Generators of groups of Hamiltonian maps

Pierre Berger∗and Dmitry Turaev

October 27, 2022

Abstract

We prove that analytic Hamiltonian dynamics on tori, annuli, or Euclidean space can be approximated by a composition of nonlinear shear maps where each of the shears depends only on the position or only on the momentum.

1 Statement of the result.

Let $T^n := \mathbb{R}^n / \mathbb{Z}^n$ denote the $n$-torus. We endow the $2n$ torus $V := T^n \times T^n$ with the canonical coordinates $(q, p) = (q_1, \ldots, q_n, p_1, \ldots, p_n)$ and symplectic form $\omega = \sum_i dp_i \wedge dq_i$. For a function $H \in C^\infty(V, \mathbb{R})$, the system of differential equations defined by the Hamiltonian $H$ is given by

\begin{equation}
\dot{q} = \partial_p H, \quad \dot{p} = -\partial_q H.
\end{equation}

The corresponding vector field

$$X_H := (\partial_{p_1} H, \ldots, \partial_{p_n} H, -\partial_{q_1} H, \ldots, -\partial_{q_n} H),$$

satisfies $\omega(X_H, \cdot) = dH$; it is called the symplectic gradient of $H$. The symplectic gradient defines the Hamiltonian flow denoted by $\phi_H^t$, the family of time-$t$ maps along the trajectories of system (1.1). Similarly, given a continuous family of functions $H_t \in C^\infty(V, \mathbb{R})$, $t \geq 0$, one defines the time-dependent Hamiltonian system

\begin{equation}
(\dot{q}, \dot{p}) = X_{H,t} = (\partial_{p_t} H_t, -\partial_{q_t} H_t).
\end{equation}

The trajectories of this system define the family of maps $\phi_{H,t}^{s,t}$, $0 \leq s \leq t$: the solution with the initial condition $(q, p)$ at time $s$ arrives at the point $\phi_{H,t}^{s,t}(q, p)$ at time $t$. Such maps preserve the symplectic form $\omega$. The family of these maps is called the non-autonomous Hamiltonian flow of $H := (H_t)_{t \geq 0}$.

A symplectic map is called a Hamiltonian map if it is the map $\phi_{H,1}^0$ for a time-dependent Hamiltonian $H$. We consider the spaces $\text{Ham}^\infty(V)$ of Hamiltonian $C^\infty$-diffeomorphisms and $\text{Ham}^{*\omega}(V)$ of diffeomorphisms defined by real-analytic Hamiltonians $H_t$ which depend on $t$ continuously in $C^\omega(V, \mathbb{R})$.

Recall that the base of the $C^\omega$-topology (the inductive limit topology) on space of real-analytic functions is a collection, taken over all neighborhoods of $V = \mathbb{R}^{2n} / \mathbb{Z}^{2n}$ in its complexification $\mathbb{C}^{2n} / \mathbb{Z}^{2n}$, of $C^0$-open sets of holomorphic functions on such neighborhoods. Thus, a sequence of real-analytic functions $\phi_j$ converges to a real-analytic function $\phi$ on $V$ in $C^\omega$ iff there exists a

*IMJ-PRG, CNRS, Sorbonne University, Paris University, partially supported by the ERC project 818737 Emergence of wild differentiable dynamical systems.
neighborhood $V_\rho$ of $V$ in the complexification $\mathbb{C}^{2n}/\mathbb{Z}^{2n}$ where $\phi$ and every $\phi_j$ for $j$ large enough have their analytic extensions well defined and $\sup_{V_\rho} \|\phi_j - \phi\| \to 0$ as $j \to +\infty$. The space $\text{Ham}^\omega(V)$ is formed by analytic mappings; it is considered with the inductive limit topology as described above.

Both $\text{Ham}^\infty(V)$ and $\text{Ham}^\omega(V)$ are groups (this follows from the identity $\phi^0_0 \circ \phi^0_H = \phi^0_K$, where $K_t = G_t + H_t \circ (\phi^0_H)^{-1}$).

The simplest examples of Hamiltonian maps are given by \textit{vertical} and \textit{horizontal} shear maps:

- a horizontal shear $(q, p) \mapsto (q + \nabla \tau(p), p)$ is the time-1 map for the time-independent Hamiltonian $H(q, p) = \tau(p)$, where $\tau \in C^\omega(\mathbb{T}^n, \mathbb{R})$;
- a vertical shear $(q, p) \mapsto (q, p - \nabla v(q))$ is the time-1 map for the time-independent Hamiltonian $H(q, p) = v(q)$, where $v \in C^\omega(\mathbb{T}^n, \mathbb{R})$.

The system of differential equations defined by Hamiltonian $H(q, p) = \tau(p)$ is

$$\dot{q} = \nabla \tau(p), \quad \dot{p} = 0;$$

its flow map $\phi^t_H : (q, p) \mapsto (q + t\nabla \tau(p), p)$ is a horizontal shear for every $t \in \mathbb{R}$. Similarly, the flow map $\phi^t_H : (q, p) \mapsto (q, p - t\nabla v(q))$ for $H(q, p) = v(q)$ is a vertical shear for every $t \in \mathbb{R}$. We see that the vertical and horizontal shear maps form Abelian subgroups of $\text{Ham}^\omega(V)$, which we denote as $V$ and, respectively, $T$.

