Abstract

We consider the quantum angular momentum generators, deformed by means of the Dunkl operators. Together with the reflection operators they generate a subalgebra in the rational Cherednik algebra associated with a finite real reflection group. We find all the defining relations of the algebra, which appear to be quadratic, and we show that the algebra is of Poincaré-Birkhoff-Witt (PBW) type. We show that this algebra contains the angular part of the Calogero–Moser Hamiltonian and that together with constants it generates the centre of the algebra. We also consider the $gl(N)$ version of the subalgebra of the rational Cherednik algebra and show that it is a non-homogeneous quadratic algebra of PBW type as well. In this case the central generator can be identified with the usual Calogero–Moser Hamiltonian associated with the Coxeter group in the harmonic confinement.

I. INTRODUCTION

The differential-difference operators

$$D_i = \partial_{x_i} + \sum_{\alpha \in \mathcal{R}_+} \frac{g_\alpha \alpha_i}{(\alpha, x)} (1 - s_\alpha)$$

(1.1)

were introduced by Dunkl in [1] in the context of study of so called Dunkl-harmonic and multivariable orthogonal polynomials. Here $\mathcal{R}_+$ is a positive half of a Coxeter root system $\mathcal{R}$, and $s_\alpha$ are the corresponding orthogonal reflections from the associated Coxeter group $W$, $\alpha = (\alpha_1, \ldots, \alpha_N)$. In the case of $\mathcal{R} = A_{N-1}$ they take the form of the permutation operators $s_{ij}$ which act on the space of functions as follows:

$$(s_{ij}\psi)(x_1, \ldots, x_i, \ldots, x_j, \ldots x_N) = \psi(x_1, \ldots, x_j, \ldots, x_i, \ldots x_N).$$

The function $g(\alpha) = g_\alpha$ is $W$-invariant so in the case of type $A_{N-1}$ it is an arbitrary complex constant. The operators $D_i$ may be considered as $g$-dependent deformations of the partial differentiation operators $\partial_i = \partial_{x_i}$.

These operators play a key role in the theory of celebrated Calogero–Moser model [2] (see also the reviews [3], [4]). In particular, a complete set of quantum integrals can be described in terms of Dunkl operators [5]. Modifications of the operators (1.1) were used in [6, 7] to define creation-annihilation operators and quantum integrals for the rational Calogero-Moser model in the harmonic confinement.

The operators $D_i$ together with the multiplication operators $x_i$ and the group algebra $\mathbb{C}W$ with their standard action generate rational Cherednik algebra $H_g(W)$ [8]. We also refer to the books [9, 10] for the rich theory of Cherednik algebras and their connections to other areas.

In this paper we are concerned with the deformation of the quantum angular momentum generators, constructed by means of the Dunkl operators:

$$M_{ij} = x_i D_j - x_j D_i.$$  

(1.2)

Our motivation still comes from Calogero–Moser systems, and, more specifically, angular part of the rational quantum Calogero–Moser Hamiltonian. This system plays a role in the original Calogero’s work [2], and it has been studied more recently in a number of papers both in the classical [11, 12] and quantum [13, 14] cases. Thus the angular Hamiltonian
is shown to define a superintegrable system on $N - 1$ dimensional hypersphere ([12], see also [15]), and a way to represent conserved charges was developed in [11]. We note that identifying Liouville charges is still an open problem. The operators (1.2) were already used in [13] as building blocks for the intertwining operators between the angular Hamiltonians with coupling constants different by an integer.

In this paper we firstly deal with the subalgebra of the rational Cherednik algebra of type $A_{N-1}$ generated by the elements $M_{ij}$ and by the permutations $s_{ij}$. A close algebra already appeared in the work of V. Kuznetsov [16] in connection with the Calogero–Moser system. We explain that the angular Calogero–Moser Hamiltonian can be realised as an element in this algebra. Furthermore, we show that it generates the centre of the algebra. This operator can be considered as a deformation of the usual quadratic Casimir invariant of $so(N)$, which corresponds to the angular momentum square.

We also describe all the relations which generators $M_{ij}$ satisfy. The commutation relations are simple extensions of the usual $so(N)$ relations with metrics replaced by pairwise particle permutations. There are additional “crossing” relations which are quadratic in the generators too. We describe a basis in this algebra and show that it is a non-homogeneous quadratic algebra of Poincaré-Birkhoff-Witt (PBW) type in the sense of [17] (see also [18]). These results are generalised for any Coxeter root system $R$ in the final section.

We also consider the $gl(N)$ version of the subalgebra of the rational Cherednik algebra which is generated by the elements $x_kD_l$ rather than their combinations $M_{kl}$, and by the group algebra. A closely related algebra in type $A_{N-1}$ was considered in [19]. We describe relations in this algebra too and it gives another example of a non-homogeneous quadratic algebra of PBW type.

II. ANGULAR CALOGERO-MOSER HAMILTONIAN

We will work with the gauged Dunkl operators defined by

\begin{equation}
\nabla_i = \partial_i - \sum_{j=1}^{N} \frac{g}{x_i - x_j} s_{ij}.
\end{equation}

They correspond to (1.1) via the transformation $\psi \to \prod_{i<j}(x_i - x_j)^\theta \psi$ of the wavefunctions. Applying them instead of usual momenta operators for the free-particle system, we arrive
at the modified Hamiltonian \[4\]

\[
H = -\frac{1}{2} \sum_{i=1}^{N} \nabla_i^2 = -\frac{1}{2} \sum_{i=1}^{N} \partial_i^2 + \sum_{i<j} \frac{g(g - s_{ij})}{(x_i - x_j)^2}.
\]  

(2.2)

Let now \(\text{Res}(A) \equiv \text{Res}_+(A)\) be the restriction of an \(S_N\)-invariant operator \(A\) to the space of symmetric functions, and let \(\text{Res}_-(A)\) be its restriction to the antisymmetric functions. Then

\[
\text{Res}_\pm H = H_\pm,
\]

(2.3)

where \(H_\pm\) is the Calogero–Moser Hamiltonian \[5\]:

\[
H_\pm = -\frac{1}{2} \sum_{i=1}^{N} \partial_i^2 + \sum_{i<j} \frac{g(g \mp 1)}{(x_i - x_j)^2}.
\]

(2.4)

Apart from \(g = 0\) case, when the algebra generated by \(\nabla_i, x_j\) reduces to the Heisenberg algebra, the algebra formed by the coordinates and Dunkl operators for \(g \neq 0\) is not closed:

\[
[\nabla_i, x_j] = S_{ij}, \quad [\nabla_i, \nabla_j] = 0, \quad [x_i, x_j] = 0,
\]

(2.5)

where for the later convenience the pairwise permutation operators are rescaled and the new notation \(S_{ij}\) is introduced:

\[
S_{ij} = \begin{cases} 
-gs_{ij}, & \text{for } i \neq j, \\
1 + g \sum_{k \neq i} s_{ik} = 1 - \sum_{k \neq i} S_{ik}, & \text{for } i = j. 
\end{cases}
\]

(2.6)

