Affine and projective tree metric theorems

Aaron Kleinman, Matan Harel and Lior Pachter

Abstract. The tree metric theorem provides a combinatorial four point condition that characterizes dissimilarity maps derived from pairwise compatible split systems. A related weaker four point condition characterizes dissimilarity maps derived from circular split systems known as Kalmanson metrics. The tree metric theorem was first discovered in the context of phylogenetics and forms the basis of many tree reconstruction algorithms, whereas Kalmanson metrics were first considered by computer scientists, and are notable in that they are a non-trivial class of metrics for which the traveling salesman problem is tractable.

We present a unifying framework for these theorems based on combinatorial structures that are used for graph planarity testing. These are (projective) PC-trees, and their affine analogs, PQ-trees. In the projective case, we generalize a number of concepts from clustering theory, including hierarchies, pyramids, ultrametrics and Robinsonian matrices, and the theorems that relate them. As with tree metrics and ultrametrics, the link between PC-trees and PQ-trees is established via the Gromov product.

Keywords. hierarchy, Gromov product, Kalmanson metric, Robinsonian metric, PC tree, PQ tree, phylogenetics, pyramid, ultrametric.

1. Introduction

In his “Notebook B: Transmutation of Species” (1837), Charles Darwin drew a single figure to illustrate the shared ancestry of extant species (Figure 1). That figure is a pictorial depiction of a graph known as a rooted X-tree.

Definition 1. An X-tree \( \mathcal{T} = (T, \phi) \) is a pair where \( T = (V, E) \) is a tree and \( \phi : X \to V \) is a bijection from \( X \) to the leaves of \( T \). Two X-trees \( \mathcal{T}_1 = (T_1, \phi_1) \), \( \mathcal{T}_2 = (T_2, \phi_2) \) are isomorphic if there exists a graph isomorphism \( \Phi : T_1 \to T_2 \)

We thank Laxmi Parida for introducing us to the applications of PQ trees in biology during a visit to UC Berkeley in 2008. Thanks also to an anonymous reviewer whose careful reading of an initial draft of the paper helped us greatly. AK was funded by an NSF graduate research fellowship.
such that $\phi_2 = \Phi \circ \phi_1$. A **rooted $X$-tree** is an $X$-tree with a distinguished vertex $r$.

The biological interpretation of rooted $X$-trees lies in the identification of the leaves with extant species, and the vertices along a path from a leaf to the root as ancestral species. Although the validity of trees in describing the ancestry of species has been debated [19], trees are now used to describe the shared ancestry of individual nucleotides in genomes and they are perfectly suited for that purpose [8].

In phylogenetics, it is desirable to associate lengths with the edges of trees. Such lengths may correspond to time (in years), or to the number of mutations (usually an estimate based on a statistical model). This leads to the notion of a tree metric, that is conveniently understood via the notion of a weighted split system. Here and in what follows, for simplicity we often take $X = \{1, 2, \ldots, n\}$.

**Definition 2.** A split $S$ of $X$ is a partition $A \mid B$ of $X$ into two nonempty subsets. The corresponding **split pseudometric** is given by

$$D_S(i, j) = \begin{cases} 1 & \text{if } |\{i, j\} \cap A| = 1, \\ 0 & \text{otherwise.} \end{cases}$$

A split $A \mid B$ is **trivial** if $|A| = 1$ or $|B| = 1$. A **split system** is a set of splits containing all the trivial splits.
Removing an edge of an $X$-tree disconnects the tree into two pieces and thus gives a split $S_e$ of $X$. We can associate a split system $\{S_e | e \in E(T)\}$ to $T$ by doing this for each edge.

**Definition 3.** A dissimilarity map is a function $D : X \times X \rightarrow \mathbb{R}_{\geq 0}$ such that $D(i, i) = 0$ and $D(i, j) = D(j, i)$ $\forall i, j \in X$. A dissimilarity map $D$ is $S$-additive if there is a split system $S$ such that

$$D = \sum_{S \in S} w(S)D_S$$

for some non-negative weighting function $w : S \rightarrow \mathbb{R}_{\geq 0}$. If $S$ is the split system associated to an $X$-tree $T$, we say $D$ is $T$-additive. $D$ is a tree metric if it is $T$-additive for some $X$-tree.

The following classic theorem precisely characterizes metrics that come from trees:

**Theorem 1.** A dissimilarity map $D$ is a tree metric if and only if for each $i, j, k, l \in X$, the value

$$\max\{D(i, j) + D(k, l), D(i, k) + D(j, l), D(i, l) + D(j, k)\} \quad (1)$$

is realized by at least two of the three terms.

Equation 1 is called the four-point condition. Theorem 1 motivates the development of algorithms for identifying tree metrics that closely approximate dissimilarity maps obtained from biological data. In molecular evolution, dissimilarity maps are derived by determining distances between DNA sequences according to probabilistic models of evolution; more generally, algorithms that approximate dissimilarity maps by tree metrics can be applied to any distance matrices derived from data. However, dissimilarity maps derived from data are never exact tree metrics due to two reasons: first, as discussed above, some evolutionary mechanisms may not be realizable on trees; second, even in cases where evolution is described well by a tree, finite sample sizes and random processes underlying evolution lead to small deviations from “treeness” in the data.

It is therefore desirable to generalize the notion of a tree, and a natural approach is to consider adding splits to those associated with an $X$-tree. One natural class of split systems to consider is the following.

**Definition 4.** A circular ordering $\mathcal{C} = \{x_1, \ldots, x_n\}$ is a bijection between $X$ and the vertices of a convex $n$-gon $P_n$ such that $x_i$ and $x_{i+1}$ map to adjacent vertices of $P_n$ (where $x_{n+1} := x_1$). Let $S_{i,j}$ denote the split $\{x_i, x_{i+1}, \ldots, x_{j-1}\} | \{x_j, x_{j+1}, \ldots, x_{i-1}\}$ and let $S(\mathcal{C}) = \{S_{i,j} | i < j\}$. We say a split $S$ is circular with respect to a circular ordering $\mathcal{C}$ if $S \in S(\mathcal{C})$, and a split system $S$ is circular if $S \subseteq S(\mathcal{C})$ for some circular ordering $\mathcal{C}$.

Given a set $\mathcal{E}$ of circular orderings, let $S(\mathcal{E}) = \cap_{\mathcal{C} \in \mathcal{E}} S(\mathcal{C})$ be the system of splits that are circular with respect to each ordering in $\mathcal{E}$. The split system associated with a binary $X$-tree arises in this way from a family $\mathcal{E}$...
of $2^{n-2}$ circular orderings [26], and a tree metric is obtained by associating non-negative weights to each split in the system. *Kalmanson metrics*, which were first introduced in the study of traveling salesmen problems where they provide a class of metrics for which the optimal tour can be identified in polynomial time [21], correspond to the case when $|E| = 1$.

Kalmanson metrics can be visualized using *split networks* [19]. We do not provide a definition in this paper, but show an example in Figure 2 (drawn using the software SplitsTree4). The neighbor-net [3] and MC-net [13]

\[
\begin{array}{cccccccc}
A & B & C & D & E & F & G \\
A & 0 & 32 & 17 & 77 & 39 & 86 & 39 \\
B & 32 & 0 & 34 & 77 & 21 & 86 & 39 \\
C & 17 & 34 & 0 & 66 & 46 & 75 & 46 \\
D & 77 & 77 & 66 & 0 & 84 & 13 & 50 \\
E & 39 & 21 & 46 & 84 & 0 & 93 & 46 \\
F & 86 & 86 & 75 & 13 & 93 & 0 & 59 \\
G & 39 & 39 & 46 & 50 & 46 & 59 & 0 \\
\end{array}
\]

![Figure 2. A Kalmanson metric (left) visualized as a split network (right).](image)

algorithms provide a way to construct circular split systems from dissimilarity maps, but despite having a number of useful properties [4, 22], have not been widely adopted in the phylogenetics community. This is likely because split networks (such as in Figure 2) fail to reveal the “treeness” of the data. More specifically, the internal nodes of the split network do not correspond to meaningful “ancestors” as do the internal nodes in $X$-trees. Other approaches to visualizing “treeness”, e.g. [29], do reveal the extent of signal conflicting with a tree in data, but do not reveal in detail the splits underlying the discordance.