\textbf{Theorem. (Main)} The group $< V, T >$ generated by $V$ and $T$ is dense in $\text{Ham}^\omega(V)$. In other words, every real-analytic Hamiltonian diffeomorphism of $V$ can be $C^\omega$-approximated by a composition $S_M \circ \ldots \circ S_1$ where $S_j \in T \cup V$, $j = 1, \ldots, M$.

The proof is given in the next Section. Since $\text{Ham}^\omega(V)$ is $C^\infty$-dense in $\text{Ham}^\infty(V)$, we obtain

\textbf{Corollary 1.1.} The group generated by $V$ and $T$ is dense in $\text{Ham}^\infty(V)$.

Note that any real-analytic function on $\mathbb{R}^n$ can be arbitrarily well approximated, on any given compact, by a periodic function with a sufficiently large period. Therefore, the lifts of Hamiltonian maps of $\mathbb{T}^n \times \mathbb{T}^n$ approximate (on any given compact) Hamiltonian maps of an annulus $\mathbb{T}^n \times \mathbb{R}^n$ or a ball $\mathbb{R}^n \times \mathbb{R}^n$. This implies

\textbf{Corollary 1.2.} The theorem extends to the cases where $V = \mathbb{T}^n \times \mathbb{R}^n$ and $V = \mathbb{R}^n \times \mathbb{R}^n$: every Hamiltonian map is approximated by a composition of vertical and horizontal shears.

Along the proof of the main theorem, we will check that the “parametric version” of the results also holds. Namely, we have the following

\textbf{Corollary 1.3.} Given a compact real-analytic manifold $\mathcal{P}$, every analytic family $f_\mathcal{P} = (f_{\mu})_{\mu \in \mathcal{P}}$ of Hamiltonian diffeomorphisms of $\mathbb{T}^n \times \mathbb{T}^n$, $\mathbb{T}^n \times \mathbb{R}^n$ or $\mathbb{R}^n \times \mathbb{R}^n$ can be arbitrarily well approximated by analytic families of compositions of vertical and horizontal shears. For any compact set $\mathcal{P}$, every continuous family $f_\mathcal{P} = (f_{\mu})_{\mu \in \mathcal{P}}$ of analytic Hamiltonian diffeomorphisms of $\mathbb{T}^n \times \mathbb{T}^n$, $\mathbb{T}^n \times \mathbb{R}^n$ or $\mathbb{R}^n \times \mathbb{R}^n$ can be arbitrarily well approximated by continuous families of compositions of vertical and horizontal shears.

To be precise, we recall that a sequence of continuous families $(f_{j, \mu})_{\mu \in \mathcal{P}}$ of analytic diffeomorphisms on $V$ converges to $(f_{\mu})_{\mu \in \mathcal{P}}$ if there exists a complex neighborhood $V_\rho$ of $V$ such that for every $\delta > 0$, for every $j$ large enough, $\sup_{(\mu, x) \in \mathcal{P} \times V_\rho} \|f_{\mu}(x) - f_{j, \mu}(x)\| < \delta$. Also, we call a family $(f_{j, \mu})_{\mu \in \mathcal{P}}$ analytic if $f_{\mu}(x)$ is a real-analytic function of $\mu$ and $x$; the convergence in Corollary 1.3 is then in $C^\omega(\mathcal{P} \times V, V)$. These two settings (of continuous and analytic families) seem to be most
natural. In order to consider them in a unified way, we adopt from now on a more general setting where \( \mathcal{P} \) denotes always a product:

\[
\mathcal{P} = \mathcal{P}_1 \times \mathcal{P}_2
\]

of a compact set \( \mathcal{P}_1 \) and a compact analytic manifold \( \mathcal{P}_2 \). Also from now on, the considered family \( f_\mathcal{P} = (f_\mu)_{\mu \in \mathcal{P} = \mathcal{P}_1 \times \mathcal{P}_2} \) will be analytic in \( \mu_2 \) and continuous with respect to \( \mu_1 \). Each map \( f_\mu(x) \) is the time-1 map of a time-dependent Hamiltonian \( H_{\mu,t}(x) \); we assume that \( H \) is an analytic function of \( (\mu_2,x) \) and a continuous (in the topology of \( C^\omega(\mathcal{P}_2 \times V, \mathbb{R}) \)) function of \( (\mu_1,t) \), and say that the family \( f_\mathcal{P} \) is generated by the family \( (H_{\mu,t})_{\mu,t} \).

Remark 1.4. For the ease of presentation, the main theorem is given for \( \mathbb{T}^n \times \mathbb{T}^n \) endowed with the standard symplectic form \( \omega = \sum_i dp_i \wedge dq_i \), but the proof, with obvious modifications, works also for any symplectic form of the form \( \sum_i a_i dp_i \wedge dq_i \), with constant \( a_i > 0 \). A natural question is how to extend the results to other symplectic forms on the torus or to other product symplectic manifolds.

