Twisted Witt Groups of Flag Varieties

Marcus Zibrowius*

29th May 2013

Abstract

Calme’s and Fasel have shown that the twisted Witt groups of split flag varieties vanish in a large number of cases. For flag varieties over algebraically closed fields, we sharpen their result to an if-and-only-if statement. In particular, we show that the twisted Witt groups vanish in many previously unknown cases. In the non-zero cases, we find that the twisted total Witt group forms a free module of rank one over the untwisted total Witt group, up to a difference in grading.

Our proof relies on an identification of the Witt groups of flag varieties with the Tate cohomology groups of their K-groups, whereby the verification of all assertions is eventually reduced to the computation of the (twisted) Tate cohomology of the representation ring of a parabolic subgroup.

Introduction

Let $G$ be a split semisimple algebraic group with a parabolic subgroup $P$. Our object of study is the Witt cohomology of the flag variety $G/P$. Specifically, we address the following question:

Given the untwisted Witt groups $W^i(G/P)$, what can we say about the Witt groups $W^i(G/P, \mathcal{L})$ with twists in a line bundle $\mathcal{L}$ over $G/P$?

A result of Calmès and Fasel shows that in many cases there is a short answer that does not even depend on the untwisted Witt groups: the twisted Witt groups are simply zero [CF12]. The cases they deal with can be described as follows. Suppose $P$ is the standard parabolic subgroup corresponding to a subset $\Theta$ of a set of simple roots $\Sigma$ of $G$. Consider the Dynkin diagram of $G/P$, i.e. the Dynkin diagram of $G$ in which the roots contained in $\Theta$ and $\Sigma - \Theta$ are indicated using different colours, say black for the roots in $\Theta$ and white for the remaining roots\(^1\). For example, the Dynkin diagram of the Grassmannian of three-planes in eight-dimensional space would be:

```
       - - - - - - -
```

Then there is a natural one-to-one correspondence between the white nodes and a basis of the Picard group modulo squares $\text{Pic}(G/P)/2$. Let $\mathfrak{R} \subset \text{Pic}(G/P)/2$ be the linear subspace generated by the basis elements corresponding to those white nodes that have a black neighbour, i.e. that are connected to at least one black node by an edge of the Dynkin diagram. Calmès and Fasel’s result can be paraphrased as follows:

If the class of $\mathcal{L}$ in $\text{Pic}(G/P)/2$ lies outside the subspace $\mathfrak{R}$, then $W^i(\text{Pic}(G/P), \mathcal{L})$ vanishes for all $i$.

For example, for a full flag variety $G/B$ with $B \subset G$ a Borel subgroup, the Dynkin diagram of $G/B$ has white nodes only, the subspace $\mathfrak{R}$ is trivial and the result therefore says that all twisted Witt groups vanish. This has been used by Yagita to identify the untwisted Witt ring $W^*(G/B)$ with the Witt ring of $G$ [Yag11, Theorem 1.1]. However, although Calmès and Fasel’s result covers a great many cases, it is not as sharp as possible. For example, as the authors themselves note, it does not predict the vanishing of all twisted Witt groups of the Grassmannian above. (They are known to vanish by [BC12].)

In this paper, we sharpen Calmès and Fasel’s criterion under the assumption that the ground field is algebraically closed as follows: we describe generators of a smaller linear subspace $\mathfrak{S} \subset \mathfrak{R}$ such that the total twisted Witt group $W^*(G/P, \mathcal{L}) := \bigoplus W^i(G/P, \mathcal{L})$ is non-zero if and only if the reduction of $\mathcal{L}$ modulo two is contained in $\mathfrak{S}$. In addition to the Grassmannian above, here are the Dynkin diagrams of some further examples for which $\mathfrak{S}$, unlike $\mathfrak{R}$, turns out to be trivial:

```
       - O

       O

       - - - - -
```

We also have the following structural result concerning the non-zero cases:

\(^1\)This colouring scheme follows [CF12]. It is inverse to the colouring scheme used in [Zib11, Table 2] and \(\S\) 23.3 of [FH91].
Theorem. If one of the twisted groups \( W^i(G/P, \mathcal{L}) \) is non-zero, then there exists an element \( \zeta \in W^0(G/P, \mathcal{L}) \oplus W^2(G/P, \mathcal{L}) \) such that multiplication with \( \zeta \) induces an isomorphism
\[
W^*(G/P) \cong W^*(G/P, \mathcal{L}).
\]

The element \( \zeta \) is not always homogeneous, so this isomorphism does not necessarily preserve the \( \mathbb{Z}/4 \)-grading of the total Witt group. It only preserves the \( \mathbb{Z}/2 \)-grading consisting of an even part \( W^0 \oplus W^2 \) and an odd part \( W^1 \oplus W^3 \).