We propose that PQ- and PC-trees, first developed in the context of the consecutive ones problem [2, 18] and for graph planarity testing [27, 17], are convenient structures that interpolate between $X$-trees and full circular
split systems. The main result of this paper is Theorem 3. Given a Kalman-
son metric, the theorem shows how to construct a “best-fit” PC-tree which
realizes the metric and captures the “treeness” of it.

Another (expository) goal of this paper is to organize existing results
on PC-trees, their cousins PQ-trees, and corresponding metrics (Theorem 4
in Section 5). We believe this is the first paper to present the various results
as part of a single unified framework. As a prelude, we illustrate the types of
results we derive using a classic theorem relating rooted $X$-trees to special
set systems that encode information about shared ancestry.

**Definition 5.** A hierarchy $\mathcal{H}$ over a set $X$ is a collection of subsets of $X$ such that

1. $X \in \mathcal{H}$, and $\{x\} \in \mathcal{H}$ for all $x \in X$
2. $A \cap B \in \{\emptyset, A, B\}$ for all $A, B \in \mathcal{H}$.

The requirement that each $\{x\} \in \mathcal{H}$ is not part of the usual definition
of hierarchy but its inclusion here will simplify later results. We then have
the following:

**Proposition 1.** There is a natural bijection between hierarchies over $X$ and
rooted $X$-trees.

Proposition 1, which we will prove constructively in Section 2, is an ele-
mentary but classic result and has been discovered repeatedly in a variety of
contexts [12, 16]. For example, in computer science, hierarchies are known as
laminar families where they play an important role in the development of re-
cursive algorithms represented by rooted trees (see, e.g. [14]). Hierarchies are
also important because they are the combinatorial structures that underlie
ultrametrics.

**Definition 6.** An ultrametric is a symmetric function $D : X \times X \to \mathbb{R}$ such that

$$D(x, y) \leq \max\{D(x, z), D(y, z)\} \quad \forall x, y, z \in X$$

**Definition 7.** An indexed hierarchy is a hierarchy $\mathcal{H}$ with a non-negative
function $f : \mathcal{H} \to \mathbb{R}_{\geq 0}$ such that for all $A, B \in \mathcal{H}$, $A \subset B \Rightarrow f(A) \leq f(B)$.

The extension of Proposition 1 to metrics, proved in [20], shows that
these objects are the same. The proposition is an instance of a tree metric
theorem that associates a class of combinatorial objects (in this case rooted
$X$-trees) with a class of metrics (in this case ultrametrics). Our results or-
ganize other tree metric theorems that have been discovered (in some cases
independently and multiple times) in the contexts of biology, mathematics
and computer science.

In particular, we investigate relaxations of Definitions 1, 3 and 5 for
which there exist analogies of Theorem 1 and Proposition 1. For example,
hierarchies are special cases of pyramids [9], which can be indexed to produce
strong Robinsonian matrices [24]. Proposition 10 (originally proved in [9])
states that these objects correspond to each other mimicking the correspondence between hierarchies and ultrametrics.

In discussing tree metric theorems we adopt the nomenclature of Andreas Dress who distinguishes two types of objects and theorems: the affine and the projective \cite{10}. Roughly speaking, these correspond to “rooted” and “unrooted” statements respectively, and we use these terms interchangeably. For example, a hierarchy is an affine concept whose projective analog is a pairwise compatible split system. Similarly, unrooted $X$-trees are the projective equivalents of rooted $X$-trees, and tree metrics are the projective equivalents of ultrametrics. We’ll see that Kalmanson metrics are to tree metrics as Robinsonian matrices \cite{24} are to ultrametrics, and circular split systems are to pairwise compatible split systems as pyramids are to hierarchies. We use PQ-trees \cite{2} and their projective analogs PC-trees \cite{27} to link all of these results.

2. Hierarchies, $X$-trees and split systems

We begin by proving Proposition 1, both for completeness and to introduce some of the notation that we use. An $X$-tree $T = (V,E,\phi)$ has a natural partial ordering on its vertices: for distinct $u,v \in V$, we say $u \preceq v$ if $v$ lies on the unique path from $u$ to the root. Given $v \in V$, let $H_v = \{x \in X | x \preceq v\}$ and $\alpha(T) = \{H_v | v \in V\}$.

Proposition 2. The map $\alpha$ is a bijection from rooted $X$-trees to hierarchies over $X$.

Proof. Let $(T,\phi)$ be a rooted $X$-tree with root $r$. $H_r = X$ and $H_{\phi(x)} = \{x\}$ for all $x \in X$, so $H$ satisfies (1) of Definition 5. Consider any two $H_u, H_v \in \alpha(T)$. If $u \preceq v$ then $H_u \cap H_v = H_u$, if $v \preceq u$ then $H_u \cap H_v = H_v$, and otherwise $H_u \cap H_v = \emptyset$. So each pair of elements in $\alpha(T)$ satisfies (2) of Definition 5 and $\alpha(T)$ is a hierarchy.

For the reverse direction, let $H$ be a hierarchy over $X$. Let $T = (V,E)$ be the digraph with $V = \{v_A | A \in H\}$ and with edges denoting minimal inclusion: $T$ has an edge from $v_B$ to $v_A$ iff $A \subset B$ and there does not exist $C \in H$ such that $A \subsetneq C \subsetneq B$. We will show that $T$ is a tree. First note that by induction on $|C|$ each vertex $v_C$ with $C \neq X$ is connected to $v_X$ and has at least one parent. Now suppose $v_A, v_B$ are distinct parents of $v_C$. Then $A \cap B \neq \emptyset$, so without loss of generality by the hierarchy condition $A \subset B$. But then $C \subset A \subset B$, a contradiction. Thus $T$ is connected and has one fewer edge than vertices, so $T$ is a tree with root $v_X$. Define the map $\phi : X \rightarrow V$ by $\phi_{\{x\}} = v_x$. This is a bijection from $X$ to the leaves, so $T = (T,\phi)$ is a rooted $X$-tree with $\alpha(T) = H$. \qed

The above proposition gives a characterization of rooted $X$-trees in terms of collections of subsets of $X$. We turn now to the projective analogue of rooted $X$-trees.
Definition 8. Two $X$-splits $A_1|B_1, A_2|B_2$ are compatible if one of $A_1 \cap A_2, A_1 \cap B_2, B_1 \cap A_2, B_1 \cap B_2$ is empty, and are incompatible otherwise.

Removing an edge $e$ from a projective $X$-tree disconnects the tree into two pieces and thus gives an $X$-split $S_e$. Let $\beta(T) = \{S_e| e \in E(T)\}$. It is easy to check that $\beta(T)$ is a pairwise compatible split system, and a basic theorem of $X$-trees [5, 23] shows every pairwise compatible split system arises in this way, giving

**Proposition 3.** $\beta$ is a bijection from the set of projective $X$-trees to the set of pairwise compatible split systems over $X$.

Finally we show that pairwise compatible split systems and hierarchies are in bijection. Fix $r \in X$ and let $S$ be a set of pairwise compatible splits of $X$. The unrooting map $\gamma_r$ sends a split $S$ to the component of $S$ that does not contain $r$. The rooting map $\delta_r$ sends a set $A \subseteq X \setminus \{r\}$ to the split $\delta_r(A) = X \setminus X \setminus A$. If $S$ is a split system, let $\gamma_r(S) = \{\gamma_r(S)|S \in S\}$.

**Proposition 4.** $S$ is a pairwise compatible split system over $X$ if and only if $\gamma_r(S)$ is a hierarchy over $X \setminus \{r\}$.

**Proof.** Choose $S_1, S_2 \in S$, with $S_i = A_i|B_i$. If $S_1, S_2$ are compatible, then without loss of generality $A_1 \cap A_2 = \emptyset$. If $r \in B_1, B_2$, then $\gamma_r(S_i) = A_i$, so $\gamma_r(S_1) \cap \gamma_r(S_2) = \emptyset$. If $r \in A_1$, then $r \notin A_2$ since $A_1 \cap A_2 = \emptyset$, and therefore $r \in B_2$. In this case $\gamma_r(S_1) = X \setminus A_1$ and $\gamma_r(S_2) = A_2$, so $\gamma_r(S_1) \cap \gamma_r(S_2) = A_2 = \gamma_r(S_2)$, again satisfying the hierarchy condition. The final case follows by symmetry. Conversely, suppose $\gamma_r(S)$ is a hierarchy. Then for any two $S_1, S_2 \in S$ we have $\gamma_r(S_1) \cap \gamma_r(S_2) \in \{\emptyset, \gamma_r(S_1), \gamma_r(S_2)\}$. Checking the cases as above shows that $S_1$ and $S_2$ must then be compatible splits.