The main Theorem implies\( ^1 \) the work [Tur02] where symplectic maps of \( V = \mathbb{R}^{2n} \) were considered in the smooth case. While we found a way to extend the method of [Tur02] to the annulus case, we prefer to present here a more powerful approach, inspired by a technology developed in [BGH22, §2.4-3.2 and app. A] for the non-symplectic case. Similar results for holomorphic automorphisms of \( \mathbb{C}^n \), including the volume-preserving case, were obtained in [And90, AL92] and have played an important role in solving several problems of complex analysis, see review in [FK22]. The symplectic result of [Tur02] for \( V = \mathbb{R}^{2n} \) was key for the proof of the genericity of the “ultimately rich” (universal) dynamics for certain classes of symplectic and non-symplectic maps [GTS07, GT10, Tur15, GT17] and for the proof of Herman’s metric entropy conjecture [BT19]. It has also been used in algorithms for physics-informed machine learning [JZZ+20, BTM20, VWT+22]. The current result and its short constructive proof for the annulus \( V = \mathbb{T} \times \mathbb{R} \) enabled to disprove the Birkhoff conjecture in [Ber22].

2 Proof of the main theorem

We use the Poisson algebra structure on \( C^\omega(V, \mathbb{R}) \), which is the Hamiltonian counterpart of the Lie algebra structure on the space of vector fields on \( V \). Namely, given two functions \( f, g \in C^\omega(V, \mathbb{R}) \) the Poisson bracket \( \{f, g\} \) is the function defined by

\[
\{f, g\} = \sum_i \partial_{q_i} f \cdot \partial_{p_i} g - \partial_{q_i} g \cdot \partial_{p_i} f.
\]

It is easy to check that the Lie bracket of the Hamiltonian vector fields \( X_f \) and \( X_g \) is the Hamiltonian vector field \( X_{\{f,g\}} \).

Cartan’s Theorem establishes a correspondence between closed subgroups and Lie sub-algebras for finite-dimensional Lie groups. Certain aspects of this correspondence have been generalized in [BGH22, Prop. B.1] for the group of compactly supported smooth diffeomorphisms. Below is the counterpart for the group of analytic Hamiltonian diffeomorphisms:

**Proposition 2.1.** Let a set \( G \) be a closed subgroup of \( \text{Ham}^\omega(V) \). Let \( \mathcal{P}(G) \) be the set of all time-independent Hamiltonians \( H \in C^\omega(V, \mathbb{R}) \) such that their flow maps \( \phi_H^t \) belong to \( G \) for all \( t \in \mathbb{R} \):

\[
\mathcal{P}(G) := \{ H \in C^\omega(V, \mathbb{R}) : \phi_H^t \in G, \forall t \}.
\]

\( ^1 \)A shear map of \( \mathbb{R}^{2n} \) is the composition of two Hénon maps. So the main result implies that compositions of Hénon maps form a dense set in \( \text{Ham}^\omega(\mathbb{R}^{2n}) \).
Then \( P(G) \) is a closed Lie sub-algebra of \( C^\infty(V) \). In other words, it is a closed vector subspace of \( C^\infty(V) \) and the Poisson bracket of any two functions from \( P(G) \) also belongs to \( P(G) \).

**Proof.** First note that \( P(G) \) is closed by continuity of \( H \mapsto \phi_H^t \) for every \( t \in \mathbb{R} \). Then the proposition follows from the two lemmas below.

**Lemma 2.2.** The set \( P(G) \) is a vector space.

**Lemma 2.3.** The vector space \( P(G) \) is a Lie algebra.

**Proof of Lemma 2.2.** Let \( H \in P(G) \) and \( \lambda \in \mathbb{R} \). For every \( t \in \mathbb{R} \), the map \( \phi_H^\lambda \) belongs to \( G \) and so \( \lambda H \in P(G) \). Hence, it suffices to show that \( H_1 + H_2 \in P(G) \), for every \( H_1, H_2 \in P(G) \). As \( \phi_{H_1+H_2}^t = \phi_{H_1}^t \circ \phi_{H_2}^t \), and \( tH_1, tH_2 \in P(G) \) whenever \( H_1, H_2 \in P(G) \) as we just showed, it suffices to check that \( \phi_{H_1+H_2}^t \in G \) for every \( H_1, H_2 \in P(G) \).

On a complex extension \( V_0 \) of \( V \), the following holds uniformly as \( t \to 0 \):

\[
\phi_{H_1}^t \circ \phi_{H_2}^t = id + t \cdot \partial_t (\phi_{H_1}^t \circ \phi_{H_2}^t)_{t=0} + O(t^2) = id + t \cdot (X_{H_1} + X_{H_2}) + O(t^2)
\]

\[
= id + t \cdot \partial_t (\phi_{H_1}^t \circ \phi_{H_2}^t)_{t=0} + O(t^2) = \phi_{H_1+H_2}^t.
\]

In particular, there exists \( C > 0 \) such that for every \( N \geq 1 \)

\[
(2.1) \quad \sup_{V_0} \| \phi_{H_1+H_2}^{1/N} - (\phi_{H_1}^{1/N} \circ \phi_{H_2}^{1/N})^{N} \| \leq C \cdot N^{-2}.
\]

Taking sufficiently small complex neighborhoods \( V_2 \subset V_1 \subset V_0 \) of \( V \) and applying Discretization Lemma 3.1, we infer from (2.1) that

\[
\sup_{V_2} \| \phi_{H_1+H_2}^{1/N} - (\phi_{H_1}^{1/N} \circ \phi_{H_2}^{1/N})^{N} \| \leq C \exp(L)N^{-1} \quad \forall N \geq N_0
\]

for some constants \( L \) and \( N_0 \) (in the Discretization Lemma, put \( c_N := C/N \), \( \phi^{\pm t} := \phi_{H_1+H_2}^{t \pm s} \), and \( g_s = \phi_{H_1}^{1/N} \circ \phi_{H_2}^{1/N} \) for all \( j \)).

