Simultaneous Observation of Visible Upconversion and Near-Infrared Downconversion in SrF$_2$:Nd$^{3+}$/Yb$^{3+}$/Er$^{3+}$ Nanocrystals and Their Application for Detecting Metal Ions under Dual-Wavelength Excitation

Linxuan Wang,¶ Weiqiang Yang,¶ Liang Li, Shuai Hu, Maohui Yuan,*, Zining Yang, Kai Han, Hongyan Wang,*, and Xiaojun Xu

ABSTRACT: In this work, a sequence of Nd$^{3+}$, Yb$^{3+}$, and Er$^{3+}$ tridoped SrF$_2$ nanocrystals (NCs) is synthesized by a hydrothermal method. Both the efficient near-infrared downconversion luminescence (DCL) and visible upconversion luminescence (UCL) of the Er$^{3+}$ and Nd$^{3+}$ ions are simultaneously observed and systematically demonstrated under dual-wavelength excitation (808 and 980 nm continuous-wave lasers). Subsequently, the SrF$_2$:Nd$^{3+}$/Yb$^{3+}$/Er$^{3+}$ (15/4/0.2 mol %) NCs with the strongest luminescence were utilized for detecting the metal ion concentrations under 808 nm excitation. The results reveal that both the UCL and DCL gradually decrease as the metal ion concentrations increase, and high sensitivity is obtained for Cu$^{2+}$ ions with a detection limit of 0.22 nM (∼650 nm) and 0.63 nM (∼976 nm). In addition, these SrF$_2$:Nd$^{3+}$/Yb$^{3+}$/Er$^{3+}$ NCs are further demonstrated to achieve a solid-state display under 980 nm excitation, exhibiting obvious “red” and “green” patterns by varying the doping rare earth ion concentrations.

1. INTRODUCTION

In recent years, lanthanide-based upconversion nanocrystals (NCs) have become a research hotspot due to their significant advantages of a long fluorescence lifetime, narrow spectral width, large anti-Stokes shift, and low biotoxicity, which have been widely applied in temperature sensing,¹−³ biological therapy,⁴ micro-/nanolasers,⁵,⁶ solar cells,⁷ and other aspects.⁸⁻¹⁰ Generally, the so-called upconversion luminescence (UCL) process is an important approach for obtaining efficient luminescence emission. UCL refers to the conversion of lower-energy near-infrared (NIR) photons into relatively high-energy visible light through continuous photon absorption and energy-transfer (ET) processes based on the activator—sensitizer pairs.²⁻⁶ Popularity, Er$^{3+}$ ions are used as activators emitting UCL, while the Yb$^{3+}$ and Nd$^{3+}$ ions act as sensitizers absorbing the excitation energy. Meanwhile, Er$^{3+}$ and Nd$^{3+}$ ions have abundant energy levels, whose main emission peaks range from visible to NIR regions. Compared to Yb$^{3+}$ ions, Nd$^{3+}$ ions have a larger absorption cross-section (1.2 × 10⁻¹⁹ cm²) at 808 nm, which is about 10 times greater than that of Yb$^{3+}$ ions at 980 nm.¹⁰ In contrast, the water absorption coefficient of Nd$^{3+}$ at 808 nm (0.02 cm⁻¹) is much lower than that of Yb$^{3+}$ ions at 980 nm (0.48 cm⁻¹).¹¹ Thus, the Nd$^{3+}$-sensitized NCs have been widely utilized in biological issues or aqueous environment applications.

The host material has the most important role in generating both UCL and downconversion luminescence (DCL). In general, the low phonon energy of the host lattice is likely to reduce the nonradiative (NR) transition rates, thus promoting emission efficiency. Fluorides have a relatively low phonon energy (∼350 cm⁻¹), as well as strong ionic properties, high transmittance in a wide spectral range from ultraviolet to infrared, high damage threshold, a low refractive index, easy storage, and other superior properties,¹²,¹³ which have been utilized for doping rare earth ions and applied in many practical fields. Among these fluorides, SrF$_2$ is a promising host matrix with a cubic fluor spar structure and has attracted great attention.¹⁴,¹⁵ Until now, many researchers have focused on investigating the UCL properties of NCs doped with either

Yb	extsuperscript{3+} or Nd	extsuperscript{3+} ions as sensitizers. However, there are still few reports on the simultaneous realization of UCL and DCL generation in lanthanide-doped NCs, especially for tridoping with Nd	extsuperscript{3+}, Yb	extsuperscript{3+}, and Er	extsuperscript{3+} ions. This can achieve 980 and 808 nm dual-wavelength excitation and further promote their applications in both aqueous and nonaqueous environments.