We define the map $\kappa_r$ to take an affine $X \setminus \{r\}$-tree $T$ to the projective $X$-tree obtained by attaching a vertex with label $r$ to the root of $T$. The inverse map $\lambda_r$ takes a projective $X$-tree $T$ to the affine $X$-tree as follows: let $v$ be the vertex of $T$ labelled $r$. Then $\lambda_r(T)$ is obtained by rooting at the neighbor of $v$, and then deleting $v$.

**Proposition 5.** If $AT$ and $H$ are the sets of all affine trees and hierarchies over $X \setminus \{r\}$, respectively, and $PT$ and $PSS$ are the sets of all projective trees and pairwise compatible split systems over $X$, respectively, then the following diagram commutes:

\[ \begin{array}{ccc} AT & \xrightarrow{\kappa_r} & PT \\ \downarrow{\alpha} & & \uparrow{\beta} \\ H & \xleftarrow{\gamma_r} & PSS \end{array} \]

Each arrow is a bijection; the unlabelled arrows are the inverses of the maps going in the other direction.
3. PQ-trees

We start our generalization of Proposition 5 with a generalization of rooted $X$-trees.

**Definition 9.** A *PQ-tree* over $X$ is a rooted $X$-tree in which every vertex comes equipped with a linear ordering on its children. Every internal vertex of degree three or less is labeled a P-vertex, and every internal vertex of degree four or more is labeled either as a P-vertex or a Q-vertex. We say two PQ-trees $T_1, T_2$ are equivalent (we write $T_1 \sim T_2$) if one can be obtained from the other by a series of moves consisting of:

1. Permuting the ordering on the children of a P-vertex,
2. Reversing the ordering on the children of a Q-vertex.

We draw a PQ-tree by representing P-vertices as circles and Q-vertices as squares, and ordering the children of a vertex from left to right as per the corresponding linear order (see Figure 3). For any PQ-tree $T$ over $X$, define the *frontier* of the tree as the linear ordering on $X$ derived from reading the leaves of $T$ from left to right. Let $\text{con}(T) = \{\text{frontier}(T')|T' \sim T\}$ be the set of all linear orderings $\prec$ that are consistent with the PQ structure of $T$. We say $I$ is an *interval* with respect to $\prec$ if there exist $a, b \in X$ such that $I = \{t|a \preceq t \preceq b\}$. Define $\alpha$ to be the map that sends the PQ-tree $T$ to

**Figure 3.** Four PQ trees. $T_1, T_2$ and $T_3$ are equivalent to each other but $T_4$ is different from the other three.
the set of all $I \subseteq X$ such that $I$ is an interval with respect to every linear ordering in $\text{con}(A)$.

**Lemma 1.** $\alpha(T)$ is a hierarchy if and only if every vertex of $T$ is a $P$-vertex. If so, let $T'$ be the corresponding normal affine $X$-tree. Then $\alpha(T) = \alpha(T')$, where $\alpha(T')$ is the hierarchy constructed in Proposition 2.

**Proof.** Let $v$ be an internal vertex of $T$, $\{c_1, c_2, \ldots, c_n\}$ the set of its children, and recall $H_v = \{x \in X | v_x \leq v\}$ is the set of all the elements $x$ such that the path from $v_x$ to the root includes $v$. Now $H_{c_1} \cup \cdots \cup H_{c_n}$ is in $\alpha(T)$, and if every vertex of $A$ is a $P$-vertex then every element of $\alpha(T)$ will be of this form. In this case $\alpha(T)$ is identical to the hierarchy constructed in Proposition 2. Now suppose $T$ has a $Q$-vertex $v$. Then $n \geq 3$ and both $A = H_{c_1} \cup H_{c_2}$ and $B = H_{c_2} \cup H_{c_3}$ are in $\alpha(T)$, but $A \cap B = H_{c_2}$ is nonempty, so $\alpha(T)$ is not a hierarchy. \[\square\]

This shows that the map $\alpha$ on PQ-trees agrees with the $\alpha$ in Proposition 6. It also shows that the usual affine $X$-trees are precisely PQ-trees with all $P$-vertices. Since PQ-trees do not necessarily give rise to hierarchies, we seek a different combinatorial characterization of them.

**Definition 10.** A collection of subsets $P$ of $X$ is a prepyramid if

1. $X \in P$ and $\{x\} \in P$ for all $x \in X$,
2. There exists a linear ordering $\prec$ on $X$ such that every $A \in P$ is an interval with respect to $\prec$.

$P$ is a pyramid if, in addition, it is closed under intersection.

If $T$ is a PQ-tree then $\alpha(T)$ is a prepyramid with respect to any $\prec \in \text{frontier}(T)$, and $\alpha(T)$ is the associated prepyramid.

**Definition 11.** Two subsets $A, B$ of $X$ are compatible if $A \cap B \in \{\emptyset, A, B\}$. Otherwise they are incompatible. A rooted family over $X$ is a collection of sets $F$ such that if $A, B \in F$ are incompatible, then $A \cap B, A \setminus B, B \setminus A,$ and $A \cup B$ are in $F$.

We are now ready to state the main result of this section.

**Proposition 6.** The map $\alpha$ is a bijection from PQ-trees to prepyramids that are rooted families.

**Proof.** If $T$ is a PQ-tree, $\alpha(T)$ is obviously a prepyramid. We now show it is also a rooted family. Trivially $X \in \alpha(T)$ and $\{x\} \in \alpha(T)$ for all $x \in X$. Let $A, B$ be incompatible sets in $F$ and $\prec \in \text{con}(A)$ a linear ordering. We can write $A = \{t | x_A \leq t \leq y_A\}$ and $B = \{t | x_B \leq t \leq y_B\}$ for some $x_A, x_B, y_A, y_B \in X$, and by incompatibility we can assume $x_A \prec x_B \leq y_A \prec y_B$. Then $A \cap B = \{t | x_B \leq t \leq y_A\}$, $A \cup B = \{t | x_A \leq t \leq y_B\}$, $A \setminus B = \{t | x_A \leq t \prec x_B\}$ and $B \setminus A = \{t | y_A \prec t \leq y_B\}$. Since each of these four sets is an interval with respect to $\prec$ for every $\prec \in \text{con}(A)$ they are each in $\alpha(T)$.

It remains to show that if $F$ is a collection of subsets of $X$ which is a prepyramid and a rooted family, then there exists a unique PQ-tree $T$ such...
that \( \alpha(T) = \mathcal{F} \). Let \( \mathcal{F}' \subseteq \mathcal{F} \) consist of the sets in \( \mathcal{F} \) that are compatible with all of \( \mathcal{F} \). Then the elements of \( \mathcal{F}' \) are pairwise compatible, so \( \mathcal{F}' \) is a hierarchy and corresponds to a tree \( T' \), as in Proposition 2. Consider the vertices \( v_C \) in \( T' \) corresponding to subsets of the form \( C = A \cup B \) with \( A, B \in \mathcal{F} \) incompatible, and mark those vertices as \( Q \)-vertices. For each such \( v_C \) there is a natural ordering on its children \( v_{C_1}, v_{C_2}, \ldots, v_{C_n} \) as follows: \( v_{C_i} < v_{C_j} \) if the labels of the leaves in the subtree rooted at \( v_{C_i} \) are all \( \prec \) the labels of the leaves of the subtree rooted at \( v_{C_j} \), where \( \prec \) is the order from the rooted family condition. Ordering the children of the \( Q \)-vertices of \( T' \) in this way, we obtain a \( PQ \)-tree \( T \).