Thus \( \phi_{H_1+H_2}^{1} \) is arbitrarily close to the element \( (\phi_{H_1}^{1/N} \circ \phi_{H_2}^{1/N})^{N} \) of the group \( G \). As \( G \) is closed, it follows that \( \phi_{H_1+H_2}^{1} \in G \), as required.

**Proof of Lemma 2.3.** It suffices to show that for any \( H_1, H_2 \in P(G) \), the function \( H_3 = \{ H_1, H_2 \} \) belongs to \( P(G) \). Since \( \phi_{H_3}^t = \phi_{tH_1+H_2}^t \) and \( tH_1 \in P(G) \) whenever \( H_1 \in P(G) \), we only need to show that \( \phi_{H_3}^t \) belongs to \( G \). On a complex extension \( V_0 \) of \( V \), we have, uniformly as \( t \to 0 \):

\[
(2.2) \quad \phi_{H_j}^t = id + tX_{H_j} + \frac{t^2}{2} DX_{H_j} \cdot X_{H_j} + O(t^3), \quad j = 1, 2, 3.
\]

So,

\[
\phi_{H_1}^{t/N} \circ \phi_{H_2}^{t/N} = id + \frac{t}{N}(X_{H_1} + X_{H_2}) + \frac{t^2}{2N^2}(DX_{H_1} \cdot X_{H_1} + DX_{H_2} \cdot X_{H_2} + 2DX_{H_1} \cdot X_{H_2}) + O(t^3)
\]

\[
\phi_{H_1}^{-t/N} \circ \phi_{H_2}^{-t/N} = id - \frac{t}{N}(X_{H_1} + X_{H_2}) + \frac{t^2}{2N^2}(DX_{H_1} \cdot X_{H_1} - DX_{H_2} \cdot X_{H_2} + 2DX_{H_2} \cdot X_{H_1}) + O(t^3).
\]

Thus, uniformly on \( V_0 \) as \( t \to 0 \),

\[
(2.3) \quad \phi_{H_1}^{-t} \circ \phi_{H_2}^{-t} \circ \phi_{H_1}^{t} \circ \phi_{H_2}^{t} = id + t^2(DX_{H_1} \cdot X_{H_2} - DX_{H_2} \cdot X_{H_1}) + O(t^3).
\]
One can check that $DX_{H_1}(X_{H_2}) - DX_{H_2}(X_{H_1})$ is the symplectic gradient of $H_3 = \{H_1, H_2\}$. Thus Eq. (2.2) at $j = 3$ and Eq. (2.3) imply the existence of $C > 0$ such that for $N \equiv t^{-2}$ sufficiently large,

\begin{equation}
(2.4) \quad \sup_{V_0} \left\| \phi_{H_3}^{1/N} - \phi_{H_1}^{-1/\sqrt{N}} \circ \phi_{H_2}^{-1/\sqrt{N}} \circ \phi_{H_1}^{1/\sqrt{N}} \circ \phi_{H_2}^{1/\sqrt{N}} \right\| \leq C \frac{1}{N^{3/2}}.
\end{equation}

From this, taking sufficiently small complex neighborhoods $V_2 \Subset V_1 \subset V_0$, one finds that the assumptions of the Discretization Lemma 3.1 are satisfied with $\varepsilon_N := C/\sqrt{N}$, $\phi^{s,t} := \phi^{1-s}_{H_3}$, and $g_j = \phi_{H_1}^{-1/\sqrt{N}} \circ \phi_{H_2}^{-1/\sqrt{N}} \circ \phi_{H_1}^{1/\sqrt{N}} \circ \phi_{H_2}^{1/\sqrt{N}}$ for all $j$. This implies that for some $L$ and $N_0$

$$
\sup_{V_2} \left\| \phi_{H_3}^{1} - (\phi_{H_1}^{-1/\sqrt{N}} \circ \phi_{H_2}^{-1/\sqrt{N}} \circ \phi_{H_1}^{1/\sqrt{N}} \circ \phi_{H_2}^{1/\sqrt{N}})^N \right\| \leq C \exp(L)N^{-1/2}, \quad \forall N \geq N_0.
$$

Thus $\phi_{H_3}^{1}$ is arbitrarily close to the element $(\phi_{H_1}^{-1/\sqrt{N}} \circ \phi_{H_2}^{-1/\sqrt{N}} \circ \phi_{H_1}^{1/\sqrt{N}} \circ \phi_{H_2}^{1/\sqrt{N}})^N$ of the group $G$. As $G$ is closed, it follows that $\phi_{H_3}^{1} \in G$, as required. \hfill \Box

The space of families of analytic Hamiltonian maps endowed with the composition rule $(f_\mu)_{\mu \in \mathcal{P}} \circ (g_\mu)_{\mu \in \mathcal{P}} = (f_\mu \circ g_\mu)_{\mu \in \mathcal{P}}$ is a group. One can check that the proof of the above proposition does not alter as long as $\mathcal{P}$ is compact, by using the parametric counterpart Corollary 3.2 of Lemma 3.1. Namely, we have