Introduce spherical coordinates and let \(H_\Omega, H_\Omega,\pm\) be the corresponding angular Calogero–Moser Hamiltonians obtained by the separation of radial and angular variables:

\[
H = -\frac{\partial_r^2}{2} - \frac{N - 1}{2r} \partial_r + H_\Omega, \\
H_\pm = -\frac{\partial_r^2}{2} - \frac{N - 1}{2r} \partial_r + H_{\Omega,\pm}.
\]

(2.7)

(2.8)

Define Dunkl angular momentum operators

\[
M_{kl} = x_k \nabla_l - x_l \nabla_k.
\]

(2.9)

It appears that the operators \(M_{kl}\) allow to express the angular Hamiltonian in analogy with the formula (2.3) for the usual Calogero-Moser Hamiltonian.
Proposition 1. The angular Hamiltonians can be obtained as

\[ H_{\Omega} = -\frac{1}{2} M^2 + \frac{1}{2} S(S - N + 2), \]  \hspace{1cm} (2.10)

\[ H_{\Omega,\pm} = \text{Res}_{\pm} H_{\Omega} = -\frac{1}{2} M^2 + \gamma_{\pm}, \quad \gamma_{\pm} = gN(N - 1) \frac{gN(N - 1) \pm 2(N - 2)}{8}, \]  \hspace{1cm} (2.11)

where we define the Dunkl angular momentum square and the symmetric group algebra invariant operators, respectively, as

\[ M^2 = \sum_{i<j} M^2_{ij}, \]  \hspace{1cm} (2.12)

\[ S = \sum_{i<j} S_{ij}. \]  \hspace{1cm} (2.13)

Proof. The proposition is a consequence of the following relation

\[ M^2 = x^2 \nabla^2 - (x \cdot \nabla)^2 + (2S - N + 2)(x \cdot \nabla), \]  \hspace{1cm} (2.14)

where we use the usual vector and scalar product notations.

Indeed, using \( x^2 = r^2 \) and substituting

\[ x \cdot \nabla = x \cdot \partial + S = r \partial_r + S \]

into (2.14), we obtain

\[ M^2 = r^2 \nabla^2 - r^2 \partial_r^2 - (N - 1)r \partial_r + S(S - N + 2). \]

This relation together with (2.13) and (2.7) proves the desired expression (2.10) for the spherical Hamiltonian. Its restriction for bosons (fermions) (2.11), corresponding to the pure Calogero model, is obtained from

\[ \text{Res}_{\pm} S = \mp g \frac{N(N - 1)}{2}. \]

In order to complete the proof, we have to justify the relation (2.14). Substituting (2.9) into (2.12) and using the commutation relations (2.5), we have:

\[ M^2 = \sum_{k,l} (x_k \nabla_l x_k \nabla_l - x_l \nabla_k x_k \nabla_l) \]

\[ = x^2 \nabla^2 - (x \cdot \nabla)^2 + \sum_{k,l} (x_k S_{kl} \nabla_l + S_{kl} x_k \nabla_l - S_{kk} x_l \nabla_l) \]

\[ = x^2 \nabla^2 - (x \cdot \nabla)^2 + (2S - N)(x \cdot \nabla) + \sum_{k,l} (x_k S_{kl} + S_{kl} x_k) \nabla_l. \]  \hspace{1cm} (2.15)
The last term can be simplified further by rewriting the definition (2.6) of $S_{ij}$ in the generating function form

$$
\sum_k S_{lk} x_k = x_l + \sum_{k \neq l} S_{lk} (x_k - x_l).
$$

(2.16)

Its application leads to the following identity:

$$
\sum_k \{S_{lk}, x_k\} = 2x_l + \sum_{k \neq l} \{S_{lk}, x_l - x_k\} = 2x_l.
$$

(2.17)

By substituting (2.17) into (2.15) we get the desired expression (2.14). This completes the proof.

We mention that a related statement in the case of Dunkl operators associated with the group $\mathbb{Z}_2^N$ is contained in [20].

### III. DUNKL ANGULAR MOMENTA ALGEBRA

Recall that the creation-annihilation operators $a_i^+, a_i^- \equiv a_i$ for the Calogero–Moser rational model in the harmonic confinement [7], [6] are given by

$$
a_i^\pm = \frac{\sqrt{2}}{2} (x_i \mp \nabla_i).
$$

(3.1)

They satisfy the relations

$$
[a_i, a_j^+] = S_{ij}, \quad [a_i, a_j] = [a_i^+, a_j^+] = 0
$$

(3.2)

and are hermitian conjugate to each other. This coincides with the relations (2.5) for the operators $x_i, \nabla_j$ via the correspondence

$$
a_i^+ \leftrightarrow x_i, \quad a_i \leftrightarrow \nabla_i.
$$

(3.3)

The commutation relations between creation-annihilation operators and group elements have the form

$$
S_{ij} a_i^\pm = a_j^\pm S_{ij}, \quad [S_{ij}, a_k^+] = 0 \quad \text{with} \quad i \neq j \neq k \neq i.
$$

(3.4)

Recall also that

$$
S_{ij} S_{ik} = S_{jk} S_{ij}, \quad [S_{ij}, S_{kl}] = 0, \quad S_{ij}^2 = g^2, \quad S_{ij} = S_{ji}.
$$

(3.5)
where differently denoted indexes are assumed again to have different values, and it follows that

\[ S_{ij}S_{jj} = S_{ii}S_{jj}, \quad [S_{ij}, S_{kk}] = 0. \quad (3.6) \]

The deformed angular momentum generators (2.9) are expressed in terms of the deformed creation-annihilation operators (3.1) as

\[ M_{kl} = a_k^+ a_l - a_l^+ a_k. \quad (3.7) \]

They inherit the standard (anti-)commutation relations with the permutations operators:

\[ [S_{ij}, M_{kl}] = 0, \quad \{S_{ij}, M_{ij}\} = 0, \quad S_{ij}M_{ik} = M_{jk}S_{ij}, \quad (3.8) \]

provided that differently denoted indexes have different values.

When the deformation parameter \( g \) vanishes, (3.7) corresponds to the standard representation of the generators of the algebra \( so(N) \) in terms of bosonic creation-annihilation operators or vector fields. In this case, the corresponding operators \( M_{ij}^0 \) satisfy the well known commutation relation

\[ [M_{ij}^0, M_{kl}^0] = M_{il}^0\delta_{jk} + M_{jk}^0\delta_{il} - M_{ik}^0\delta_{lj} - M_{jl}^0\delta_{ik}. \quad (3.9) \]

For nontrivial values of the deformation parameter, these generators, like \( a_i^\pm \) themselves, do not form a Lie algebra any more, since their commutators include the coefficients dependent on the permutation operators.

We are interested in the Dunkl angular momenta algebra \( H_g^{so(N)} \) which is generated by the operators \( M_{kl} \) and by the group algebra \( \mathbb{C}S_N \). It can be considered as a subalgebra of the rational Cherednik algebra \( H_g(S_N) \) via the homomorphism which maps generators \( M_{kl} \to x_k D_l - x_l D_k \).

To get the commutators between the operators \( M_{ij} \), one just replaces the Euclidean metric \( \delta_{ij} \) in (3.9) by the permutation operator \( S_{ij} \). This matches the deformation rules in the commutators given by (2.5) or (3.2). More precisely, the following statement takes place whose version in another gauge is contained in \([16]\) (Section 8, arXiv version only).