We will use induction on \( |\mathcal{F}| \) to show \( \alpha(T) = \mathcal{F} \) and that \( T \) is the only such \( PQ \)-tree for which this is true. First, suppose \( \mathcal{F}' \) contains a set \( A \neq X \), \( |A| > 1 \). Define \( \mathcal{F}_1 = \{ C \in \mathcal{F} | A \subseteq C \text{ or } A \cap C = \emptyset \} \) and \( \mathcal{F}_2 = \{ C \in \mathcal{F} | A \supseteq C \} \). \( \mathcal{F}_1 \cap \mathcal{F}_2 = A \), and because \( A \) is compatible with everything \( \mathcal{F}_1 \cup \mathcal{F}_2 = \mathcal{F} \). \( \mathcal{F}_1 \) is a prepyramid over \((X \setminus A) \cup \{A\}\) and \( \mathcal{F}_2 \) is a prepyramid over \( A \), and both are rooted families with \( |F_i| < |\mathcal{F}| \). Then the inductive hypothesis shows there are \( PQ \)-trees \( T_1, T_2 \) such that \( \alpha(T_i) = \mathcal{F}_i \) for \( i = 1, 2 \). Now \( T_1 \) has a leaf corresponding to \( A \), and the root of \( T_2 \) also corresponds to \( A \). Grafting \( T_2 \) onto the leaf \( A \) in \( T_1 \) gives a \( PQ \)-tree \( T \) with \( \alpha(T) = \alpha(T_1) \cup \alpha(T_2) = \mathcal{F} \). Conversely, if \( T \) is a \( PQ \)-tree with \( \alpha(T) = \mathcal{F} \), \( T \) must have a node \( v \) such that the subtree \( T_1 \) with root \( v \) satisfies \( \alpha(T_1) = \mathcal{F}_1 \), and the tree \( T_2 \) obtained by replacing the subtree \( T_1 \) with the vertex \( v \) and label \( A \) gives \( \alpha(T_2) = \mathcal{F}_2 \). The inductive hypothesis gives the uniqueness of \( T_1 \) and \( T_2 \), which in turn implies the uniqueness of \( T \).

Now suppose no such set \( A \) exists, so \( \mathcal{F}' = \{ \{x_1\}, \ldots, \{x_n\}, X \} \). If \( \mathcal{F} = \mathcal{F}' \) then \( \mathcal{F} \) is a hierarchy and the \( PQ \)-tree of depth one with root a \( P \)-vertex is the unique tree such that \( \alpha(T) = \mathcal{F} \). We now consider the final case, where \( \mathcal{F} \) contains sets other than \( X \) and the \( \{x\} \)s, and every element in \( \mathcal{F} \) except for these is incompatible with another element of \( \mathcal{F} \). Without loss of generality assume \( x_1 \prec x_2 \prec \cdots \prec x_n \), where \( \prec \) is the ordering under which \( \mathcal{F} \) is a prepyramid. Then every element of \( \mathcal{F} \) is of the form \( x_{[i:j]} := \{x_i, x_{i+1}, \ldots, x_j\} \) for \( 1 \leq i \leq j \leq n \). Let \( T \) be the \( PQ \)-tree of depth 1 with a \( Q \)-vertex root and children \( x_i \). Since \( \alpha(T) = \{x_{[i:j]} | 1 \leq i \leq j \leq n\} \) it’s clear \( \alpha(T) \supseteq \mathcal{F} \).

We must show \( \mathcal{F} = \alpha(T) \), or equivalently, that \( x_{[i:j]} \in \mathcal{F} \) for all \( i < j \). We will prove this by induction on \( n \). It’s obvious for \( n = 3 \), so suppose \( n \geq 4 \). Let \( A \neq X \) be a set in \( \mathcal{F} \) that is maximal under inclusion. By assumption \( |A| > 1 \) and \( A \) is incompatible with some \( B \in \mathcal{F} \). By the rooted family condition \( A \cup B \in \mathcal{F} \) so we must have \( A \cup B = X \) by the maximality of \( A \). Without loss of generality we may write \( A = x_{[1:j]} \) and \( B = x_{[i:n]} \) with \( i \leq j \). We claim \( j = n - 1 \). For by the rooted family condition \( \mathcal{F} \) contains \( A \setminus B = x_{[1:i]} \), \( A \cap B = x_{[i:j]} \) and \( B \setminus A = x_{[j+1:n]} \). If \( j \neq n - 1 \), \( B \setminus A \) is incompatible with some other set \( C \in \mathcal{F} \). \( C \) must be of the form \( C = x_{[k_1:k_2]} \) with \( k_1 < j + 1 \leq k_2 < n \). If \( k_1 = 1 \) then \( C \supset A \) contradicting the maximality of \( A \). Then \( k_1 \neq 1 \), so \( A \) and \( C \) are incompatible and \( A \cup C = x_{[1:k_2]} \in \mathcal{F} \),
contradicting the maximality of $A$. Thus $j = n - 1$ and $x[i:n-1] \in \mathcal{F}$. By the same reasoning, $x[2:n] \in \mathcal{F}$.

Now let $\mathcal{G} = \{A \in \mathcal{F} | A \subseteq x[1:n-1]\}$. Since $x[1:n-1] \in \mathcal{G}$, $\mathcal{G}$ is a prepyramid over $X \setminus \{x_n\}$. It is also a rooted family. We claim that every element $A \in \mathcal{G}$ with $A \neq \{x_i\}, A \neq X \setminus \{x_n\}$ is incompatible with some other element of $\mathcal{G}$. To see this, write $A = x[i:j], j \leq n - 1$ and suppose $j \neq n - 1$. By our initial assumption $A$ is incompatible with some set $B = x[i':j'] \in \mathcal{F}$. If $j' \neq n$ then $B \in \mathcal{G}$ gives the incompatible set. Otherwise $B$ and $x[1:n-1]$ are incompatible, so $B \cap x[1:n-1] = x[i':n-1]$ is in $\mathcal{G}$ and is incompatible with $A$. Finally, suppose $j = n - 1$. Then $A$ is incompatible with $x[n-1:n]$, so $A \cup x[n-1:n] = x[i:n] \in \mathcal{F}$. This must be incompatible with some other set $B \in \mathcal{F}$. We can write $B = x[i':j'], i \leq j' \leq n - 1$, so $B \in \mathcal{G}$ is incompatible with $A$ and the claim is proved.

It follows that $\mathcal{G}$ is a rooted prepyramid over $X \setminus \{x_n\}$, and every element in $\mathcal{G}$ other than $X$ and the $\{x_i\}$s is incompatible with some other element of $\mathcal{G}$. By our inductive hypothesis, $x[i:j] \in \mathcal{G}$ for each $1 \leq i \leq j \leq n - 1$. We showed that $x[n-1:n] \in \mathcal{F}$, and for each $i$ the sets $x[i:n-1]$ and $x[n-1:n]$ are incompatible, so their union $x[i:n]$ is in $\mathcal{F}$. Thus $\mathcal{F} = \{x[i:j] | 1 \leq i \leq j \leq n\}$. \qed

4. PC-trees

We now describe the projective equivalent of PQ-trees.

**Definition 12.** A PC-tree over $X$ is an $X$-tree where each internal vertex comes equipped with a circular ordering of its neighbors. Additionally, each internal vertex of degree less than 4 is labelled a P-vertex, and each other vertex is labelled either a P-vertex or a C-vertex (Figure 4). Two PC-trees $\mathcal{T}_1, \mathcal{T}_2$ are said to be equivalent (we write $\mathcal{T}_1 \sim \mathcal{T}_2$) if one can be obtained from the other by a series of the following moves:

1. Permuting the circular ordering of the neighbors of a P-vertex,
2. Reversing the circular ordering on the neighbors of a C-vertex.

For a PC-tree $\mathcal{T}$, let $\text{frontier}(\mathcal{T})$ be the circular ordering given by reading the taxa in either a clockwise or counterclockwise direction. Let $\text{con}(\mathcal{T}) = \{\text{frontier}(\mathcal{T}') | \mathcal{T}' \sim \mathcal{T}\}$ and let $\beta(\mathcal{T}) = \cap_{C \in \text{con}(\mathcal{T})} S(C)$. We say $\beta(\mathcal{T})$ is the circular split system associated to $\mathcal{T}$.

**Definition 13.** A split system $\mathcal{S}$ is an unrooted split family over $X$ if, for each pair of incompatible splits $S_1 = A_1 | B_1, S_2 = A_2 | B_2$ in $\mathcal{S}$, the splits $A_1 \cap A_2 | B_1 \cup B_2, A_1 \cap B_2 | A_2 \cup B_1, A_2 \cap B_1 | A_1 \cup B_2,$ and $B_1 \cap B_2 | A_1 \cup A_2$ are all in $\mathcal{S}$ as well.

Following the proof in Proposition 6 that $\alpha(\mathcal{T})$ is a rooted family for every PQ-tree $\mathcal{T}$, one can show $\beta(\mathcal{T})$ is an unrooted family for every PC-tree $\mathcal{T}$.