With the development of society and industry, human beings have higher requirements for water quality. How to quickly and accurately detect the amount of metal ions in a water environment is particularly important. The Cu	extsuperscript{2+} ion is an essential trace element in the human body, and it is needed to catalyze many biochemical processes in the body, but too much intake will lead to cancer and other diseases. The maximum allowance of Cu	extsuperscript{2+} ions in drinking water, given by the World Health Organization (WHO), is ~31.5 μM. At present, although the quantitative methods of metal ion detection include atomic absorption spectrometry, inductively coupled plasma mass spectrometry, or emission spectrometry, these methods are complicated and costly. In contrast, the optical sensors based on lanthanide-doped NCs are popularly employed to detect metal ions in the environment owing to their low cost and high sensitivity with fast response times. Numerous reports have shown that lanthanide-doped NCs have good selectivity and high sensitivity for the detection of various metal ions. Nevertheless, the present majority of sensors are operated by either singly detecting the UCL signal or under 980 nm excitation. In this work, we have synthesized the Nd	extsuperscript{3+}, Yb	extsuperscript{3+}, and Er	extsuperscript{3+} tridoped SrF	extsubscript{2} NCs through a hydrothermal approach. The structure of these SrF	extsubscript{2} NCs was systematically characterized. Subsequently, we simultaneously investigated the visible UCL and NIR DCL properties in these NCs under the dual-wavelength excitation (both 808 and 980 nm). The dynamic properties, mechanism of population, and ET and emission processes are also demonstrated. Furthermore, the SrF	extsubscript{2}:Nd	extsuperscript{3+}/Yb	extsuperscript{3+}/Er	extsuperscript{3+} (15/4/0.2 mol %) NCs were selected to act as high-sensitivity optical sensors for the detection of Cu	extsuperscript{2+} ions and other kinds of metal ions under 808 nm excitation. In addition, a potential solid-state display with different patterns is also demonstrated.

2. EXPERIMENTAL SECTION

2.1. Synthesis of Nanocrystals. The raw chemicals of SrCl	extsubscript{2}, 6H	extsubscript{2}O (99.99%), YbCl	extsubscript{3}, 6H	extsubscript{2}O (99.9%), NdCl	extsubscript{3}, 6H	extsubscript{2}O (99.9%), ErCl	extsubscript{3}, 6H	extsubscript{2}O (99.9%), Na	extsubscript{2}C	extsubscript{6}H	extsubscript{5}O	extsubscript{7}·3H	extsubscript{2}O (98%), and NH	extsubscript{4}F (98%) were all purchased from Aladdin (China). The procedure of the synthesis of NCs is similar to that in our previous report. Taking SrF	extsubscript{2}:Nd	extsuperscript{3+}/Yb	extsuperscript{3+}/Er	extsuperscript{3+} (15/4/1 mol %) NCs as an example, 10 mL of solution of chloride salts (1.6 mmol SrCl	extsubscript{2}·3 mmol NdCl	extsubscript{3}, 0.3 mmol YbCl	extsubscript{3}, 0.08 mmol ErCl	extsubscript{3}, and 0.02 mmol Na	extsubscript{2}C	extsubscript{6}H	extsubscript{5}O	extsubscript{7}) and 10 mL of aqueous solution of sodium citrate (1 M) were mixed under stirring for 1 h. Sequentially, 20 mL of aqueous solution of NH	extsubscript{4}F (1 M) was added into the above mixed solutions. The mixtures were stirred for 30 min and then transferred into a 50 mL Teflon-lined autoclave and heated at 200 °C for 8 h. After the reaction, the autoclave was naturally cooled down to room temperature. The as-prepared SrF	extsubscript{2} NCs were collected by centrifugation at 6000 rpm for 4 min, washed and then dried at 60 °C for 12 h.