**Proposition 2.** (cf. \([16]\)) Operators (3.7) satisfy the following commutation relations:

\[ [M_{ij}, M_{kl}] = M_{il}S_{jk} + M_{jk}S_{il} - M_{ik}S_{lj} - M_{jl}S_{ik}, \quad (3.10) \]

where \( 1 \leq i, j, k, l \leq N \).
Proof. In order to prove (3.10), firstly, we verify the commutators

\[ [a_i^+ a_j, a_k^+ a_l] = a_i^+ S_{jk} a_l - a_k^+ S_{il} a_j, \]

which is a simple consequence of the relations (3.2). Then using them together with the definition (3.7), we get

\[ [M_{ij}, M_{kl}] = \text{asym}(a_i^+ S_{jk} a_l - a_k^+ S_{il} a_j) = \text{asym}(a_i^+ S_{jk} a_l - a_i^+ S_{jk} a_i), \]  

(3.11)

where in order to shorten the formulae, we introduce the operator, which antisymmetrizes over the pairs of indexes included in square brackets:

\[ \text{asym}_{[ij]} A_{ij} := A_{ij} - A_{ji}. \]  

(3.12)

The simplest case is when the values of all four indices differ. Then permutation operators commute with the annihilation-creation operators in all terms, and we arrive at the desired commutation relation (3.10).

It remains to consider the less trivial case when only three indexes differ. It is sufficient to check \( k = j \) case only. Then (3.11) acquires the following form:

\[ [M_{ij}, M_{jl}] = \text{asym}(a_i^+ S_{jj} a_l - a_i^+ S_{jl} a_j) \]
\[ = a_i^+ S_{jj} a_l - a_j^+ S_{jj} a_j - a_i^+ S_{jj} a_j - a_i^+ S_{jj} a_i + a_i^+ S_{ij} a_i + a_j^+ S_{ij} a_i \]  

(3.13)

Then moving permutations to the right in order to get the desirable result, the additional commutators appear in contrast to the previous case. However, such unwanted terms are canceled out. Indeed, the only nontrivial commutations between permutations and creation-annihilation operators are given by

\[ [S_{jj}, a_i^+] = [S_{ij}, a_j^+] = (a_i^+ - a_j^+) S_{ij}, \]  

(3.14)

\[ [S_{jj}, a_j^+] = \sum_{k \neq j} (a_j^+ - a_k^+) S_{kj}, \]  

(3.15)

as can be deduced from the definition (2.6). Due to (3.14), the appeared commutators eliminate each other:

\[ a_i^+ ([S_{jj}, a_i] - [S_{jl}, a_j]) - a_i^+ ([S_{jj}, a_i] - [S_{ij}, a_j]) = 0. \]

Therefore, the commutation relation (3.10) holds for arbitrary index values, and we have finished its proof. \( \square \)
The relation (3.10) is reduced to the usual commutation (3.9) for $so(N)$ generators in the nondeformed limit $g = 0$.

The order of operators $S_{ij}$ and $M_{kl}$ in the right-hand side of the equation (3.10) must be respected in general. Using the relations (3.8), some permutations in the right-hand side of the commutator (3.10) can be moved to the left of the Dunkl angular momenta generators. In particular, if all the indexes differ then the operators commute but, in general case, the obtained in this way relations will be more complicate. However, it is easy to verify that all permutations can be moved to the left simultaneously:

$$[M_{ij}, M_{kl}] = S_{jk}M_{il} + S_{il}M_{jk} - S_{ij}M_{ik} - S_{ik}M_{jl}.\quad (3.16)$$

The above relation follows also from the invariance of the subalgebra $H_g^{so(N)}$ under the Hermitian conjugation,

$$M_{ij} = -M_{ij}, \quad S_{ij} = S_{ij}, \quad (3.17)$$

which is inherited from the bigger algebra $H_g(S_N)$.

We also note the equivariance of the relations (3.10), (3.16) under the symmetric group action. It is easy to verify using the relations (3.8), (3.5), and (3.6) that any permutation $\sigma \in S_N$, when acting on the commutator (3.10), just permutes all its indexes: $i \rightarrow \sigma(i)$.

IV. CROSSING RELATION AND PBW PROPERTY

Let us establish another quadratic relation, which the generators of the deformed angular momentum algebra $H_g^{so(N)}$ satisfy. We call it the crossing relation.

**Proposition 3.** The deformed angular momentum operators (3.7) satisfy the following crossing relations:

$$M_{ij} M_{kl} + M_{jk} M_{il} + M_{ki} M_{jl} = M_{ij} S_{kl} + M_{jk} S_{il} + M_{ki} S_{jl}, \quad (4.1)$$

where $1 \leq i, j, k, l \leq N$.

**Proof.** Note that in both sides of the relation (4.1) the sum is taken over the cyclic permutations of the first three indexes $i, j, k$, so that it can be rewritten as

$$\text{cyclic } M_{ij} M_{kl} = \text{cyclic } M_{ij} S_{kl}, \quad (4.2)$$
where for convenience the cyclic permutation sum operator is introduced:

\[
\text{cyclic } A_{ijk} := A_{ijk} + A_{jki} + A_{kij}. \quad (4.3)
\]

Note that the right-hand side of the equality (4.1) contains the terms, which appear also in the right-hand side of the commutation relation (3.10). It is easy to verify that if the values of any two of the indexes \(i, j, k, l\) coincide, then the relation (4.1) either reduces to the commutation relation, or its both side vanish trivially. Therefore, it is enough to consider the case when the values of all four indexes differ.

Define the usual normal order \(\mathcal{N}()\) with the creation operators placed on the left hand side and annihilation operators on the right. For instance, \(\mathcal{N}(a_+^i a_j a_+^k a_l) = a_+^i a_+^j a_+^k a_l\). The operators commute under the normal order: \(\mathcal{N}([M_{ij}, M_{kl}]) = 0\). Since the classical momenta obey the crossing relations, the same relation holds also for the normal order:

\[
\mathcal{N}(M_{ij} M_{kl} + M_{jk} M_{il} + M_{ki} M_{jl}) = 0. \quad (4.4)
\]

Using the definition (3.7), one can express each product in terms of the normal order as

\[
M_{ij} M_{kl} = \mathcal{N}(M_{ij} M_{kl}) + \text{asym} a_+^i a_i S_{jk}.
\]

Therefore, the right hand side of the crossing relation equals

\[
M_{ij} M_{kl} + M_{jk} M_{il} + M_{ki} M_{jl} = a_+^i a_l S_{jk} + a_+^j a_k S_{il} - a_+^j a_l S_{ik} - a_+^i a_k S_{jl}
\]

\[
= a_+^j a_l S_{ki} + a_+^k a_i S_{jl} - a_+^k a_l S_{ij} - a_+^i a_j S_{kl}
\]

\[
= a_+^k a_i S_{ij} + a_+^i a_j S_{kl} - a_+^i a_k S_{kj} - a_+^k a_j S_{il}
\]

Canceling out and grouping together similar terms, we arrive at the desired expression (4.1).