**Corollary 2.4.** If $G_\mathcal{P}$ is a closed subgroup of the space of families of analytic Hamiltonian maps then the following is a closed sub-algebra of the space of families of functions on $\mathcal{V}$:

$$
\mathcal{P}(G_\mathcal{P}) := \{(H_{\mu})_{\mu \in \mathcal{P}} : (\phi_{H_{\mu}}^1)_{\mu \in \mathcal{P}} \in G_\mathcal{P}, \forall t\}.
$$

We apply Proposition 2.1 to the group $G$ obtained by taking the $C^\omega$-closure of the group $< \mathcal{V}, \mathcal{T} >$ generated by $\mathcal{V}$ and $\mathcal{T}$:

$$
G = cl(< \mathcal{V}, \mathcal{T} >).
$$

Recall that the groups $\mathcal{V}$ and $\mathcal{T}$ of vertical and horizontal shears consist of the time-1 maps for the time-independent Hamiltonian functions which depend only on $p$ or, respectively, only on $q$. For such functions, the time-$t$ map belongs to $\mathcal{V}$ or, respectively, $\mathcal{T}$ for all $t \in \mathbb{R}$. Thus, the $C^\omega$ Hamiltonians of the form $H(q,p) = \tau(p)$ or $H(q,p) = v(q)$ belong to the Lie algebra $\mathcal{P}(G)$. This implies, by Proposition 2.1, that every Hamiltonian of the form

\begin{equation}
(2.5) \quad H(q,p) = v_0(q) + \sum_{1 \leq r \leq R} \{w_r(q), \{v_r(q), \tau_r(p)\}\}
\end{equation}

lies in $\mathcal{P}(G)$; here $R \geq 0$ and $\tau_r, v_r, w_r \in C^\omega(\mathbb{T}^n, \mathbb{R})$.

We denote the set comprised by $C^\omega$-functions $\mathbb{T}^n \times \mathbb{T}^n \to \mathbb{R}$ which can be represented in the form (2.5) as $\hat{\mathcal{P}}$. In short one can denote:

$$
\hat{\mathcal{P}} = \mathcal{V} + \{\mathcal{V}, \{\mathcal{V}, \mathcal{T}\}\}.
$$

As we said, $\hat{\mathcal{P}} \subset \mathcal{P}(G)$, i.e., for every $H \in \hat{\mathcal{P}}$ its flow maps $\phi_H^t$ can be arbitrarily well approximated by compositions of vertical and horizontal shears.

**Proposition 2.5.** The set $\hat{\mathcal{P}}$ is dense in $C^\omega(V, \mathbb{R})$. 

\vfill

5
Proof. By Fourier’s Theorem, any $C^\omega$ function on the torus $V$ can be approximated by a trigonometric polynomial, i.e., a function of the form

$$\sum_{\max_j \{ |m_j|, |k_j| \} \leq K} \text{Re}(e^{2\pi i (m,q) + \langle k,p \rangle}),$$

where $m$ and $k$ are integer-valued $n$-vectors, and $\langle \cdot , \cdot \rangle$ denotes the inner product. Therefore, it is enough to show that every trigonometric polynomial belongs to $\mathcal{P}$, i.e., it has the form (2.5) for some choice of the functions $v$, $w$, and $\tau$. Thus, we choose $v_0(q) = \sum_{\max_j |m_j| \leq K} \text{Re}(e^{2\pi i (m,q) + \langle k,p \rangle})$, and it remains to show that for every $k$ and $m$ such that $k \neq 0$ the term $\text{Re}(e^{2\pi i (m,q) + \langle k,p \rangle})$ is a linear combination of terms which can be represented as \{w_\tau(q), \{v_\tau(q), \tau(p)\}\}.

This is done as follows. Since $k \neq 0$, there exists an index $j$ such that $k_j \neq 0$. Hence there is $\sigma \in \{-1,1\}$ such that $A = (\sum_{s=1}^n m_sk_s) - \sigma k_j$ is not zero.

We denote $m' = (m_1',\ldots,m_n')$, where $m_j' = m_j - \sigma$ and $m_s' = m_s$ if $s \neq j$. Then

$$e^{2\pi i (m,q) + \langle k,p \rangle} = e^{2\pi i m'q} e^{2\pi i k p} e^{2\pi i \sigma q j},$$

so $\text{Re}(e^{2\pi i (m,q) + \langle k,p \rangle})$ is a linear combination of products of cosines or sines of $2\pi < m', q >$, $2\pi < k, p >$, and $2\pi \sigma q_j$. Hence, it suffices to show that for every $(\alpha, \beta, \gamma)$ there exist functions $w$, $v$, and $\tau$ such that

$$(2.6) \quad \sin(2\pi < m', q > + \alpha) \sin(2\pi < k, p > + \beta) \sin(2\pi \sigma q_j + \gamma) = \{w(q), \{v(q), \tau(p)\}\}.$$  

For that, we choose

$$v(q) = \frac{\cos(2\pi < m', q > + \alpha)}{2\pi A}, \quad \tau(p) = -\frac{\sin(2\pi < k, p > + \beta)}{2\pi}, \quad w(q) = \frac{\cos(2\pi \sigma q_j + \gamma)}{4\pi^2 k_j \sigma}.$$  

Now, we have:

$$\{v(q), \tau(p)\} = \langle \nabla_q v, \nabla_p \tau \rangle = \sum_{s=1}^n m'_s k_s A \sin(2\pi < m', q > + \alpha) \cos(2\pi < k, p > + \beta)$$

and as $A = \sum_{s=1}^n m'_s k_s$,

$$\{v(q), \tau(p)\} = \sin(2\pi < m', q > + \alpha) \cos(2\pi < k, p > + \beta).$$

As $w$ is a function of only one variable, $q_j$, we have:

$$\{w(q), \{v(q), \tau(p)\}\} = w'(q_j) \partial_{q_j} \{v(q), \tau(p)\},$$

which gives Eq. (2.6) since $\partial_{q_j} \{v(q), \tau(p)\} = -2\pi \cdot k_j \cdot \sin(2\pi < m', q > + \alpha) \sin(2\pi < k, p > + \beta)$ and $w'(q_j) = -\frac{\sin(2\pi \sigma q_j + \gamma)}{2\pi k_j}$.  