2.2. Characterization. The morphology and size of the as-prepared SrF	extsubscript{2} NCs were characterized by transmission electron microscopy (TEM). X-ray diffraction (XRD) patterns were measured using a powder diffractometer (Bruker D8 Advance) working in a Bragg–Brentano geometry ray with a copper anode X-ray source and a cooled solid-state detector. The visible and NIR luminescence spectra of SrF	extsubscript{2}:Nd	extsuperscript{3+}/Yb	extsuperscript{3+}/Er	extsuperscript{3+} NCs were measured using a fluorescence spectrophotometer (Zolix Omni-13072i) coupled with an R928 photomultiplier tube or an InGaAs avalanche photodetector under the excitation of 808 and 980 nm lasers.

2.3. Metal Ion Detection Studies Using SrF	extsubscript{2}:Nd	extsuperscript{3+}/Yb	extsuperscript{3+}/Er	extsuperscript{3+} NCs. Taking the preparation of the Cu	extsuperscript{2+} ion solution (10⁻⁸ M) as an example, first, 0.5 mL of the other solutions were added into 20 mL aqueous solution of NaCl (1 M) and then stirred for 1 h. Following this, 10 mL of aqueous solution of citrate (1 M) was added into the above solution and then transferred into a 50 mL Teflon-lined autoclave and heated at 120 °C for 12 h. After the reaction, the autoclave was naturally cooled down to room temperature. The as-prepared SrF	extsubscript{2} NCs were collected by centrifugation at 6000 rpm for 4 min, washed and then dried at 60 °C for 12 h.
3. RESULTS AND DISCUSSION

3.1. Structure. Figure 1a–e shows the TEM images of SrF₂:Nd³⁺/Yb³⁺ (15/4 mol %) NCs doped with different concentrations of Er³⁺ ions. It reveals that the prepared NCs are evenly distributed and mainly elliptic or square. Through the statistical analysis, the average size of the particle is approximately ∼55 nm, as shown in Figure 1f. The NCs are relatively uniform in size with small deviations. The results indicate that the doping of different concentrations of rare earth ions has little influence on the morphology and size of the SrF₂ NCs.

Figure 2 shows the XRD patterns of the SrF₂:Nd³⁺/Yb³⁺ (15/4 mol %) NCs doped with different Er³⁺ ion concentrations. All the measured diffraction peaks of the samples can be well matched to the standard diffraction data of SrF₂ (JCPDS card no. 06-0262), meaning that these as-prepared SrF₂ NCs all crystallize in a cubic structure with a space group of Fm3m (225). Nevertheless, as the doping concentrations of Nd³⁺, Yb³⁺, and Er³⁺ ions increase, the XRD peak (2θ = 26.77°) shifts slightly to a larger degree compared to that of the pure SrF₂. The reason is that the radii of Yb³⁺ (0.86 Å), Nd³⁺ (0.99 Å), and Er³⁺ (0.88 Å) are all smaller than those of the Sr²⁺ ions (1.18 Å). When the bivalent Sr²⁺ ions are replaced by trivalent Yb³⁺ (Nd³⁺ or Er³⁺) ions, the distance between the lattice planes becomes smaller, thus leading to the diffraction angle increasing according to the Bragg equation. No impurity phase is detected, indicating that the Nd³⁺, Yb³⁺, and Er³⁺ tridoped SrF₂ NCs have been successfully synthesized.

3.2. Photoluminescence. Figure 3 shows both UCL and DCL spectra of Nd³⁺/Yb³⁺/Er³⁺ tridoped SrF₂ NCs under the dual-wavelength excitation of 808 and 980 nm lasers. Efficient UCL and DCL can be detected. The pumping power intensity is 0.1 W cm⁻² in our experiments to avoid or minimize the effects of laser-induced heat. Although the UCL and DCL can be efficiently observed at both 808 and 980 nm excitations at the same time, the total emission intensity obtained by an excitation of 808 nm is almost 10 times that by the 980 nm excitation under the same measurement conditions. This is because of the relatively larger absorption cross-section of Nd³⁺ at 808 nm compared to that of Yb³⁺ ions at 980 nm, as previously explained in the Introduction section.