Note that all the permutation operators in the right-hand side of the crossing relations can be moved in front of the angular momentum operators:

\[
\text{cyclic } M_{ij} M_{kl} = \text{cyclic } S_{kl} M_{ij}. \quad (4.5)
\]

In the the case of two equal indexes the relations (4.2) and (4.5) are reduced to the commutation relations (3.10) and (3.16) respectively, whose equivalence is already established.
Applying the hermitian conjugate to the crossing relations (4.1) and using (3.17), we obtain the equivalent relations

\[
\text{cyclic } M_{\ell i}M_{jk} = \text{cyclic } S_{\ell i}M_{jk} = \text{cyclic } M_{ij}S_{kl} = \text{cyclic } M_{ij}M_{kl}.
\]  

(4.6)

Like for the commutators, the system of crossing relations (4.6) is invariant with respect to the permutation group.

The sum of the equations (4.2) and (4.5) gives rise to a simpler crossing relation written in terms of anticommutators with vanishing right-hand side:

\[
\text{cyclic } \{M_{ij},M_{kl}\} = 0.
\]  

(4.7)

This is the analogue of the crossing relations in quantum case, which possesses the same symmetry as the classical one. Its direct consequence is the vanishing of antisymmetrized product

\[
\text{asym } M_{ij}M_{kl} = 0.
\]  

(4.8)

For even values of \(N\), this results in vanishing of the Pfaffian

\[
\sum_{i_1...i_N} \varepsilon_{i_1...i_N} M_{i_1i_2}M_{i_3i_4}...M_{i_{N-1}i_N} = 0,
\]  

(4.9)

which corresponds to a peculiar Casimir elements of \(so(N)\) Lie algebra. Here \(\varepsilon_{i_1...i_N}\) is the Levi-Civita anti-symmetric tensor.

The crossing relation has a clear graphical interpretation. We represent the Dunkl angular momentum tensor \(M_{ij}\) by an arrow with tensor indexes at endpoints as shown on Figure 1.

The permutation operator \(S_{ij}\) is depicted by a dashed bond. Then the Figure 2 describes schematically the crossing relation (4.1). Each of six terms from the first equation is a product of two operators taken in a certain quantum order: the operator, containing the index \(l\) is positioned on the right side. The ordering is not essential when we omit the first-order terms in momenta, as shown in the second equation on the Figure.

Now we are going to show that all other relations in the algebra \(H_g^{so(N)}\) follow from the ones already established. Let us consider an abstract associative algebra \(\mathcal{A}\) over \(\mathbb{C}\).
FIG. 2. Graphical representation of the crossing relations (4.1). Each term is a product of two operators from Figure 1, with one with index \( l \) positioned on the right. The change of the operator order affects the right-hand side of the first equality only, and it is not essential for the second equality.

generated by elements \( M_{ij} \) and by the symmetric group algebra \( \mathbb{C}S_N \) such that the relations (3.8), (3.10), (4.1) are imposed, as well as \( M_{ji} = -M_{ij} \). We are interested in a linear basis of this algebra.

Consider the monomials composed from deformed angular momenta and pairwise permutations. Then using the commutation relations (3.8), the permutations can be moved to the right giving rise to

\[
M_{i_1j_1}^{n_1} \cdots M_{i_kj_k}^{n_k} \sigma \quad \text{with} \quad i_s < j_s, \quad n_s > 0, \quad k \geq 0, \quad \sigma \in S_N. \tag{4.10}
\]

The induction on \( n = \sum_{s=1}^{k} n_s \) and the commutation relation (3.10) ensure a rearrangement of the elements \( M_{i_s,j_s} \) in (4.10) according to some predefined order. Thus we choose the indexes to be ordered first by the values of \( i_s \), then, if they equal, by the values of \( j_s \):

\[
\begin{align*}
i_1 \leq \ldots \leq i_k, \quad \text{and} \quad i_s = i_{s+1} & \implies j_s < j_{s+1}. \tag{4.11}
\end{align*}
\]

However, the ordered monomials are still not linearly independent. There is an additional restriction imposed by the crossing relations (4.1), which survives in the classical case too and can be easily formulated using the graphical representation.

Let us mark points 1, 2, \ldots, \( N \) on the real line and connect the pairs \((i_s, j_s)\) by \( n_s \) directed semicircles in the upper half-plane. We get in this way the graphical representation of the angular momentum part of the monomial (4.10), see an example on Figure 3. Then the crossing bonds can be untangled by successive application of the crossing relation, which is
FIG. 3. Graphical representation of a sample monomial, which does not contain intersecting angular momentum bonds.

represented on Figure 2. Therefore, we arrive at the set of monomials, which do not have intersecting semicircles, that is they satisfy the condition

\[ i_s < i_s' < j_s \quad \Rightarrow \quad j_s' \leq j_s. \]  \tag{4.12}

Let \( V \) be a vector space of dimension \( N \) with the basis \( e_1, \ldots, e_N \). Let \( \Lambda^2 V \) be the second exterior power of \( V \). Consider the tensor algebra \( T(\Lambda^2 V) \) and its smash product with the symmetric group algebra \( \mathbb{C}S_N \) where group elements act on \( V \) and hence on \( \Lambda^2 V \) by permuting the basis elements. We view operators \( M_{ij} \) as elements of this smash product \( T(\Lambda^2 V) \# \mathbb{C}S_N \) via the mapping \( M_{ij} \rightarrow (e_i \otimes e_j - e_j \otimes e_i)e \), where \( e \in S_N \) is the identity element.

**Theorem 4.** The deformation \( H_{g}^{\text{so}(N)} \) is an associative algebra over \( \mathbb{C} \) which is the quotient of the algebra \( T(\Lambda^2 V) \# \mathbb{C}S_N \) over the relations (3.10), (4.1). The set of monomials (4.10) with the restrictions (4.11), (4.12) gives a basis of the algebra \( H_{g}^{\text{so}(N)} \) for any \( g \in \mathbb{C} \).

**Proof.** It is easy to see in the representation (2.9) that monomials (4.10) with the restrictions (4.11) and (4.12), are linearly independent for \( g = 0 \). Moreover their classical version, when \( M_{ij} \) is replaced with the classical angular momenta

\[ M_{ij}^{\text{cl}} = x_ip_j - x_jp_i, \]  \tag{4.13}

are linearly independent too (see e.g. [11]). By taking the highest symbols, considered as elements of the smash product algebra \( \mathbb{C}[x,p] \# S_N \), it follows that these monomials are linearly independent for any \( g \).

Theorem 4 and its proof show that \( H_{g}^{\text{so}(N)} \) is a flat family of nonhomogeneous quadratic algebras over \( \mathbb{C}S_N \) of Poincaré–Birkhoff–Witt type in the terminology of [17] (see also [8], [18]).
Note that the constructed non-intersection monomial basis is similar to the well-known overcomplete valence-bond basis among the singlet states for usual quantum spins, introduced by Temperley and Lieb and subjecting to the similar crossing relations (with the trivial right-hand side) [21].

