGTTGGAGGTTACCTAG-3';

(anti) 5'-GCTGCGCCAGATGATGAGTTGTC-3';

β-actin (sense) 5'-AGCGGGAAATCGTGCGTG-3';

(anti) 5'-GGGTACATGGTGGTGCCG-3'.

All primers were designed to match sequences in separate exons to avoid the contribution of genome templated product in the analysed signal. The expected product lengths are: 702 bp for TNFα, 237 bp for IL6 and 307 bp for β-actin.

**Electrophoretic mobility shift assay**

Nuclear extracts were prepared from vaccinia virus infected U937 cells and HUVEC by using the method of Suzuki et al.15 Protein concentrations were determined by bichinchonic method (Sigma) according to manufacturer’s instruction.
DNA mobility shift assay was carried out as described by Duyao et al. A double stranded oligonucleotide 5'-AAGTCCGGGTTTTCCCCAACC3' containing two repeats of NF-kB binding site, corresponding to -1101 to -1081 bp region of murine c-myc was synthesized by Molecular and Macromolecular Research Center, Lodz, Poland. The DNA probe was end-labelled by using polynucleotide kinase and γ-32P-ATP. Equal amounts of protein (5 μg) in 10% glycerol were incubated at room temperature for 30 min with 0.5 ng (~10^5 cpm) of the labelled dsDNA oligonucleotide in the presence of 4 μg of poly(dl-dC) in 10 mM Tris pH 7.5, 50 mM NaCl, 1 mM EDTA and 0.1 mM DTT in a total volume of 25 μl. Some samples were incubated in the presence of 100-fold molar excess of specific cold oligonucleotide probe as a competitor. Incubation mixtures were electrophoresed on 4.5% non-denaturing polyacrylamide gel in 0.5 × TBE. The dried gels were analysed by autoradiography.

Results

Vaccinia virus infection induces transcription and secretion of IL-6 in human fibroblasts

Supernatants of infected human skin fibroblasts and uninfected control fibroblasts were collected and IL-6 measured by ELISA, while the cells were used for total RNA extraction. The representative experiment illustrated in Fig. 1A shows that vaccinia virus induced IL-6 mRNA was detected only early post-infection (at 4 h) and the transcript is not found after 6–48 h p.i. Despite this early message degradation, IL-6 protein was detected in the culture media at all times p.i. and even at 48 h the cytokine was further increased by the virus (Fig. 1B). Quantification of IL-6 showed that amounts of IL-6 induced by LPS and lower doses of VV (MOI of 1:1 and 2:1) were comparable, however much higher infectious dose (MOI of 4:1) caused larger increase in cytokine production than after LPS addition (Fig. 2A). While primary cultures of human skin fibroblasts failed to produce detectable amounts of TNFα, IL-1β was induced by LPS and VV as well as by combination of LPS and VV (Fig. 2B). No basal IL-1β expression level was found in control cultures. Almost synergistic effect of the combination of stimulants was found only for IL-1β (Fig. 2B), since IL-6 induction was not further induced by LPS and VV (Fig. 2A).
Vaccinia virus infected human monocytic cell line U937 produces increased TNFα and IL-6.

PMA differentiated U937 cells produced increasing amounts of TNFα and IL-6 mRNAs as well as the proteins as estimated by RT-PCR and ELISA (Fig. 3A,B, C). The cytokine was not detectable in fibroblast and HUVEC cultures. Although IL-6 accumulation was still enhanced at 24 h, the cytokine transcripts were already decreased probably due to destability of the mRNA by the virus. Increased IL-6 mRNA content found in 24 h control cultures seems to result from the culture conditions. Similar changes were observed in case of IL-1β and IL-12 mRNAs in vaccinia virus infected U937 cells, while no change in IL-10 mRNA was found in virally infected cells (data not shown).

Human endothelium exhibits early change in IL-6 production

Vaccinia virus infected human umbilical vein endothelial cells exhibit increased levels of IL-6 mRNA at 2 h (Fig. 4A) and moderate IL-6 protein stimulation (statistically not significant) found at 6 h (Fig. 4B). Thus, the production of IL-6 in primary cultures of endothelial cells is stimulated by the virus earlier than in two other cell types. NF-κB early activation in VV-infected HUVEC (30 min–Fig. 5B) supports the latter observation. Vaccinia virus caused similar early increase in DNA binding activity in U937 cells (Fig. 5A).

Discussion

Proinflammatory cytokines play an important role in modulating the pathogenesis of viral infections.9,17 Pleiotropic cytokines, like TNFα, IL-1β and IL-6, have been established as potent inducers of an inflammatory response with fever, acute phase protein synthesis in the liver and cofactors of T and B lymphocyte and macrophage activation.18 Little is known about the regulatory role played by the cytokines in vaccinia virus infection. Since genetically engineered poxviruses are widely used for recombinant gene expression and vaccination,19 therefore its pathogenesis in human tissues is of potential interest. In this study, the capacity of three types of human cell lines to produce acute phase cytokines following vaccinia virus infection, was tested.