Proposition 2.5 implies that the flow maps $\phi^t_H$ of any time-independent Hamiltonian $H \in C^\omega(V, \mathbb{R})$ can be arbitrarily well approximated by the flow maps of some Hamiltonians from $\mathcal{P}$. Since $\mathcal{P} \subset \mathcal{P}(G)$ and $\mathcal{P}(G)$ is closed subset of $C^\omega(V, \mathbb{R})$, this gives $\mathcal{P}(G) = C^\omega(V, \mathbb{R})$ and so:

**Proposition 2.6.** For every time-independent Hamiltonian $H$ its time-$t$ maps can, for every $t$, be arbitrarily well approximated by compositions of vertical and horizontal shears.
Using Corollary 2.4 and the fact that the approximation given by the proof of Proposition 2.5 is based on the Fourier’s decomposition which depends analytically on the function considered, we obtain

**Corollary 2.7.** Every family of time-independent Hamiltonian functions \((H_\mu)_{\mu \in \mathcal{P}}\), the family of its time-\(t\) maps can, for every \(t\), be arbitrarily well approximated by families of compositions of vertical and horizontal shears.

To finish the proof of the theorem, we now show that the same is true for time-dependent Hamiltonians. First, we prove

**Lemma 2.8.** Every diffeomorphism \(f \in \text{Ham}^\omega(V)\) can be approximated by a composition of flow maps defined by time-independent Hamiltonians. More precisely, if \(f\) is the flow map \(\phi_H^{0,1}\) of a time-dependent Hamiltonian \(H = (H_t)_{t \geq 0}\), then there is a complex neighborhood \(W\) of \(V\) such that for every \(\eta > 0\), the holomorphic extension \(f|_W\) is \(\eta\)-close, for all sufficiently large \(N\), to the composition of time-\(1/N\) maps \(\phi_H^{1/N}\) for the time-independent Hamiltonians \(H_{j/N}^\prime\):

\[
\sup_W \left\| f - \phi_H^{1/N} \circ \cdots \circ \phi_H^{1/N} \circ \phi_H^{1/N} \right\| < \eta.
\]

**Proof.** We have:

\[
f = \phi_H^{0,1} = \phi_H^{(N-1)/N,1} \circ \phi_H^{(N-2)/N,(N-1)/N} \circ \cdots \circ \phi_H^{1/N,2/N} \circ \phi_H^{0,1/N}.
\]

Using the compactness of the time interval \([0, 1]\), there exists a complex neighborhood \(V_0\) of \(V\) and a sequence \(\varepsilon_N \to 0\) such that the flow maps for time-independent Hamiltonians satisfy

\[
\sup_{V_0} \left\| \phi_H^{1/N} - id - \frac{1}{N} X_{Ht} \right\| \leq \frac{\varepsilon_N}{2N}, \quad \forall 0 \leq t \leq 1, \forall N \geq 1,
\]

and the non-autonomous flow maps satisfy

\[
\sup_{V_0} \left\| \phi_H^{t,t+1/N} - id - \frac{1}{N} X_{Ht,t} \right\| = \sup_{V_0} \left\| \int_t^{t+1/N} X_{Hs,s} \circ \phi_H^{t,s} ds - \frac{1}{N} X_{H,t} \right\| \leq \frac{\varepsilon_N}{2N}, \quad \forall 0 \leq t \leq 1 - 1/N.
\]

By Eq. (1.2), the vector fields \(X_{H,t}\) and \(X_{H,t}\) are equal. Thus, summing these two estimates taken at \(t = j/N\), we obtain:

\[
\sup_{V_0} \left\| \phi_H^{j/N,(j+1)/N} - \phi_H^{1/N}_{j/N} \right\| \leq \frac{\varepsilon_N}{N}, \quad \forall 0 \leq j \leq 1 - 1/N.
\]

From this, it easy to find complex neighborhoods \(W = V_2 \subset V_1 \subset V_0\) which satisfy the assumptions of Lemma 3.1 with \(\phi^{s,t} := \phi_H^{s,t}\) and \(g_j := \phi_H^{1/N}_{j/N}\). This implies the sought bound: there exists \(L > 0\) such that for all \(N\) large enough

\[
\sup_{V_2} \left\| \phi_H^{0,1} - g_{N-1} \circ \cdots \circ g_0 \right\| \leq \exp(L) \cdot \varepsilon_N.
\]

\(\square\)

If, in the above proof, we consider parametric families and employ Corollary 3.3 instead of Lemma 3.1, we obtain
Corollary 2.9. Every family of analytic Hamiltonian diffeomorphisms \((f_{\mu})_{\mu \in \mathcal{P}}\) can be approximated by compositions of families of flow maps defined by time-independent Hamiltonians taken from the family of Hamiltonians that generates \((f_{\mu})_{\mu \in \mathcal{P}}\).