V. THE CENTRE

Consider the square of the Dunkl angular momentum operator $M^2$ given by (2.12), which is an analogue of the second order Casimir element of the usual $so(N)$ algebra. Evidently, it is invariant with respect to the permutations $S_{ij}$. However, it commutes with all the elements $M_{ij}$ only in the limit $g = 0$. In order to obtain a true central element, the operator (2.12) must be supplemented by an element from the symmetric group algebra. Such an operator appeared in [16]. We show that this operator generates the whole centre. Based on Proposition 1 this element can be identified with the angular Calogero–Moser Hamiltonian.

**Theorem 5.** The angular Hamiltonian (2.10) is invariant with respect to the algebra $H_{g^{so(N)}}$, that is it belongs to its centre $Z$:

\[
[H_\Omega, M_{ij}] = 0, \quad [H_\Omega, S_{ij}] = 0.
\]  

(5.1)

Furthermore, $Z$ is generated by $H_\Omega$ and constants.

**Proof.** The second equation in (5.1) reflects the fact that $S$ lies in the center of the symmetric group algebra: $[S, S_{ij}] = 0$.

First we prove that the original Hamiltonian is invariant with respect to the algebra $H_{g^{so(N)}}$. Since its invariance with respect to the particle permutations is evident, it remains to verify

\[
[H, M_{ij}] = [\nabla^2, M_{ij}] = 0.
\]

(5.2)

Indeed, as is argued in the proof of Proposition 1, the relation (2.17) remains valid upon the substitution $x_i \rightarrow \nabla_i$:

\[
\sum_k \{S_{ik}, \nabla_k\} = 2\nabla_i.
\]

(5.3)

As a consequence, we obtain the relation (5.2) using also the commutations (2.5):
where we have used the index antisymmetrization (3.12) for the convenience.

Then we note that the Dunkl angular momentum operators (2.9), (2.1) depend on angular coordinates only. This becomes evident after the application of the involutive antiautomorphism of the Cherednik algebra with the mutual exchange of \( x_i \) and \( \nabla_i \), to the equation (5.2):

\[
[x^2, M_{ij}] = [r^2, M_{ij}] = 0.
\] (5.4)

Together with (5.2) and the expression of the Hamiltonian in spherical coordinates (2.7), it implies that the angular Hamiltonian (2.2) preserves the Dunkl angular momentum, i.e. the first relation in (5.1).

Consider now an arbitrary element \( B \in Z \). Let \( B_0 \in \mathbb{C}[x, p] \# S_N \) be its highest symbol \( Sym(B) \) in the smash product algebra of polynomials in coordinates \( x_1, \ldots, x_N \) and momenta \( p_1, \ldots, p_N \), and the symmetric group. Let \( d \geq 0 \) be its degree in \( x \) or \( p \) variables. Note that \( B_0 \) does not contain non-trivial group elements. Indeed, consider the decomposition of \( B \) with regard to the basis as in Theorem 4. Suppose that a term with \( \sigma \in S_N, \sigma \neq 1 \) arises in the highest degree. By taking \( M_{ij} \) such that \( \sigma(M_{ij}) \neq M_{ij} \) we get that

\[
\deg Sym[B, M_{ij}] = d + 1,
\]

so the commutator cannot be zero.

Consider now the commutator \([B, M_{ij}]\) for an arbitrary \( M_{ij} \). Note that the terms in its symbol of degree \( d \), which do not contain non-trivial group elements, coincide with the classical Poisson commutator of \( B_0 \) and the usual classical angular momentum (4.13), which is zero. The Poisson centre of the algebra generated by the classical angular momenta \( M_{ij}^{cl} \) is generated by \( \sum_{i<j}(M_{ij}^{cl})^2 \) (this can be derived, for instance, from the results of [23]). The rest follows by subtracting the corresponding power of \( H_{\Omega} \) from \( B \) and by inductive reducing the degree of \( B \).

VI. EXAMPLE: DEFORMATION OF \( so(3) \) ALGEBRA

Consider now the simplest case of the \( H_g^{so(3)} \) algebra, which describes a deformation of the usual three-dimensional quantum angular momentum operators. Define

\[
M_1 = M_{23}, \quad M_2 = M_{31}, \quad M_3 = M_{12},
\]

\[
S_1 = S_{23}, \quad S_2 = S_{31}, \quad S_3 = S_{12}.
\]
Then the commutation relations (3.5) and (3.8) between the generators take the form

\[ S_1 S_2 = S_3 S_1, \quad S_1^2 = g^2, \]
\[ \{S_1, M_1\} = 0, \quad S_1 M_2 = -M_3 S_1, \quad S_1 M_3 = -M_2 S_1 \]

and their cyclic permutations.

The commutation relations (3.10) are equivalent to

\[ [M_1, M_2] = -M_3 + (M_3 - M_2) S_1 + (M_3 - M_1) S_2 \]

and other relations are obtained by the cyclic permutations of three indexes. They can be rewritten in a more symmetric form,

\[ [M_1, M_2] = -M_3 + \{M_3, S_1 + S_2\}. \]

The Casimir element, which is proportional to the angular Hamiltonian, has the following form in terms of introduced operators:

\[ H_\Omega \sim M_1^2 + M_2^2 + M_3^2 - S(S - 1), \quad S = S_1 + S_2 + S_3. \]

It extends the spin square operator.

Note that for so(3) case the crossing relations are either trivial or reduce to the commutation relations.

VII. \textit{gl}(N) \textbf{C}A\textbf{S}E

The algebra \( H^\text{so}(N) \) can be included into a bigger subalgebra \( H^\text{gl}(N) \) of the rational Cherednik algebra. We define it to be generated by the operators

\[ E_{kl} = a^+_k a_l \quad \text{(7.1)} \]

and by the group algebra \( \mathbb{C}S_N \) \((1 \leq k, l \leq N)\). The operators can be considered acting on meromorphic functions. We also have \( M_{kl} = E_{kl} - E_{lk} \).

The algebra can be realised as a subalgebra of the rational Cherednik algebra \( H_\beta(S_N) \) via a conjugation which maps \( \nabla_k \to D_k \). Further, there are more general but equivalent choices of the generators \( \widetilde{E}_{kl} = (\alpha x_k + \beta \nabla_k)(\gamma x_l + \delta \nabla_l) \), where parameters \( \alpha, \beta, \gamma, \delta \) are such that \( \alpha \delta - \beta \gamma \neq 0 \). They define isomorphic algebras. Indeed, the operators \( \alpha x_k + \beta \nabla_k \) with
different indices \(k\) pairwise commute. Therefore these generators correspond to different choices of generators of the rational Cherednik algebra. In particular, the algebra \(H_g^{gl(N)}\) is isomorphic to the subalgebra of the rational Cherednik algebra \(H_g(S_N)\) which is generated by the elements \(x_kD_l\) and by the group algebra \(\mathbb{C}S_N\).

Generators \(E_{kl}\) obey the standard commutation relations with the permutation operators:

\[
[S_{ij}, E_{kl}] = 0, \quad S_{ij}E_{ij} = E_{ji}S_{ij}, \quad S_{ij}E_{ik} = E_{jk}S_{ij}, \quad S_{ij}E_{ki} = E_{kj}S_{ij},
\]

(7.2)

where all indexes are pairwise different.