As shown in Figure 3a, under the excitation of an 808 nm laser, typical UCL emissions of Er³⁺ can be clearly observed. The UCL emissions centered at 410, 521, 540, and 650 nm are ascribed to the ⁴F₇/₂ → ⁴I₁₅/₂, ⁴F₇/₂ → ⁴I₁₅/₂, ⁴S₅/₂ → ⁴I₁₅/₂, and ⁴F₇/₂ → ⁴I₁₅/₂ transitions from Er³⁺ ions, respectively. In the NIR DCL spectra shown in Figure 3b, the peaks at 980 nm originate from the ⁴F₅/₂ → ⁴H₁₃/₂ transitions from Yb³⁺ ions, while the peaks at 867, 1056, and 1330 nm originate from the ⁴F₅/₂ → ⁴I₉/₂, ⁴F₅/₂ → ⁴I₁₁/₂, and ⁴F₅/₂ → ⁴I₁₁/₂ transitions from Nd³⁺ ions, respectively. The spectral intensity of the NCs gradually decreases with the increase of Er³⁺ concentration, and 2% Er³⁺ is the optimal concentration for achieving the strongest luminescence output. Under the excitation of a 980 nm laser, the shape of the spectra and the concentration-dependent luminescence are the same as those of the NCs excited under 808 nm, as shown in Figure 3c.d.

To clarify the ET mechanism of SrF₂:Nd³⁺/Yb³⁺/Er³⁺ NCs excited at 808 and 980 nm, Figure 4 displays the energy level diagram containing the ET processes, excited-state absorption (ESA), cross-relaxation (CR), and NR transition. Under the excitation of 808 nm, when the NCs are doped with Nd³⁺ and Yb³⁺ ions, Nd³⁺ ions can be populated through the ⁴I₉/₂ → ⁴F₄/₂ transition by absorbing 808 nm photons. Subsequently, the electrons in the ⁴F₅/₂ state will transition to the ⁴I₉/₂, ⁴I₁₁/₂, and ⁴I₁₃/₂ states, thereby emitting the NIR light at 867, 1056, and 1330 nm, respectively. Sectional electrons in the ⁴F₅/₂ state reach the ⁴G₇/₂ state by the ESA process and then populate the excited states of ⁴G₇/₂, ⁴G₉/₂, and ⁴G₉/₂ by NR transitions, generating the UCL signals at 542, 586, and 667 nm, respectively. In addition, the ⁴F₅/₂ state of Nd³⁺ can populate the ⁴F₅/₂ state of Yb³⁺ through the ET process, thus producing 976 nm NIR DCL. When further introduced with Er³⁺ ions, the Nd³⁺ ions could populate the ⁴F₅/₂ state of adjacent Yb³⁺ by ET processes and sequentially transfer energy to the ⁴I₁₁/₂, ⁴F₅/₂, and ⁴H₉/₂ states of Er³⁺ ions through several successive ET processes. In addition, besides the population process of Nd³⁺ → Yb³⁺ → Er³⁺ mentioned above, Nd³⁺ can directly populate the ⁴I₉/₂ and ⁴H₉/₂ states of Er³⁺ ions through the ET process (Nd³⁺ → Er³⁺) between Nd³⁺ and Yb³⁺ ions. The efficient population of the high-energy states of Er³⁺ can relax them to the corresponding excited states through the NR transition, such as ⁴H₉/₂ → ⁴I₁₅/₂, ⁴S₅/₂, and ⁴F₇/₂ states, thus generating the UCL centered at 410, 521, 540, and 650 nm, respectively.

Instead of Nd³⁺ ions absorbing 808 nm photons, the Yb³⁺ ions can absorb 980 nm photons directly to make the transition of ⁴F₇/₂ → ⁴F₅/₂. On the one hand, Yb³⁺ as the sensitizer will transfer energy to the adjacent Nd³⁺ ions through ET processes, populating the ⁴G₉/₂ and ⁴F₅/₂ states of