**Lemma 2.** For any PC-tree $\mathcal{T}$, $\beta(\mathcal{T})$ is an unrooted split family.
Figure 4. Four PC-trees. $T_1, T_2$ and $T_3$ are equivalent to each other but $T_4$ is different from the other three.

We now generalize the map $\gamma_r$ to PQ- and PC-trees.

**Definition 14.** The **unrooting map** $\kappa_r$ sends a PQ-tree $T$ over $X \setminus \{r\}$ to the PC-tree $\kappa_r(T)$ as follows: attach a vertex labelled $r$ to the root of $T$. If vertex $v$ in $T$ has children $\{v_1, v_2, \ldots, v_k\}$ with linear ordering $v_1 < v_2 < \ldots < v_k$ and parent $w$, in $\kappa_r(T)$ the vertex has the same neighbors with circular ordering $\{v_1, \ldots, v_k, w\}$.

The **rooting map** $\lambda_r$ sends a PC-tree $T$ over $X$ to the PQ-tree over $X \setminus \{r\}$ obtained by rooting at the vertex adjacent to $r$, deleting $r$, and replacing each $C$ vertex with a $Q$ vertex. Let $v$ be such a vertex with a circular ordering $C = \{v_1, \ldots, v_m\}$; we may assume the path from $v$ to the root passes through $v_m$. Then in $\lambda_r(T)$, vertex $v$ has parent $v_m$ and children $v_1, \ldots, v_{m-1}$ with linear ordering $v_1 < v_2 < \ldots < v_{m-1}$.

Since $\kappa_r$ and $\lambda_r$ are inverses, this immediately gives the following:

**Proposition 7.** $\kappa_r$ is a bijection from PQ-trees over $X \setminus \{r\}$ to PC-trees over $X$. 
Recall that if $S$ is a split of $X$, the map $\gamma_r$ takes $S$ to the component of $S$ not containing $r$.

**Proposition 8.** Let $CUF$ be the set of circular split systems that are unrooted families over $X$, and let $PP$ be the set of prepyramids that are rooted families over $X \setminus \{r\}$. Then the map $\gamma_r$ is a bijection from $CUF$ to $PP$.

**Proof.** $\delta_r$ and $\gamma_r$ are inverses, so it suffices to show that $\gamma_r(CUF) \subseteq PRF$ and $\delta_r(PRF) \subseteq CUF$. Let $S$ be a circular unrooted split family with circular ordering $\{x_1, \ldots, x_n\}$ and suppose $r = x_i$. Then $\gamma_r(S)$ is a prepyramid with respect to the linear ordering on $X \setminus \{r\}$ given by $x_{i+1} < x_{i+2} < \cdots < x_{i-1}$.

Next, consider $S \in CUF$ and two incompatible sets $G, H \in \gamma_r(S)$, with $G = \gamma_r(S_1)$ and $H = \gamma_r(S_2)$. Assume $S_1 = A_1 \mid B_1$, $S_2 = A_2 \mid B_2$ are compatible as split systems with $A_1 \cap A_2 = \emptyset$. If $r \in A_1$, then $r \in B_2$ and $G \cap H = (X - A_1) \cap A_2 = A_2 = H$, contradicting the incompatibility of $G$ and $H$. The other cases produce similar contradictions, so $S_1$ and $S_2$ must be incompatible as split systems. Then the splits $A_1 \cap A_2, B_1 \cup B_2, A_1 \cap B_1, A_2 \cap B_1, A_1 \cup B_2$ and $B_1 \cap B_2, A_1 \cup A_2$ are all in $S$. Assume without loss of generality that $G = A_1, H = A_2$. Then $\gamma_r(\{A_1 \cap A_2, B_1 \cup B_2\}) = A_1 \cap A_2 = G \cap H \in \gamma_r(S)$, and similarly $G \cap H, G \setminus H, H \setminus G$ are all in $\gamma_r(S)$, so $\gamma_r(S)$ is a rooted family.

Conversely, let $F$ be a pyramidal, rooted family over $X \setminus \{r\}$ with linear ordering $\prec$. $\delta_r(F)$ is circular and contains all the trivial splits, as $\{x\} \mid X \setminus \{x\} = \gamma_r(\{x\})$ and $\{r\} \mid X \setminus \{r\} = \gamma_r(X \setminus \{r\})$. The above argument reverses to show $\delta_r(G), \delta_r(H) \in \delta_r(F)$ are incompatible as split systems only if $G$ and $H$ are incompatible as sets. In this case $\delta_r(G \cap H), \delta_r(G \cup H), \delta_r(G \setminus H)$ and $\delta_r(H \setminus G)$ are in $\delta_r(F)$ so $\delta_r(F)$ is an unrooted family. Thus, $\delta_r(PRF) = CUF$ and $\gamma_r(CUF) = PRF$ as required. \qed

The above propositions combine to show that the map $\kappa_r \circ \alpha^{-1} \circ \gamma_r$ is a bijection from circular split systems to PC-trees, and that in fact for a PC-tree $T$, $\kappa_r \circ \alpha^{-1} \circ \gamma_r(T)$ is precisely the split system arising from $T$ in the natural way. An example is shown in Figure 5. We thus have:

**Proposition 9.** The following diagram commutes:

$$
\begin{array}{ccc}
PQ & \xleftarrow{\kappa_r} & PC \\
\alpha & & \beta \\
\downarrow & & \downarrow \\
PRF & \xrightarrow{\gamma_r} & CUF
\end{array}
$$

where $PQ$ is the set of PQ-trees over $X \setminus \{r\}$, $PRF$ is the set of prepyramids that are rooted families over $X \setminus \{r\}$, $PC$ is the set of PC-trees over $X$, and $CUF$ is the set of circular unrooted families over $X$. 

5. Metrics Realized By PC-trees

In this section we extend the tree metric theorem (Theorem 1) by showing how to replace affine and projective trees with PQ- and PC-trees. To explain our approach, we recall that in Section 2 we reviewed the connection between trees and their representations as hierarchies and split systems:
This correspondence can be extended to metrics as follows [25]:

\[
\begin{array}{c}
AT \xy (0,0)*+{\llap{\llap{$\kappa$}}}$; (0,-15)*+{\llap{\llap{$\alpha$}}}$; (15,0)*+{\llap{\llap{$\lambda$}}}$; (0,-15)*+{\llap{\llap{$\beta$}}}$; (15,0)*+{\llap{\llap{$\gamma$}}}$; (0,-15)*+{\llap{\llap{$\delta$}}}$; (15,0)*+{\llap{\llap{$\eta$}}}$;
\end{array}
\]

Here \( U \) are ultrametrics and \( TM \) are tree metrics. The tree metric theorem is proved by diagram chasing: starting with a tree metric, the Gromov product is applied (see Definition 16 below), resulting in an ultrametric. A (unique) hierarchy representing the ultrametric can be obtained and then the PSS corresponding to the hierarchy can be derived by the unrooting map \( \delta_r \). This weighted PSS represents the tree metric.

In this section we construct a PC-tree that best realizes a Kalmanson metric by a similar approach, constructing an analog of the above diagram with suitable PQ- and PC-tree counterparts (Theorem 4). The extension requires some care, because the weighted PC-trees representing a Kalmanson metric may require extra zero splits. A key result (Theorem 3) is that there is a unique PC-tree that minimally represents any Kalmanson metric.

We begin by making precise the notion of a Kalmanson metric.

**Definition 15.** A dissimilarity map \( D \) is **Kalmanson** if there is a circular ordering \( \{x_1, \ldots, x_n\} \) such that for all \( i < j < k < l \),

\[
\max\{D(x_i, x_j) + D(x_k, x_l), D(x_i, x_k) + D(x_j, x_l)\} \leq D(x_i, x_k) + D(x_j, x_l).
\]

Let \( T \) be a projective \( X \)-tree and \( C \) a circular ordering obtained by reading the taxa of \( T \) clockwise. If \( D \) is \( T \)-additive then \( D \) is Kalmanson with respect to \( C \). Additionally, in this case one actually has equality in (2) for each \( i < j < k < l \). Kalmanson metrics are thus generalizations of tree metrics obtained by relaxing the equality conditions of the four-point theorem. The following theorem, proved in [6], gives the Kalmanson metric equivalent of the four-point condition.

**Theorem 2.** A metric \( D \) satisfies the Kalmanson condition if and only if there exists a circular split system \( S \) and weight function \( w : S \to \mathbb{R}^+ \) such that \( D = \sum_{S \in S} w(S)D_S \). If it does, the decomposition is unique.