As in the case of the usual \(gl(N)\), the rising and lowering generators are Hermitian conjugate of each other:

\[
E_{ij}^+ = E_{ji}, \quad S_{ij}^+ = S_{ij}.
\]

(7.3)

We start from the analogue of the crossing relation (4.1), which in this case takes the following form:

\[
E_{ij}E_{kl} - E_{il}E_{kj} = E_{il}S_{jk} - E_{ij}S_{kl}.
\]

(7.4)

For different values of \(i, j, k\) this relation follows immediately from (7.1) and (3.2), (3.4).

The nontrivial case is when \(j = k \neq l\), for which we have:

\[
E_{ij}E_{kl} - E_{il}E_{kj} = a_i^+S_{jj}a_l - a_i^+S_{lj}a_j = E_{il}S_{jj} + (E_{il} - E_{ij})S_{lj} - E_{il}S_{lj}
\]

where in the second equality above the relation (3.14) was applied.

Taking the Hermitian conjugate of (7.4), we get an equivalent relation, with antisymmetrization over the first indexes of \(E_{ij}\) generators. Both relations can be written down in the following compact form:

\[
\text{asym} E_{ij}(E_{kl} + S_{kl}) = \text{asym}(E_{ij} + S_{ij})E_{kl} = 0.
\]

(7.5)

Their combination with suitably chosen indexes results in the commutation relation among the deformed \(gl(N)\) generators

\[
[E_{ij}, E_{kl}] = E_{il}S_{jk} - S_{il}E_{kj} + [S_{kl}, E_{ij}],
\]

(7.6)

which holds for any index values. Its antisymmetrisation over \(i, j\) and \(k, l\) immediately gives the commutation relations (3.10) for deformed angular momenta. When all indexes differ, the commutator in the right-hand side of (7.6) disappears, and we arrive at a natural
extension of \( gl(N) \) commutation relations with metrics tensor \( \delta_{ij} \) replaced by the pairwise permutation operator \( S_{ij} \), as for the \( so(N) \) case considered above. Some other commutation relations are less straightforward. Below we write down all particular cases of the commutation relation (7.6) provided that the values of all four indexes differ pairwise.

\[
\begin{align*}
[E_{ij}, E_{kl}] &= E_{il}S_{jk} - E_{kl}S_{ij}, \\
[E_{ii}, E_{kl}] &= E_{il}S_{ik} - E_{kl}S_{ii}, \\
[E_{ii}, E_{jj}] &= (E_{ii} - E_{jj})S_{ij}, \\
[E_{ij}, E_{ij}] &= E_{il}S_{ij} - E_{ij}S_{il}, \\
[E_{ij}, E_{ji}] &= E_{ii}S_{jj} - E_{jj}S_{ii} + (E_{ii} - E_{jj} - E_{ij} + E_{ji})S_{ij},
\end{align*}
\]

(7.7)

and the equalities from the third line in (7.7) must also be supplemented by their conjugate relations. As for \( H_{g}^{so(N)} \) case, considered above, any monomial in \( E_{ij} \) and \( S_{ij} \) can be expressed in the following form by moving all permutations to the right hand side:

\[
E_{i_{1}j_{1}}^{n_{1}} \cdots E_{i_{k}j_{k}}^{n_{k}} \sigma, \quad \sigma \in S_{N},
\]

(7.8)

where \( k \geq 0, n_{1}, \ldots, n_{k} > 0 \). Due to relations (7.4)–(7.6), any such monomial can be linearly expressed in terms of the monomials, where both index sets \( \{i_{s}\} \) and \( \{j_{s}\} \) are ordered in some way, for example

\[
i_{1} \leq \ldots \leq i_{k} \quad \text{and} \quad j_{1} \leq \ldots \leq j_{k}.
\]

(7.9)

Using the Wicks’s theorem, one can decompose (7.8) as was described in Section IV. In the example below, only the highest-order term in this normal ordering decomposition is shown

\[
E_{11}^{n_{1}}E_{12}^{n_{2}}E_{22}^{n_{3}}E_{32}^{n_{4}}E_{33}^{n_{5}}E_{34}^{n_{6}} = (a_{1}^{+})^{n_{1}+n_{2}}(a_{2}^{+})^{n_{3}}(a_{3}^{+})^{n_{4}+n_{5}+n_{6}}a_{1}^{n_{1}}a_{2}^{n_{2}+n_{3}+n_{4}}a_{3}^{n_{5}}a_{4}^{n_{6}} + \ldots.
\]

Here the lower-order terms in \( a_{i}^{\pm} \) are indicated by the dots.

The monomials (7.8) with the restriction (7.9) are linearly independent, since it is easy to see that there is a one-to-one correspondence between them and their “highest symbols”

\[
a_{i_{1}}^{+n_{1}} \cdots a_{i_{k}}^{+n_{k}} a_{j_{1}}^{n_{1}} \cdots a_{j_{k}}^{n_{k}},
\]

and because of the PBW theorem for the rational Cherednik algebra [8].

Let \( V \) be a vector space of dimension \( N \) with the basis \( e_{1}, \ldots, e_{N} \). Consider the tensor algebra \( T(V \otimes V) \) and its smash product with the symmetric group algebra \( \mathbb{C}S_{N} \) where group
elements act on $V$ and hence on $V \otimes V$ by permuting the basis elements. We view operators $E_{ij}$ as elements of this smash product $T(V \otimes V) \# \mathbb{C}S_N$ via the mapping $E_{ij} \to (e_i \otimes e_j)e$, where $e \in S_N$ is the identity element.

Similarly to the case of $H_g^{so(N)}$ we have the following statement which implies that $H_g^{gl(N)}$ is a flat family of nonhomogeneous quadratic algebras of Poincaré–Birkhoff–Witt type.

**Theorem 6.** The deformation $H_g^{gl(N)}$ is an associative algebra over $\mathbb{C}$ which is the quotient of the algebra $T(V \otimes V) \# \mathbb{C}S_N$ over the relations (7.5). The set of monomials (7.8) with the restriction (7.9) gives a basis of the algebra $H_g^{gl(N)}$ for any $g \in \mathbb{C}$.

From the commutation relations (7.6) it is easy to deduce that the element

$$\rho = \sum_i E_{ii} - S = \sum_i a_i^+ a_i - S, \quad (7.10)$$

$S = \sum_{i<j} S_{ij}$, commutes with the entire algebra $H_g^{gl(N)}$. It describes the Calogero Hamiltonian (2.11) in confined oscillator potential [2], which can be seen from (2.2) and (3.1) [7]:

$$\rho = H + \frac{1}{2}x^2 - \frac{N}{2},$$

$$\text{Res}_\pm \rho = H_\pm + \frac{1}{2}x^2 - \frac{N}{2}. \quad (7.11)$$

Therefore, the algebra $H_g^{gl(N)}$ describes the invariants of the Calogero-Moser Hamiltonian

$$\frac{1}{2} \sum_{i=1}^N (-\partial_i^2 + x_i^2) + \sum_{i<j} g(g - s_{ij}) (x_i - x_j)^2,$$

extended out of the space of identical particles.

Finally we note that $\rho$ and constants generate the centre of $H_g^{gl(N)}$. This follows from the following lemma similarly to the proof of Theorem 5.