Figure 2. XRD patterns of SrF₂:Nd³⁺/Yb³⁺/Er³⁺ (15/4/x mol %) NCs doped with different Er³⁺ ion concentrations.
Nd\(^{3+}\) ions. Especially, the CR1 process can significantly populate the \(4F_{5/2}\) state. This can efficiently generate the 804 nm UCL compared to pumped at 808 nm laser. In addition, the CR2 process of \(4I_{9/2}\) (Nd\(^{3+}\)) \(\rightarrow \) \(4F_{9/2}\) (Er\(^{3+}\)) → \(4I_{15/2}\) (Er\(^{3+}\)) \(\rightarrow \) \(4F_{9/2}\) (Nd\(^{3+}\)) will promote the population of the \(4F_{9/2}\) state of Nd\(^{3+}\) and then radiate to the \(4H_{7/2}\) state, achieving the 750 nm \((4H_{7/2} \rightarrow 4I_{9/2})\) emission.

On the other hand, Yb\(^{3+}\) can also transfer energy to Er\(^{3+}\) ions by ET processes to populate the \(4I_{11/2}\), \(4F_{9/2}\), \(4F_{7/2}\), and \(3H_{9/2}\) states of Er\(^{3+}\), thus leading to the typical UCL of Er\(^{3+}\).

Figure 3. Visible UCL and NIR DCL spectra of SrF\(_2\):Nd\(^{3+}\)/Yb\(^{3+}\)/Er\(^{3+}\) (15/4/x mol %) NCs doped with different Er\(^{3+}\) concentrations under the excitation of (a,b) 808 and (c,d) 980 nm, respectively.

Figure 4. Energy level diagram for SrF\(_2\):Nd\(^{3+}\)/Yb\(^{3+}\)/Er\(^{3+}\) NCs excited at 808 and 980 nm, respectively. The corresponding processes of ET, ESA, and CR; NR transitions; UCL and DCL channels are also provided.

3.3. Metal Ion Concentration Detection. Having demonstrated the efficient UCL and DCL of the as-prepared NCs, here, we select the SrF\(_2\):Nd\(^{3+}\)/Yb\(^{3+}\)/Er\(^{3+}\) (15/4/0.2 mol %) NCs as an optical sensor to detect the metal ion. Figure 6a gives the spectra of SrF\(_2\):Nd\(^{3+}\)/Yb\(^{3+}\)/Er\(^{3+}\) (15/4/0.2 mol %) NCs dispersed in different concentrations of Cu\(^{2+}\) ion solutions under the excitation of an 808 nm laser. With the increase of Cu\(^{2+}\) ion concentrations from 1 to 10 nM, the peak positions of the UCL and DCL remain unchanged. However, both the UCL and DCL gradually decrease when increasing the Cu\(^{2+}\) concentrations. The luminescence inhibition effect of the NCs becomes more obvious at relatively high Cu\(^{2+}\) concentrations. This is possibly caused by the addition of Cu\(^{2+}\) ions which inhibit the process of ET between the rare earth ions doped in the NCs. This luminescence quenching effect can be utilized for optical sensor detection of the metal ion concentrations. Generally, the Stern–Volmer equation is used to describe the photoluminescence quenching process (dynamic/static), which is defined as follows:

\[
I_0 / I = 1 + K_{SV} \times [Q]
\]

where \(I_0\) and \(I\) represent the luminescence intensity in the absence and presence of Cu\(^{2+}\) ions, respectively, \(K_{SV}\) is the dynamic quenching constant (Stern–Volmer quenching constant), and \(Q\) is the Cu\(^{2+}\) concentration of the solution. Based on the spectral data in Figure 6a, we have calculated the
ratios of 652 nm visible emission and 976 nm NIR light. Figure 6b,c shows the corresponding Stern–Volmer plots as a function of the Cu$^{2+}$ concentration. According to the plot, a linear relationship can be obtained between the luminescence ratio and the Cu$^{2+}$ ion concentration for both 652 nm ($R^2 = 0.984$) and 976 nm ($R^2 = 0.997$). The limit of detection.

Figure 5. Spectra of SrF$_2$:Nd$^{3+}$/Yb$^{3+}$/Er$^{3+}$ (15/4/0.2 mol %) NCs excited by (a) 808 and (c) 980 nm lasers with different pumping power densities. Double-logarithmic plots of luminescent intensity vs different pumping power densities under (b) 808 and (d) 980 nm.