Now, let \(f\) be the time-1 map for a time-dependent Hamiltonian \((H_t)_{0 \leq t \leq 1}\). For every frozen value of \(s \in [0, 1]\), consider the function \(H_s : V \to \mathbb{R}\) as a time-independent Hamiltonian and take its time-\(t\) flow map. This defines a family of maps

\[
(\phi_{t}^{s})_{0 \leq s, t \leq 1}.
\]

It is a continuous 2-parameter family of time-independent Hamiltonian flow maps; hence by Corollary 2.7, there exists a complex neighborhood \(W_0\) of \(V\) such that for every \(\eta > 0\) there is a continuous family \((g_{s})_{0 \leq s \leq 1}\) of compositions of vertical and horizontal shears, such that:

\[
\sup_{W_0} \|\phi_{t}^{s} - g_{s}\| \leq \eta, \quad \forall 0 \leq s, t \leq 1.
\]

Thus, for any complex neighborhood \(W_1 \subseteq W_0\), if \(\eta\) is small enough, then the differences

\[
(\phi^{1/N}_{H(N_{j-1})/N} \circ \cdots \circ \phi^{1/N}_{H_{j/N}} - \phi^{1/N}_{H(N_{j-1})/N} \circ \cdots \circ \phi^{1/N}_{H_{j/N}} \circ g^{1/N}_{0} \circ \cdots \circ g^{1/N}_{0})
\]

are uniformly small (for all \(N\) and all \(j = 1, \ldots, N - 1\)) on \(W_1\).

Summing this over \(1 \leq j \leq N - 1\), we obtain that \(\phi^{1/N}_{H(N_{j-1})/N} \circ \cdots \circ \phi^{1/N}_{H_{j/N}} \circ \phi_{H_{0}}^{1/N} \circ g_{(N_{j})/N}^{1/N} \circ \cdots \circ g_{0}^{1/N}\) are uniformly close on \(W_1\). Now, we invoke Lemma 2.8, which gives the existence of a complex neighborhood \(W_2 \subset W_1\) such that for every \(\delta > 0\), if \(N\) is sufficiently large, then \(f\) is \(\delta/2\)-close to \(\phi^{1/N}_{H(N_{j-1})/N} \circ \cdots \circ \phi^{1/N}_{H_{j/N}} \circ \phi_{H_{0}}^{1/N}\) on \(W_2\). Thus, for \(N\) large enough, we have

\[
\sup_{W_2} \|f - g_{(N_{j})/N}^{1/N} \circ \cdots \circ g_{0}^{1/N}\| \leq \delta.
\]

Since \(W_2\) does not depend on \(\delta\), it follows that \(\phi_{H}^{1/N}\) can be approximated arbitrarily well by a composition of vertical and horizontal shears. This proves the theorem. Corollary 1.3 is proved exactly in the same way, just the family \((\phi_{t}^{s})\) now also depends on the additional parameters \(\mu \in \mathcal{P}\) and, instead of Lemma 2.8 we employ its pragmatic version Corollary 2.7.

3 Bounds on compositions

The following lemma was used several times in the proof above. It works actually on any analytic manifold and the dynamics does not need to be Hamiltonian nor real. Let \(V_0\) be a complex manifold and \(V_1\) a neighborhood of a compact subset \(V_2\) of \(V_0\): \(V_2 \subseteq V_1 \subset V_0\).

Lemma 3.1. (Discretization lemma) For any \(L > 0\) and any positive sequence \(\varepsilon_N \to 0\), there is \(N_0\) such that the following property holds true for every \(N \geq N_0\).

(i) Let \(X := (X_t)_{t \in [0,1]}\) be any time-dependent vector field, holomorphic on \(V_0\) and continuously dependent on time, such that its flow \((\phi^{s,t})_{0 \leq s \leq t \leq 1}\) is defined on \(V_1\) and its derivative is bounded by \(L\):

\[
V_1^t := \phi^{0,t}(V_1) \subset V_0 \quad \text{and} \quad \sup_{x \in V_1^t} \|\partial_x X_t\| \leq L \quad \forall t \in [0,1].
\]
(ii) Let any sequence of analytic maps $g_j, 0 \leq j \leq N - 1$, be defined on $V_1^{j/N}$ and satisfying
\begin{equation}
\sup_{V_1^{j/N}} \left\| \phi^{j/N,(j+1)/N} - g_j \right\| < \frac{\varepsilon N}{N}, \quad \forall 0 \leq j < N.
\end{equation}

Then the composition $g_{N-1} \circ \ldots \circ g_0$ is well-defined on $V_2$ and satisfies
\begin{equation}
\sup_{V_2} \left\| \phi^{0,1} - g_{N-1} \circ \ldots \circ g_0 \right\| < \exp(L) \cdot \varepsilon N.
\end{equation}

Proof. We show, by induction in $k$, that for every $k = 1, \ldots, N$ the composition $g_{k-1} \circ \ldots \circ g_0$ is well-defined on $V_2$ and satisfies
\begin{equation}
\sup_{V_2} \left\| \phi^{0,k/N} - g_{k-1} \circ \ldots \circ g_0 \right\| < \frac{1 + \ldots + \exp(kL/N)}{N} \cdot \varepsilon N
\end{equation}
for all $N \geq N_0$. Obviously, this gives (3.2) at $k = N$.