**Lemma 1.** Consider the classical Poisson algebra generated by $E_{ij}^{cl} = x_i p_j \ (1 \leq i, j \leq N)$ with the standard Poisson bracket. Then $C = \sum_{i=1}^N x_i p_i$ generates the centre $Z$ of the algebra.

**Proof.** Let $f(x, p) \in Z$. Since the Poisson bracket

$$\{x_i p_j, f\} = (x_i \partial_{x_j} - p_j \partial_{p_i}) f = 0 \quad (7.12)$$

it follows for $i = j$ that $f$ is a function of the variables $y_i = x_i p_i \ (1 \leq i \leq N)$. In these variables, the relation (7.12) implies that $(\partial_{y_i} - \partial_{y_j}) f = 0$ so that $f$ is a function of $C = \sum y_i$ as stated. \qed
VIII. COXETER GROUPS GENERALISATIONS

The previous results can be generalised to the case when the symmetric group $S_N$ is replaced with a finite reflection group.

Let $R$ be a Coxeter root system in the Euclidean space $V \cong \mathbb{R}^N$ with the inner product denoted as $(\cdot, \cdot)$ (see [22]). Let $e_1, \ldots, e_N$ be the standard basis. Denote by $s_\alpha$ the orthogonal reflection with respect to the hyperplane $(\alpha, x) = 0$:

$$s_\alpha x = x - \frac{2(\alpha, x)}{(\alpha, \alpha)} \alpha,$$

where $x = \sum x_i e_i \in V$. Let $W$ be the corresponding finite Coxeter group generated by reflections $s_\alpha, \alpha \in R$. Let $g : R \to \mathbb{C}$ be a $W$-invariant function, denote $g_\alpha = g(\alpha)$.

The Dunkl operators take the form

$$\nabla_\xi = \partial_\xi - \sum_{\alpha \in R_+} \frac{g_\alpha(\alpha, \xi)}{(\alpha, x)} s_\alpha,$$

where $\xi \in \mathbb{R}^N$, and $R_+$ is a positive half of the root system. Given $\xi, \eta \in \mathbb{R}^N$ we define the element $S_{\xi\eta}$ of the group algebra $\mathbb{C}W$ by

$$S_{\xi\eta} = (\xi, \eta) + \sum_{\alpha \in R_+} \frac{2g_\alpha(\alpha, \xi)(\alpha, \eta)}{(\alpha, \alpha)} s_\alpha.$$

This element comes from the commutation

$$[\nabla_\xi, (x, \eta)] = [\nabla_\eta, (x, \xi)] = S_{\xi\eta}.$$

Define the Dunkl angular momentum operator

$$M_{\xi\eta} = (x, \xi) \nabla_\eta - (x, \eta) \nabla_\xi.$$

Note that for any $w \in W$ and $\xi, \eta \in \mathbb{R}^N$ the following relations hold:

$$wM_{\xi\eta} = M_{w(\xi)w(\eta)}w,$$

$$M_{\xi\eta} = \sum_{i,j} \xi_i \eta_j M_{e_i e_j},$$

$$M_{\xi\eta} = -M_{\eta\xi}.$$

The Dunkl angular momenta algebra $H_{g}^{\text{sol}(N)}(W)$ is defined to be generated by the operators $M_{\xi\eta}$, and by the group algebra $\mathbb{C}W$. It can be considered as a subalgebra of the rational Cherednik algebra $H_g(W)$ via the homomorphism which maps $M_{e_i e_j} \rightarrow x_i D_j - x_j D_i$. 

20
Proposition 7. The Dunkl angular momenta satisfy

\[ [M_{\xi \eta}, M_{\varphi \psi}] = M_{\xi \psi} S_{\eta \varphi} + M_{\eta \varphi} S_{\xi \psi} - M_{\xi \varphi} S_{\eta \psi} - M_{\eta \psi} S_{\xi \varphi}, \]

(8.5)

\[ M_{\xi \eta} M_{\varphi \psi} + M_{\eta \varphi} M_{\xi \psi} + M_{\varphi \xi} M_{\eta \psi} = M_{\varphi \xi} S_{\eta \psi} + M_{\xi \eta} S_{\varphi \psi} + M_{\eta \varphi} S_{\xi \psi} \]

(8.6)

for any \( \xi, \eta, \varphi, \psi \in \mathbb{R}^N \).

The proposition can be checked straightforwardly by making use of the formulas

\[ [S_{\varphi \eta}, \nabla_{\psi}] = [S_{\psi \eta}, \nabla_{\varphi}], \quad [S_{\varphi \eta}, (x, \psi)] = [S_{\psi \eta}, (x, \varphi)]. \]

Similarly to Theorem 4 for \( W = S_N \), the algebra \( H^{so(N)}(W) \) can be defined as the quotient of the smash product algebra \( T(\Lambda^2 V) \# W \). Let the element \( M_{\xi \eta} \) correspond to \( (x, \xi) \otimes (x, \eta) - (x, \eta) \otimes (x, \xi) \in \Lambda^2 V \). Then the generating relations are given by (8.5), (8.6). The quotient has the basis given by monomials (4.10), (4.11) as in Theorem 4, where now \( \sigma \in W \). Thus \( H^{so(N)}(W) \) is a flat family of nonhomogeneous quadratic algebras over \( \mathbb{C}W \) of Poincaré–Birkhoff–Witt type.

Using the Dunkl operators (8.1), a generalisation of the \( H^{so(N)} \) invariant Hamiltonian (2.2) can be defined as follows:

\[ H = -\frac{1}{2} \sum_{i=1}^{N} \nabla_{\varepsilon_i}^2 = -\frac{1}{2} \sum_{i=1}^{N} \partial_{x_i}^2 + \sum_{\alpha \in \mathcal{R}_+} \frac{g_{\alpha}(g_{\alpha} - s_{\alpha})}{2(\alpha, x)^2}. \]

(8.7)

Similarly to the case \( W = S_N \) considered in Section II, let \( \text{Res} A \) be the restriction of a \( W \)-invariant element of the algebra \( H^{so(N)}(W) \) to the space of \( W \)-invariant functions \( \psi \):

\[ \psi(s_{\alpha} x) = \psi(x) \quad \forall \alpha \in \mathcal{R}. \]

Then the Calogero-Moser Hamiltonian for a general Coxeter group \( W \) is

\[ H_+ = \text{Res} H = -\frac{1}{2} \sum_{i=1}^{N} \partial_{x_i}^2 + \sum_{\alpha \in \mathcal{R}_+} \frac{g_{\alpha}(g_{\alpha} - 1)(\alpha, \alpha)}{2(\alpha, x)^2}. \]

(8.8)

In the Hamiltonians (8.7), (8.8), the radial and angular coordinates are separated giving rise to the relations (2.7) and (2.8). The angular Hamiltonians \( H_{\Omega} \) and \( H_{\Omega,+} \) can be expressed in terms of the Dunkl angular momentum operators (8.3).
Proposition 8. The angular Calogero–Moser Hamiltonians (2.7) and (2.8) can be obtained as

$$H_\Omega = -\frac{1}{2} (M^2 - S(S - N + 2)), \quad \text{(8.9)}$$

where we define the Dunkl angular momentum square and the symmetric group algebra invariant operators, respectively, as

$$M^2 = \sum_{i<j} M^2_{e_i e_j}, \quad S = -\sum_{\alpha \in \mathbb{R}_+} g_{\alpha} s_{\alpha}.$$

Generalisation of Theorem 5 holds for any $W$ and it has the following form.