Figure 6. (a) DCL and UCL intensity of SrF$_2$:Nd$^{3+}$/Yb$^{3+}$/Er$^{3+}$ (15/4/0.2 mol %) NCs as a function of the Cu$^{2+}$ ion concentrations. The Stern–Volmer plot as a function of Cu$^{2+}$ concentration for SrF$_2$:Nd$^{3+}$/Yb$^{3+}$/Er$^{3+}$ (15/4/0.2 mol %) NCs measured at (b) visible UCL (652 nm) and (c) NIR DCL (976 nm), respectively. The excitation wavelength is 808 nm.
(LOD) can be further calculated using the following formula:

\[
\text{LOD} = 3\sigma / S
\]

where \(\sigma\) is the standard deviation of the blank experiment and \(S\) is the slope of the calibration plot. In our measurements, \(\sigma\) is about \(3.77 \times 10^{-4}\), which is calculated after several measurements of the original sample without \(\text{Cu}^{2+}\) ion doping. According to the obtained parameters, the detection limit value was therefore calculated to be 0.22 nM (652 nm) and 0.63 nM (976 nm), respectively. This probed value is extremely higher than the maximum \(\text{Cu}^{2+}\) ion concentration (\(\sim 31.5 \mu\text{M}\)) permitted in drinking water given by the WHO. According to the obtained parameters, the detection limit value was therefore calculated to be 0.22 nM (652 nm) and 0.63 nM (976 nm), respectively. This probed value is extremely higher than the maximum \(\text{Cu}^{2+}\) ion concentration (\(\sim 31.5 \mu\text{M}\)) permitted in drinking water given by the WHO.

These NCs have a better detection accuracy for \(\text{Cu}^{2+}\) ion concentration detection, which is summarized in Table 1. Figure 7a,b displays the decay curve of the emission peak at 652 and 976 nm with changing the \(\text{Cu}^{2+}\) concentrations from 1 to 10 nM in the \(\text{SrF}_2:\text{Nd}^{3+}/\text{Yb}^{3+}/\text{Er}^{3+}\) NC sample under 808 nm excitation. Meanwhile, to clearly compare the lifetime variations, Figure 7c,d further shows the dependence of both the visible UCL and NIR DCL lifetimes on the \(\text{Cu}^{2+}\) concentrations. A single exponential function has been used to fit the lifetime of the fluorescence decay curves. It can be seen that both the lifetimes of 652 and 976 nm gradually decrease with the increase of \(\text{Cu}^{2+}\) concentrations. The lifetime of the transition \(4\text{F}_{9/2} \rightarrow 4\text{I}_{15/2}\) (652 nm) of \(\text{Er}^{3+}\) ions drops from 275.15 to 220.89 \(\mu\text{s}\) as well as that of the transition \(2\text{F}_{5/2} \rightarrow 2\text{F}_{7/2}\) (976 nm) of \(\text{Yb}^{3+}\) ions decreases from 338.43 to 306.72 \(\mu\text{s}\).

The excitation wavelengths are all 808 nm.

Table 1. LOD and Linearity Range Comparison of Various Samples Applied for the Detection of \(\text{Cu}^{2+}\) Ions
After investigating the detection of Cu^{2+} ion concentrations, we tried to detect other metal ions. Figure 8a shows the emission spectra of SrF\textsubscript{2}:Nd\textsuperscript{3+}/Yb\textsuperscript{3+}/Er\textsuperscript{3+} (15/4/0.2 mol %) NCs dispersed in different metal ions with the same concentration (10 nM) excited under an 808 nm laser. (b) Normalized spectral intensity of different kinds of metal ions (the luminescence intensity for the NCs without any metal ion is normalized as the reference value “1”).

Figure 8. (a) Spectra of SrF\textsubscript{2}:Nd\textsuperscript{3+}/Yb\textsuperscript{3+}/Er\textsuperscript{3+} (15/4/0.2 mol %) NCs dispersed in different metal ions with the same concentration (10 nM) excited under an 808 nm laser. (b) Normalized spectral intensity of different kinds of metal ions (the luminescence intensity for the NCs without any metal ion is normalized as the reference value “1”).