**Proof.** Suppose \( D = \sum_{S \in S} w(S)D_S \) for some split system \( S \) that is compatible with respect to a circular ordering \( C = \{x_1, x_2, \ldots, x_n\} \). Choose \( i < j < k < l \)
and \( S = A|B \in S \). One can check that

\[
D_S(x_i, x_k) + D_S(x_j, x_l) - D_S(x_i, x_j) - D_S(x_k, x_l) = \begin{cases} 
2 & x_i, x_j \in A, x_k, x_l \in B, \\
0 & \text{otherwise}. 
\end{cases}
\]

so \( D \) satisfies the Kalmanson condition.

Conversely, assume \( D \) is Kalmanson with respect to the circular ordering \( \{x_1, \ldots, x_n\} \). Define

\[
2\alpha(i, j) = D(x_i, x_j) + D(x_{i-1}, x_{j-1}) - D(x_i, x_{j-1}) - D(x_{i-1}, x_j).
\]

The Kalmanson condition shows this is non-negative.

Recall that \( S_{i,j} := \{x_i, x_{i+1}, \ldots, x_{j-1}\}\{x_j, x_{j+1}, \ldots, x_{i-1}\} \). The system \( S = \{S_{i,j}\}_{i<j} \) is clearly circular. We claim

\[
D = \sum_{i<j} \alpha(i, j)D_{S_{i,j}}.
\]

To see this, rewrite the right hand side of (4), expanding the \( \alpha(i, j) \) and grouping together the coefficients of each \( D(x_i, x_j) \). This gives \( D = \sum_{i<j} D(x_i, x_j)c_{i,j} \) with

\[
2c_{i,j} = D_{S_{i,j}} + D_{S_{i+1,j+1}} - D_{S_{i+1,j}} - D_{S_{i,j+1}}.
\]

Now \( c_{i,j}(x_k, x_l) = \delta_{ik}\delta_{jl} \). This proves the correctness of (4) and thus shows that \( D \) comes from a weighted circular split system.

For a circular ordering \( C \) there are \( \binom{n}{2} \) splits in \( S \) and by \( (5) \) the dimension of metrics that are Kalmanson with respect to \( C \) is also \( \binom{n}{2} \), so for a fixed circular ordering the weighting is unique. Now suppose \( D \) is Kalmanson with respect to two distinct circular orderings \( C_1, C_2 \). Let \( S_i \) be the split system given by \( C_i \), and consider the decomposition \( D = \sum_{k<l} \alpha(k,l)D_{S_{k,l}} \) with respect to \( C_1 \). If \( S_{i,j} \) is circular with respect to \( C_1 \) but not with respect to \( C_2 \), then without loss of generality there exists some \( k, l \) with \( i < k < j < l \) such that \( \{x_i, x_k, x_j, x_l\} \) is cyclic with respect to \( C_1 \) and \( \{x_i, x_j, x_k, x_l\} \) is cyclic with respect to \( C_2 \). This implies

\[
D(x_i, x_j) + D(x_k, x_l) \geq D(x_i, x_k) + D(x_j, x_l) \geq D(x_i, x_j) + D(x_k, x_l),
\]

where the first inequality comes from the Kalmanson condition on \( C_1 \) and the second comes from the Kalmanson condition on \( C_2 \). So we have equality, and by \( (3) \),

\[
0 = D(x_i, x_j) + D(x_k, x_l) - D(x_i, x_k) - D(x_k, x_l) = 2 \sum_{S = A|B \in S} \sum_{i \in A, j \in B} w(S) \geq w(S_{i,j}),
\]

where the inequality follows since \( S_{i,j} \) is in the summand. So \( \alpha(i, j) = w(S_{i,j}) = 0 \), and the only nonzero terms in the decomposition of \( D \) with respect to \( C_1 \) correspond to splits in \( S_1 \) which are also splits in \( S_2 \). This
shows the decomposition of $D$ is unique, and thus the map $\nu$ from weighted circular split systems to Kalmanson metrics given by

$$\nu(S, w)(x, y) = \sum_{S \in \mathcal{S}} w(S)D_S(x, y)$$

is a bijection. □

Let $\xi = \nu^{-1}$ be the map that takes a Kalmanson metric to the weighted circular split system that describes it, and let $D$ be Kalmanson with $\xi(D) = (S, w)$. We want to find a PC-tree $T$ such that $\beta(T) = S$ as this would provide a nice encapsulation of the “treeness” of our metric, but by Proposition 9 such a tree exists if and only if $S$ is an unrooted family, which is not necessarily the case. There is, however, a canonical best choice.

**Theorem 3.** Let $D$ be a Kalmanson metric. There is a unique PC-tree $T$ and weighting function $w : \beta(T) \to \mathbb{R}_{\geq 0}$ such that the weighted circular split system $(\beta(T), w)$ gives rise to $D$, and such that the number of zero weights $|\{S \in \beta(T) | w(S) = 0\}|$ is minimal.

**Proof.** Define the closure map $\iota : S \to \bar{S}$, where $\bar{S}$ is constructed via the following algorithm:

\[
\bar{S} \leftarrow S
\text{ while } \bar{S} \text{ contains a pair of incompatible splits } A_1|B_1, A_2|B_2 \text{ do}
\]

\[
\bar{S} \leftarrow \bar{S} \cup \{ A_1 \cap A_2 | B_1 \cup B_2, A_1 \cap B_2 | A_2 \cup B_1, A_2 \cap B_1 | A_1 \cup B_2, B_1 \cap B_2 | A_1 \cup A_2 \}
\]

end while

Since $X$ is finite the above algorithm must terminate. By construction $\bar{S}$ is a circular split system and an unrooted family, and if $S' \supset S$, then we must also have $S' \supset \bar{S}$. By Proposition 9 there is a unique PC-tree $T$ with $\beta(T) = \bar{S}$. We have shown that if $T'$ is another PC-tree with $\beta(T') \supset S$, then $\beta(T') \supset \beta(T)$, so in a well-defined sense $T$ is the “best-fit” PC-tree for $D$. Let $\xi(D) = (S, w)$ be the weighted circular split system corresponding to $D$ and let $\bar{w}$ be a weighting on $\bar{S}$ given by extending $w$ as

$$\bar{w}(S) = \begin{cases} w(S) & S \in S, \\ 0 & S \in \bar{S} - S. \end{cases}$$

Then $\nu(\bar{S}, \bar{w}) = D$ and if $(S', w')$ is a weighted circular split system with $\xi((S', w')) = D$, then $S' \supset \bar{S}$ and $w' = w$ on $S$, $w' = 0$ on $S' - S$. □

We now explore how this construction looks on the affine side.

**Definition 16.** Let $D$ be a metric on $X$ and choose $r \in X$. The *Gromov product based at $r$* is defined by

$$2\phi_r(D)(x, y) = D(x, y) - D(x, r) - D(y, r) \quad \forall x, y \in X \setminus \{r\}. \quad (6)$$

The Gromov product is also known as the *Farris transform* [11, 15] in phylogenetics. It is easy to check that the map

$$\psi_r(R)(x, y) = 2R(x, y) - R(x, x) - R(y, y).$$
satisfies $\psi_r \circ \phi_r(D) = D$ and so is its inverse.

**Definition 17.** A matrix $R$ is Robinsonian over $X$ if there exists a linear ordering $\prec$ of $X$ such that

$$\max\{R(x,y), R(y,z)\} \leq R(x,z) \quad \forall x \preceq y \preceq z.$$ 

$R$ is a strong Robinsonian matrix if, in addition, for all $w \preceq x \preceq y \preceq z$,

$$R(x,y) = R(w,y) = \Rightarrow R(x,z) = R(w,z). \quad (7)$$

$$R(x,y) = R(x,z) = \Rightarrow R(w,z) = R(w,y). \quad (8)$$

In [7] it is shown that if $D$ is Kalmanson then $\phi_r(D)$ is a strong Robinsonian matrix. Here, we give a slightly more precise characterization of the image.

**Lemma 3.** Let $D$ be a Kalmanson dissimilarity map and $R = \phi_r(D)$. Then $R$ is a strong Robinsonian matrix with the following properties:

1. $R(x,y) \leq 0$ for all $x,y \in X$,
2. For every $w \preceq x \preceq y \preceq z$,

$$R(x,y) + R(w,z) \leq R(x,z) + R(w,y). \quad (9)$$

Furthermore, $\phi_r$ is a bijection from Kalmanson dissimilarities to the space of these matrices.