Theorem 9. The centre $Z$ of the algebra $H^{g_0(N)}(W)$ is generated by the angular Hamiltonian (8.9) and constants.

The $gl(N)$ version of the algebra $H^{g_{gl(N)}}(W)$ can also be defined for any $W$ as the algebra generated by

$$E_{\eta \xi} = (x, \eta) \nabla_\xi$$

and $CW$, where $\xi, \eta \in V$ and the Dunkl operators are given by (8.1). It can also be thought as a subalgebra of the rational Cherednik algebra $H^g(W)$, which is isomorphic to the quotient of the smash product algebra $T(V \otimes V) \# CW$ over the relations (7.4), (7.6), where the elements $S_{ij} = S_{e_i e_j} \in CW$ are given by (8.2). The set of monomials (7.8), (7.9) with $\sigma \in W$ gives a basis of the algebra for any $W$-invariant multiplicity function $g$, and this is also a quadratic algebra over $CW$ of PBW type. The centre is generated by constants and

$$\rho = \sum_{i=1}^N E_{e_i e_i} + \sum_{\alpha \in \mathbb{R}_+} g_{\alpha} s_{\alpha}.$$

In the representation of the algebra $E_{\xi \eta} \rightarrow \bar{E}_{\xi \eta} = \frac{1}{2} ((x, \xi) - \nabla_\xi)((x, \eta) + \nabla_\eta)$ the central generator takes the form of the Calogero-Moser operator in the harmonic confinement associated with $W$:

$$\rho \rightarrow H + \frac{1}{2} x^2 - \frac{N}{2},$$

where $H$ is given by (8.7).
The considered algebras $H^{so(N)}_g(W)$, $H^{gl(N)}_g(W)$ have the form of the quotients of smash product algebras $T(U) \# \mathbb{C}W$, where $U = \Lambda^2 V$ or $U = V \otimes V$, and $V$ is the reflection representation of the Coxeter group $W$. In addition to the commutation relations the generators satisfy extra quadratic relations. These extra relations are needed in order to have algebras with the PBW property. It also means that we consider the semidirect products of the quotients of the corresponding universal enveloping algebras $U(so(N))$, $U(gl(N))$ and $W$ rather than the products of the universal enveloping algebras themselves.

Further, for the associated graded algebras the right-hand sides of the extra quadratic relations (8.6), (7.4) vanish. Thus we are dealing with Plücker relations and the affine cone $C$ over the grassmanian of two-planes in the $so(N)$ case and the space $\mathcal{M}$ of matrices of rank at most one in the $gl(N)$ case. It might be interesting to study the algebras $H^{so(N)}_g(W)$, $H^{gl(N)}_g(W)$ and their representations further, as well as their $t = 0$ versions in the notation of [8], in particular, in connection to (Poisson) geometry and singularities of the quotient of the spaces $C, \mathcal{M}$ over the natural action of the Coxeter group $W$. It would also be interesting to see whether there are algebras with good properties analogously associated to some other partial flag varieties or unions of coadjoint orbits.

A sheaf of algebras was associated to varieties with finite group actions in [24]. In the case of the projective space with the natural action of the Coxeter group $W$ the algebra of global sections is isomorphic to a quotient of the algebra $H^{gl(N)}_g(W)$ over the ideal generated by a central element [24] (see also [25]). Affinity of this sheaf of algebras was investigated in [25]. Another interesting question is about the extension of these results to the algebra $H^{so(N)}_g(W)$ and the sheaf of algebras associated with the subspace of isotropic lines in the projective space.

We also note that integrability of the angular Calogero–Moser systems deserves further analysis as, in particular, a complete set of Liouville charges remains unknown. The problem of Liouville integrability was one of the main motivations for this work and we hope that the work is a useful step towards its solution. There are a few reasons why the problem is difficult and remains unsolved which we try to explain (see also [11]). Firstly, in comparison with the case of the Calogero–Moser systems in the linear space, commutativity of homogeneous quantum integrals for the latter problem is quite straightforward and can be derived from
the property that the highest term of any quantum integral should be polynomial [26].

Secondly, one way to try to establish Liouville integrability for the angular Hamiltonian $H_\Omega$ is to consider the natural embedding of the universal enveloping algebras

$$U(so(2)) \subset U(so(3)) \subset \ldots \subset U(so(N)).$$

This chain immediately gives a complete set of commuting quantum integrals for the Laplace-Beltrami operator on the sphere which corresponds to $g = 0$ case. The corresponding operators are the realisations of the Casimir elements $M^2$. However, it is not clear how to extend this observation to $g \neq 0$ as the corresponding angular momentum operators $M_{ij}$ start depend on the parameter $n$ of the algebra $so(n)$ via the summation term of the Dunkl operator. So the algebras $H_g^{so(n)}(W)$ for different $n$ do not naturally embed one into another already for $W = S_n$.

Nonetheless, in the $gl(N)$ case a version of this construction exists at least for classical Coxeter groups $W$. In this case a correction $E'_{ii}$ of the operator $E_{ii}$ by group algebra elements is known so that $[E'_{ii}, E'_{jj}] = 0$ [27]. It would be interesting to try to extend this construction to other finite reflection groups $W$ and to try to modify Casimir elements $M^2$ to a commuting family. It is not plausible though that modification purely by group algebra elements is possible in the $so(N)$ case. A more general algebra at $g = 0$ one can alternatively start with is the quantum shift of argument algebra (see [28]) in which case one allows operators of order higher than 2.

In the case of $gl(N)$ and classical Coxeter groups $W$ it follows from [6] (for $W = A_{N-1}$) and [29] (for $W = B_N, D_N$) that the algebra $H_g^{gl(N)}(W)$ contains a complete set of Liouville quantum integrals for the Calogero–Moser Hamiltonian in harmonic confinement. Indeed, it is shown that a complete set of commuting quantum integrals is expressed via the combinations $a_i^+ a_i$. This suggests that the symmetry algebra $H_g^{so(N)}(W)$ might also be the right one for the angular Calogero–Moser Hamiltonian. We also note that the algebra and the above description of its centre has been recently explored in the study of Calogero–Moser deformation of the Coulomb problem and, in particular, for the construction of the generalisation of the Runge–Lenz vector [30].
ACKNOWLEDGMENTS

The authors are grateful to G. Bellamy, V. Dotsenko, P. Etingof, E. Feigin, D. Karakhanyan, H. Khudaverdian, O. Lechtenfeld and A. Nersessian for stimulating discussions and useful comments. The work was partially supported by the Royal Society/RFBR joint project JP101196/11-01-92612, and by the VolkswagenStiftung under Contract no. 86 260. T.H. is supported also by the Armenian State Committee of Science grant no. 15RF-039, as well as by ANSEF grant no. 3501.