Note that by Grönwall’s inequality
\begin{equation}
\sup_{x \in V_1^t} \| \partial_x \phi^{s,t} \| \leq \exp(L(t-s)), \quad 0 \leq s \leq t \leq 1.
\end{equation}

In particular, the maps $\phi^{s,t}$ are uniformly continuous, hence there is $\eta > 0$ (depending only on $L$) such that $V_1^t$ contains the $\eta$-neighborhood of $V_2^t := \phi^{0,t}(V_2)$ for every $0 \leq t \leq 1$.

Now, assume (3.3) is true for some $k \leq N$ (it is true at $k = 1$ by assumption). This implies
\begin{equation*}
\sup_{V_2} \left\| \phi^{0,k/N} - g_{k-1} \circ \ldots \circ g_0 \right\| < \exp(L)\varepsilon N,
\end{equation*}
hence for all sufficiently large $N$:
\begin{equation*}
\sup_{V_2} \left\| \phi^{0,k/N} - g_{k-1} \circ \ldots \circ g_0 \right\| < \eta.
\end{equation*}

Therefore, the image $g_{k-1} \circ \ldots \circ g_0(V_2)$ lies in the $\eta$-neighborhood of $V_2^{k/N}$. This is a subset of $V_1^{k/N}$ where $g_k$ is defined by assumption, so the composition $g_k \circ \ldots \circ g_0$ is well-defined on $V_2$, as required. Since
\begin{equation*}
\phi^{0,(k+1)/N} = \phi^{k/N,(k+1)/N} \circ \phi^{0,k/N},
\end{equation*}
it follows from (3.4) and (3.3) that
\begin{equation*}
\sup_{V_2} \left\| \phi^{0,(k+1)/N} - \phi^{k/N,(k+1)/N} \circ g_{k-1} \circ \ldots \circ g_0 \right\| < \exp(L/N) \frac{1 + \ldots + \exp(kL/N)}{N} \cdot \varepsilon N.
\end{equation*}

By (3.1) at $j = k$, we have
\begin{equation*}
\sup_{V_2} \left\| \phi^{k/N,(k+1)/N} - g_k \circ g_{k-1} \circ \ldots \circ g_0 \right\| < \frac{1}{N} \cdot \varepsilon N.
\end{equation*}

Summing up these two inequalities, we obtain inequality (Eq. (3.3)) at $k + 1$, i.e., we complete the induction step.

Let us emphasis that the bound on the above lemma depends only on $L$ and $V_2 \subseteq V_1 \subseteq V_0$. So it implies immediately the following for family parametrized by a set $E$ (not necessarily topological).
Corollary 3.2. For any $L > 0$ and any positive sequence $\varepsilon_N \to 0$, there is $N_0$ such that the following property holds true for any $N \geq N_0$.

Let $(X_\mu)_{\mu \in E}$ be any families of time dependent vector fields $X_\mu$ and let $(g_{j,\mu})_{\mu \in E}$, $0 \leq j \leq N - 1$, be any families of maps such that $X_\mu$ and $(g_{j,\mu})_{0 \leq i \leq N-1}$ satisfy assumptions (i) and (ii) of Lemma 3.1 for every $\mu \in E$. Then each of the composition $g_{N-1,\mu} \circ \ldots \circ g_{0,\mu}$ is well defined on $V_2$ and satisfies the following estimate with the flow $\phi^{0,1}_\mu$ of $X_\mu$:

$$\sup_{V_2} \left\| \phi^{0,1}_\mu - g_{N-1,\mu} \circ \ldots \circ g_{0,\mu} \right\| < \exp(L) \cdot \varepsilon_N. $$

Now assume that $V_2 \subset V_1 \subset V_0$ are complex extension of a compact real analytic manifold $V$ and that $E$ is of the form $E = \mathcal{P}_1 \times \hat{\mathcal{P}}_2$ where $\mathcal{P}_1$ is a compact set and $\hat{\mathcal{P}}_2$ a complex extension of an analytic compact manifold $\mathcal{P}_2$. We obtain immediately

Corollary 3.3. For any $L > 0$ and any positive sequence $\varepsilon_N \to 0$, there is $N_0$ such that the following property holds true for any $N \geq N_0$. Let $(X_\mu)_{\mu \in \mathcal{P}}$ be any families of time dependent $C^\omega$-vector fields on $V$ and let $(g_{j,\mu})_{\mu \in \mathcal{P}}$, $0 \leq j \leq N - 1$, be any continuous families of $C^\omega$ maps of $V$ which all extend to $\mathcal{P}_1 \times \hat{\mathcal{P}}_2$ and such that $X_\mu$ and $(g_{j,\mu})_{0 \leq i \leq N-1}$ satisfy assumptions (i) and (ii) of Lemma 3.1 for every $\mu \in \mathcal{P}_1 \times \hat{\mathcal{P}}_2$. Then each of the composition $g_{N-1,\mu} \circ \ldots \circ g_{0,\mu}$ is well defined on $V_2$ and satisfies the following estimate with the flow $\phi^{0,1}_\mu$ of $X_\mu$:

$$\sup_{V_2} \left\| \phi^{0,1}_\mu - g_{N-1,\mu} \circ \ldots \circ g_{0,\mu} \right\| < \exp(L) \cdot \varepsilon_N. $$