**Proof.** Suppose $D$ is Kalmanson with respect to the order $\{x_1, x_2, \ldots, x_n, r\}$ and $R = \phi_r(D)$. It is immediate from the definition of the Gromov product (6) and the Kalmanson condition (2) that $\phi_r(D)$ satisfies the above conditions with linear ordering $x_1 \prec x_2 \prec \ldots \prec x_n$. For $w \preceq x \preceq y \preceq z$,

$$2(R(x,z) - R(x,y)) = D(x,z) + D(y,r) - D(x,y) - D(z,r) \geq 0,$$

so $R(x,z) \geq R(x,y)$. Similarly $R(x,z) \geq R(y,z)$, so $R$ is Robinsonian. Now assume $R(x,y) = R(x,z)$. Then (9) gives $R(w,z) \leq R(w,y)$, and since $R$ is Robinsonian we also have the reverse inequality, so $R(w,z) = R(w,y)$. Similarly if $R(x,y) = R(w,y)$ then $R(x,z) = R(w,z)$, so $R$ is strong.

Conversely, let $R$ be a strong Robinsonian matrix satisfying (9). Then $\psi_r(R)$ clearly satisfies the Kalmanson conditions. Also,

$$\psi_r(x,y) = (R(x,y) - R(x,x)) + (R(x,y) - R(y,y)) \geq 0,$$

and $\psi_r(x,x) = 0$ for all $x,y \in X$. So $\psi_r(R)$ is a Kalmanson dissimilarity. The maps $\phi_r$ and $\psi_r$ are inverses, completing the proof. \qed

Therefore the image of $\phi_r$ consists of negative strong Robinsonian matrices satisfying a kind of four-point condition (9).

Next we define the affine analogue of weighted circular split systems.

**Definition 18.** Let $\mathcal{P}$ be a pyramid. A function $f : \mathcal{P} \to \mathbb{R}$ is an indexing function if $A \subset B \implies f(A) < f(B)$ for all $A, B \in \mathcal{P}$. We call $(\mathcal{P}, f)$ an indexed pyramid.
**Definition 19.** A subset $A \subseteq X$ is maximally linked $\square$ with respect to a Robinsonian matrix $R$ if there exists $d \in \mathbb{R}$ such that $R(x, y) \leq d$ for all $x, y \in A$, and $A$ is maximal in this way. If $A$ is such a set, define the diameter of $A$ to be $\text{diam}(A) = \max_{x,y \in A} R(x,y)$.

Let $\mathcal{M}(R)$ denote the set of maximally linked sets with respect to Robinsonian matrix $R$ and define the function $f : \mathcal{M}(R) \to \mathbb{R}$ by $f(A) = \text{diam}(A)$.

**Proposition 10.** The map $\tau : R \to (\mathcal{M}(R), f)$ is a bijection from Robinsonian matrices to indexed prepyramids, and from strong Robinsonian matrices to indexed pyramids.

**Proof.** Suppose $A \in \mathcal{M}(R)$ for $R$ Robinsonian and let $a, b \in A$ be the leftmost and rightmost points in $A$. Then for every $a \leq x < y \leq b$, $R(x, y) \leq R(a, b)$, so $\text{diam}(A) = M(a, b)$. This shows $x \in A$ for all $a \leq x \leq b$, so every set in $\mathcal{M}(R)$ is an interval. Now suppose $A, B \in \mathcal{M}(R)$ with $A \subseteq B$. Let $A = [x_1, y_1], B = [x_2, y_2]$. Then $x_2 \leq x_1 \leq y_1 \leq y_2$, and

$$f(A) = \text{diam}(A) = R(x_1, y_1) < R(x_2, y_2) = \text{diam}(B) = f(B),$$

where the inequality follows from the fact that $A$ is a maximally-linked set. So $f$ is an index and $\tau(R)$ is an indexed pyramid.

Conversely, consider the map $\mu$ from indexed prepyramids to matrices given by

$$\mu(\mathcal{P}, f)(x, y) = \min_{A \in \mathcal{P}} f(A).$$

Let $R = \mu(\mathcal{P}, f)$. Given $x \leq y \leq z$, let $E = \{A \in \mathcal{P}| x, y \in A\}$, $F = \{A \in \mathcal{P}| x, z \in A\}$. Then $F \subseteq E$, so

$$R(x, y) = \min_{A \in E} f(A) \leq \min_{A \in F} f(A) = R(x, z).$$

Similarly $R(y, z) \leq R(x, z)$, so $R$ is Robinsonian. It is easy to check that $\mathcal{P}$ consists precisely of the sets that are maximally linked with respect to $R$, so $\tau$ and $\mu$ are inverses.

Now suppose $R$ is a strong Robinsonian matrix. We must show $\tau(R)$ is closed under intersection. Let $A = [a_1, b_1], B = [a_2, b_2]$ be sets in $\mathcal{P}$, suppose $a_1 < a_2 \leq b_1 < b_2$ and let $C = A \cap B = [a_2, b_1]$. We will show $C$ is a maximally linked set with diameter $R(a_2, b_1)$. If $x \succ b_1$, the Robinsonian condition gives $R(a_2, x) \geq R(a_2, b_1)$. If there was equality then by the strong Robinsonian condition $R(a_1, x) = R(a_1, b_1)$ and $x \in A$, a contradiction. Similarly, there is no $x \prec a_2$ with $R(x, b_1) = R(y, a_1)$, so $C \in \mathcal{P}$ and $\mathcal{P}$ is closed under intersection.

Conversely, suppose $(\mathcal{P}, f)$ is an indexed pyramid and let $R = \mu((\mathcal{P}, f))$. Because $\mathcal{P}$ is closed under intersection, for each $A \subseteq X$ there is a unique $\bar{A} \in \mathcal{P}$ such that $A \subseteq \bar{A}$, and $\bar{A} \subseteq B$ for all $A \subseteq B \in \mathcal{P}$. This follows immediately from taking $\bar{A} = \bigcap_{A \subseteq B \in \mathcal{P}} B$. So now, suppose $w \prec x \prec y \prec z$ and $R(x, y) = R(x, z)$. The set $A := \{x, y\} \cap \{w, y\}$ is in $\mathcal{P}$ since $\mathcal{P}$ is closed under intersection. $f(\{x, y\}) = f(\{x, z\})$ which implies $z \in \{x, y\}$. Now $x, y \in A$ implies $\{x, y\} \in A$, so $z \in A$. But then $z \in \{w, y\}$ which
Proposition 12. If \( \tau \) is a kind of four-point property for pyramids, and we will refer to it as such reversible, so we see \( R \) because there does not exist \( C \in \mathcal{P} \) such that \( A \subset C \subset B \).

Lemma 4. Let \( \mathcal{P} \) be a pyramid. Then each set in \( \mathcal{P} \) has at most two predecessors.

Proof. Suppose there is an \( A = [a,b] \in \mathcal{P} \) with three distinct predecessors \( B_i = [a_i,b_i], i = 1,2,3 \). Because \( \mathcal{P} \) is closed under intersection \( B_i \cap B_j = A \) so either \( a_i = a \) or \( b_i = b \). By the pigeonhole principle two of the \( B_i \)'s must share an endpoint, so assume \( a_1 = a_2 = a \). Then either \( B_1 \subset B_2 \) or \( B_2 \subset B_1 \) contradicting the fact that each \( B_i \) is a predecessor of \( A \).

For a set \( A \in \mathcal{P} \), let \( P_A = \{ P_i \} \) denote the predecessors of \( A \). If \((\mathcal{P}, f)\) is an indexed pyramid, we define the map \( w : \mathcal{P} \to \mathbb{R} \) as the unique function satisfying

\[
w(A) = \begin{cases} -f(A) & \text{if } |P_A| = 0, \\ -f(A) + f(P_1) & \text{if } |P_A| = 1, \\ -f(A) + f(P_1) + f(P_2) - f(P_1 \cup P_2) & \text{if } |P_A| = 2. \end{cases}
\]

By Lemma 4 this is well-defined.

Proposition 11. Let \( R \) be a negative strong Robinsonian matrix satisfying the Robinsonian four-point condition, and take \( \tau(R) = (\mathcal{P}, f) \). Then \( f \) is negative, and \( w(A) \geq 0 \) for all \( A \in \mathcal{P} \). Furthermore, every such indexed pyramid lies in the image of \( \tau \).