Figure 9. (a) Original pictures of a basketball (I), guitar (II), sailboat (III), umbrella (IV), and flower (V). (b) Displayed “red” and “green” patterns drawn with the prepared SrF\textsubscript{2} NCs doped with different Nd\textsuperscript{3+}, Yb\textsuperscript{3+}, and Er\textsuperscript{3+} ions under 980 nm laser illumination. The drawn NCs are (I) SrF\textsubscript{2}:Nd\textsuperscript{3+}/Yb\textsuperscript{3+}/Er\textsuperscript{3+} (15/4/0.5 mol %), (II) SrF\textsubscript{2}:Nd\textsuperscript{3+}/Yb\textsuperscript{3+}/Er\textsuperscript{3+} (15/4/1 mol %), (III) SrF\textsubscript{2}:Nd\textsuperscript{3+}/Yb\textsuperscript{3+}/Er\textsuperscript{3+} (15/4/2 mol %), (IV) SrF\textsubscript{2}:Nd\textsuperscript{3+}/Yb\textsuperscript{3+}/Er\textsuperscript{3+} (15/4/10 mol %), and (V) SrF\textsubscript{2}:Nd\textsuperscript{3+}/Yb\textsuperscript{3+}/Er\textsuperscript{3+} (10/2/1 mol %).

Figure 9. Picture I (basketball) is drawn with SrF\textsubscript{2}:Nd\textsuperscript{3+}/Yb\textsuperscript{3+}/Er\textsuperscript{3+} (15/4/0.5 mol %) NCs. It is noted that the excitation of different samples under the same wavelength laser can get different imaging colors. Bright and clear “red” patterns can be observed in pictures I (basketball), II (guitar), and III (sailboat) achieved with the SrF\textsubscript{2}:Nd\textsuperscript{3+}/Yb\textsuperscript{3+}/Er\textsuperscript{3+} (15/4/0.5 mol %), SrF\textsubscript{2}:Nd\textsuperscript{3+}/Yb\textsuperscript{3+}/Er\textsuperscript{3+} (15/4/1 mol %), and SrF\textsubscript{2}:Nd\textsuperscript{3+}/Yb\textsuperscript{3+}/Er\textsuperscript{3+} (15/4/2 mol %) NCs, respectively. Moreover, “green” patterns can be detected in pictures IV (umbrella) and V (flowers) when sealed with SrF\textsubscript{2}:Nd\textsuperscript{3+}/Yb\textsuperscript{3+}/Er\textsuperscript{3+} (15/4/10 mol %) and SrF\textsubscript{2}:Nd\textsuperscript{3+}/Yb\textsuperscript{3+}/Er\textsuperscript{3+} (10/2/1 mol %) NCs. Therefore, we fully believe that a specific color light output can be achieved through doping with different Nd\textsuperscript{3+}, Yb\textsuperscript{3+}, and Er\textsuperscript{3+} concentrations, which will greatly promote the development of solid-state display research.

4. CONCLUSIONS

In summary, we have fabricated the Nd\textsuperscript{3+}, Yb\textsuperscript{3+}, and Er\textsuperscript{3+} tridoped SrF\textsubscript{2} NCs with an average size of 55 nm by a hydrothermal method. Subsequently, their NIR DCL and visible UCL properties are systematically characterized under dual-wavelength excitation (both 808 and 980 nm lasers). The results verify that these NCs can simultaneously efficiently...
exhibit both the NIR DCL and UCL signals. Based on the spectra under dual-wavelength excitation, the mechanism of the DCL and UCL and populations of these SrF$_2$:Nd$^{3+}$/Yb$^{3+}$/Er$^{3+}$ NCs are demonstrated. Furthermore, the SrF$_2$:Nd$^{3+}$/Yb$^{3+}$/Er$^{3+}$ (15/4/0.2 mol %) NCs are further utilized for detecting the Cu$^{2+}$ ions, and the probe accuracy is on the nanomolar concentration scale (0.22 nM at 652 and 0.63 nM at 976 nm). It also reveals that these NCs can be applied for detection of other common metal ion concentration. In addition, we embedded the NCs doped with different Nd$^{3+}$, Yb$^{3+}$, and Er$^{3+}$ ions into the engraving structure pictures and achieved obvious “red” and “green” patterns for a solid-state imaging display. We firmly believe that these NCs have great potential applications in the detection of metal ion concentration and solid-state displays.