Fibroblasts, that do not classically belong to the immune system, produce IL-6 and IL-1 that can influence the local and systemic reactions observed during host defense against viral infections. Increased production of IL-6 and IL-1β found in the infected cells in culture (Figs 1 and 2), suggests that the cytokines may play an important role in the pathogenesis of VV. Excessive amounts of IL-1β produced by human skin fibroblasts during vaccinia virus infection could be bound with high affinity by the VV IL-1β...
receptor encoded by gene B15R in the Western Reserve (WR) strain. However, no mechanism for IL-6 neutralization was found in vaccinia virus so far.

Amongst its pleiotropic effects, TNFα possesses a remarkable antiviral activity and the ability to kill virus-infected cells. On the other hand, a role for TNF in activation of human immunodeficiency virus replication was found. In our studies, vaccinia virus induced profound increase in TNFα production only in the monocytic cell line U937 (Fig. 3A and B), whereas no detectable levels of the cytokine were found in fibroblasts and endothelial cells. Our results demonstrate that vaccinia virus induce TNFα transcriptionally, although translational control of TNF production was found by others. Cowpox virus encoded soluble TNF receptor (crmC) is able to

FIG. 4. Effect of vaccinia virus infection on IL-6 expression in human endothelial cells. IL-6 mRNA was measured for 6 and 24 h samples by hybridization with human cDNA probe giving also unspecific signal with 18S rRNA. Additionally, 2, 4 and 6 h RNA samples were analysed by RT-PCR (A). The cytokine protein was determined by ELISA in the culture media from three separate experiments and expressed in ng/ml of medium and 10^6 cells. Vaccinia virus infection was at MOI 2:1. LPS-stimulated cultures were used as the positive control. p.i.–post infection; p.s.–post stimulation. Results are expressed as the mean ± standard deviation. Statistically significant results and P values < 0.01 are marked by *.

FIG. 5. Vaccinia virus inducible NF-κB binding activity in U937 and HUVEC. Double-stranded oligonucleotide comprising NF-κB site was incubated with nuclear extracts isolated from control (C) and vaccinia virus (V) infected U937 cells (MOI 1:1) (A) or HUVEC (MOI 2:1) (B). V*–100-fold excess of unlabelled dsDNA oligonucleotide added as a competitor. Specific complexes and free probes are indicated.
inhibit host-elicited TNF. The stimulatory effect of VV on the cytokine production places vaccinia virus in the group of other TNFα inducers. However, other viruses, e.g., EBV, inhibit TNF transcription.

Three other cytokines were preliminary estimated in infected monocytes by RTPCR: IL-12, IL-1β and IL-10. IL-1β and IL-12 both act as proinflammatory cytokines and additionally IL-12 promotes Th1-dependent resistance to infections by different agents. On the other hand, IL-10, known from its suppressing effect on cytokine production by HIV-infected macrophages and T cells, was not induced in U937 cells by VV at mRNA level (our unpublished data). Thus, vaccinia virus infection in monocytes seems to elicit mainly proinflammatory cytokines, like, IL-1, TNFα and IL-12.

Endothelial cells play a key role in viral tropism in vivo as they are directly exposed to the circulating blood. Vaccinia virus infection of primary cultures of endothelial cells showed very early up-regulation of specific transcripts (at 2 h) followed by an increase in IL-6 secretion at 6 h (Fig. 4), therefore it is suggested that endothelial cells are more susceptible to vaccinia virus infection than fibroblasts and monocytic cell line in which the effect of similar infectious doses of the virus was delayed.

Transcription factor NF-κB is crucial in activating the transcription of genes encoding proinflammatory cytokines, therefore vaccinia virus induced IL-6 and TNFα production can be in part explained by rapid increase in IFN-κB DNA binding activity found in U937 and HUVEC (Fig. 5), and this is the first report on VV effects on the transcription factor binding.

Since this is in vitro study, it would be difficult to relate the results of our studies directly to vaccinia virus infection in vivo. When a virus induces moderate amounts of cytokines, it may be beneficial by eliciting an immediate antiviral response, but it may cause adverse effects when cytokine release is highly elevated by bacterial products (LPS). Our data (Fig. 2) suggest that the well-known severe manifestations of combined virus-bacterial infections may be due, at least in part, to an enhanced release of the endogenous pyrogens TNFα and IL-1 which both may lead upon introduction into circulation to an inflammatory response with high fever, shock syndromes, and tissue damage.