Proof. Let \( R \) be a negative Robinsonian matrix satisfying (9). Clearly (10) holds for \( |P_A| = 0 \) because \( f \) is negative, and holds for \( |P_A| = 1 \) because \( P_1 \supset A \implies f(P_1) > f(A) \). So now assume \( A = [x,y] \) has two predecessors. By the argument in Lemma 4 these must be of the form \( B_1 = [w,y] \) and \( B_w = [x,z] \) for some \( w < x < y < z \), so

\[
w(A) = -f([x,y]) + f([w,y]) + f([w,z]) - f([w,z]) = -R(x,y) + R(w,y) + R(w,z) - R(w,z) \geq 0,
\]

because \( R \) satisfies the Robinsonian four-point condition. This argument is reversible, so we see \( \tau \) really is a bijection.

The requirement that \( w(A) \geq 0 \) for \( A \) with two predecessors (10) is thus a kind of four-point property for pyramids, and we will refer to it as such later.

Let \( \eta_r \) be the map sending \((\mathcal{P}, f)\) to the weighted circular split system \((\mathcal{S}, w')\) given by \( \mathcal{S} = \{ \delta_r(A) | A \in \mathcal{P} \}, w'(\delta_r(A)) = w(A) \).

Proposition 12. If \( D \) is a Kalmanson metric, then \( \nu \circ \eta_r \circ \tau \circ \phi_r \) is the identity map.
Proof. Let $D' = \nu \circ \eta_r \circ \tau \circ \phi_r(D)$ and for $A \in \mathcal{P}$, let $O_A = \{ B \in \mathcal{P} | A \subseteq B \}$ be the sets over $A$. A split $\delta_r(A)$ separates $x, y \in X \setminus \{r\}$ if $x \in A$ or $y \in A$ but not both. So the split pseudometric $D_{\delta_r(A)}(x, y)$ is 1 iff $A \in O_{\{x\}} \setminus O_{\{x, y\}}$ or $A \in O_{\{y\}} \setminus O_{\{x, y\}}$. Then

$$D'(x, y) = \sum_{A \in O_{\{x\}}} w(A) - \sum_{A \in O_{\{x, y\}}} w(A) + \sum_{A \in O_{\{y\}}} w(A) - \sum_{A \in O_{\{x, y\}}} w(A). \quad (11)$$

Now $O_A = O_{\bar{A}}$, so by an easy induction

$$\sum_{B \in O_A} w(B) = \sum_{B \in O_{\bar{A}}} w(B) = -f(\bar{A}),$$

and $D'(x, y) = 2f(\{x, y\}) - f(\{x\}) - f(\{y\})$. Since $f(\bar{A}) = \text{diam}(A)$, by the definition of the Gromov transform,

$$D'(x, y) = D(x, y) - D(x, r) - D(y, r) + D(x, r) + D(y, r) = D(x, y).$$

To compute $D'(x, r)$ we note $x$ and $r$ are separated by a split $\delta_r(A)$ iff $x \in A$, so

$$D'(x, r) = \sum_{A \in O_{\{x, r\}}} w(A) = -f(\{x\}) = -\phi_r(D)(x, x) = D(x, r).$$

Let $R$ be a Robinsonian matrix over $X$. If the prepyramid $\mathcal{P}$ in $\tau(R)$ is a rooted set family, Proposition 6 shows there exists a PQ-tree $T$ such that $\alpha(T) = \mathcal{P}$. Unfortunately this is usually not the case, so we seek instead to find a “best fit” tree. Analogous to the projective case, we construct the rooted closure $\mathcal{P}'$ of $\mathcal{P}$ with the following algorithm.

\begin{verbatim}
\text{\textbf{while} } \mathcal{P} \text{ contains a pair of incompatible sets } A, B \text{ \textbf{do}}
  \mathcal{P} \leftarrow \mathcal{H} \cup \{ A \cup B, A \cap B, A \setminus B, B \setminus A \}
\text{\textbf{end while}}
\end{verbatim}

Let $\theta$ be the closure map sending $\mathcal{P}$ to $\mathcal{P}'$. We then have the affine analog of Theorem 5.

**Lemma 5.** The PQ-tree $T$ with $\alpha(T) = \theta(\mathcal{P})$ is the unique tree with $\alpha(T) \supseteq \mathcal{P}$ that minimizes $|\alpha(T)|$.

It remains to show that $\theta$ commutes with the rest of the diagram. Let $D$ be a Kalmanson metric, $\mathcal{S}$ the corresponding split system and $\mathcal{P}$ the associated indexed pyramid. There is not necessarily a bijection between the intervals in $\mathcal{P}$ and the splits in $\mathcal{S}$; this can be seen, for example, because $\mathcal{P}$ is closed under intersection while $\mathcal{S}$ need not be. The splits in $\mathcal{P}$ that are not in $\mathcal{S}$ will get assigned weight zero by the map $\eta_r$, which is why the lower rectangle commutes, but the maps $\theta$ and $\iota$ forget about the weights so it’s not clear that $\theta \circ \delta_r = \iota \circ \psi_r$. Fortunately, for pyramids that arise from Kalmanson metrics this bijection holds.

**Lemma 6.** $\delta_r \circ \theta \circ \tau \circ \phi_r(D) = \iota \circ \xi(D)$ for all Kalmanson metrics $D$. 

Proof. Let \((P, f) = \tau \circ \phi_r(D)\) and let \((S, w)\) the corresponding weighted split system. Suppose \(A \in P\) but \(\delta_r(A) \notin S\), or equivalently \(f(A) = 0\).

\(A = [a, b]\) is an interval with respect to the Robinsonian metric. If \(c \succ b\) then \(M(a, c) > M(a, b)\) because \(c / \in A\), so

\[0 < M(a, c) - M(a, b) = f(a, c) - f(a, b) = - \sum_{\substack{B \in P \cr a, c \in B}} w(B) + \sum_{\substack{B \in P \cr a, b \in B}} w(B).\]

The first summand is a subset of the second, so there exists \(B \in P\) with \(a, b \in B\), \(c \notin B\) and \(w(B) > 0\). Letting \(c\) be the smallest element with \(c \succ b\) shows there exists a set \(C = [a, y] \in P\) with \(w(C) > 0\) and \(y \succ b\). Similarly there exists a set \(C = [a, y] \in P\) with \(w(C) > 0\) and \(y \succ b\). So \(A = B \cap C\) for sets \(B, C \in P\) that correspond to splits of positive weight in \(S\), and thus \(\delta_r(A) \in \iota \circ \eta(S)\). This completes the proof. \(\square\)

We are now ready to state our final result that summarizes the bijections described above. Let \(PC\) be the set of all PC-trees, \(CUF\) the set of all circular, unrooted split families, \(WCSS\) the set of all weighted circular split systems, and \(K\) the set of all Kalmanson metrics, all over \(X\). Let \(PQ\) be the set of all \(PQ\)-trees, \(PRF\) the set of pyramidal rooted families, \(IP\) the set of negative indexed pyramids satisfying the pyramidal four-point condition, and \(SR\) the set of negative strong Robinsonian matrices satisfying the Robinsonian four-point condition, all over \(X \setminus \{r\}\).

**Theorem 4.** The following diagram commutes:

\[
\begin{array}{ccc}
PQ & \xleftarrow{\kappa_r} & PC \\
\downarrow{\alpha} & & \downarrow{\lambda_r} \\
PRF & \xleftarrow{\delta_r} & CUF \\
\downarrow{\theta} & & \downarrow{\iota} \\
IP & \xleftrightarrow{\tau} & WCSS \\
\downarrow{\mu} & & \downarrow{\xi} \\
SR & \xleftarrow{\psi_r} & K \\
\end{array}
\]

This gives a way of constructing the best-fit PC-tree for a given Kalmanson metric \(D\):

\[T = \kappa_r \circ \alpha^{-1} \circ \theta \circ \tau \circ \phi_r(D).\]

An example illustrating Theorem 4 is shown in Figure 6. The PC-tree in the upper right reveals the tree structure in the Kalmanson metric (see also Figure 2).

As a final remark, we note that the geometry of Kalmanson metrics is also explored in [28], where the Kalmanson complex is described. PC-trees are faces in this complex, and it should be interesting to understand their combinatorics in the face lattice.