Our proof exploits the relationship between Witt groups and the Tate cohomology of K-groups advocated in [Zib12]. Given a variety \( X \), let \( * \) denote the involution on its algebraic K-group \( K_0(X) \) induced by the duality on vector bundles, and let
\[
h^+(X) := \ker(\text{id} - *) / \text{im}(\text{id} + *) \quad \text{and} \quad h^-(X) := \ker(\text{id} + *) / \text{im}(\text{id} - *)
\]
denote the Tate cohomology of \( (K_0(X), *) \). We show:

Theorem. For any smooth cellular variety over an algebraically closed field of characteristic not two, we have isomorphisms
\[
h^+(X) \cong W^0(X) \oplus W^2(X) \quad \text{and} \quad h^-(X) \cong W^1(X) \oplus W^3(X)
\]

This theorem and some related results of Section 2.1 have already been used in [Zib12] to obtain a description of the untwisted Witt rings of full flag varieties. Unfortunately, the assumption that the ground field is algebraically closed is essential in our approach: there is no chance for the relationship between Witt groups and Tate cohomology to hold over an arbitrary field in the form stated as Tate cohomology is always two-torsion. This is the reason why said assumption enters all results on Witt groups presented here. However, each result has a precursor in terms of Tate cohomology which we prove without this assumption.

Apart from being valid over arbitrary fields, Calmès and Fasel’s approach has another competitive advantage: not only is it much easier to state, but also the whole proof fits onto two pages. However, it should be noted that a key input of their argument is an existing ‘vanishing result’ given by Walter’s calculations of the Witt groups of projective bundles [Wal03b]. The approach presented here does not presuppose any existing Witt group computations.

Acknowledgements

I warmly thank Baptiste Calmès and Jean Fasel for many interesting discussions and for sharing their ideas on the problem considered here. In particular, their unpublished computations of Witt groups through cellular spectral sequences have helped me track down mistakes in an earlier version of this article. They also have an independent proof of the above theorem relating Witt groups and Tate cohomology.
1 Statement of the results

1.1 A structure theorem

Given a smooth variety $X$ over a field of characteristic not two, we write $W^i(X)$ to denote the $i$th shifted Witt group of the derived category of vector bundles over $X$ equipped with the usual duality $\mathcal{E} \mapsto \text{Hom}(\mathcal{E}, \mathcal{O}_X)$ [Bal00,Bal01]. More generally, given a line bundle $L$ over $X$, we write $W^i(X, L)$ to denote the corresponding 'twisted' Witt groups of $X$, i.e. the Witt groups of the same category equipped with the duality $\mathcal{E} \mapsto \text{Hom}(\mathcal{E}, L)$. As there are canonical isomorphisms $W^i(X, L) \cong W^{i+1}(X, L)$, we will index these groups with $i \in \mathbb{Z}/4$ in the following. We define the total $L$-twisted Witt group of $X$ as the direct sum

$$W^*(X, L) := \bigoplus_{i \in \mathbb{Z}/4} W^i(X, L).$$

Again, when $L = \mathcal{O}_X$, we simply write $W^*(X)$. These total Witt groups obviously have a natural $\mathbb{Z}/4$-grading. However, we will sometimes forget half of this grading and consider them to be only $\mathbb{Z}/2$-graded with homogeneous parts $W^{0,2}$ and $W^{1,3}$ defined in the obvious way:

$$W^{0,2}(X, L) := W^0(X, L) \oplus W^2(X, L)$$
$$W^{1,3}(X, L) := W^1(X, L) \oplus W^3(X, L)$$

For any line bundles $L$ and $M$, we have a pairing

$$W^i(X, L) \otimes W^j(X, M) \to W^{i+j}(X, L \otimes M)$$

such that $W^*(X)$ is a ($\mathbb{Z}/4$- or $\mathbb{Z}/2$-)graded ring over which the twisted total Witt groups are graded modules [GN03]. It follows easily from the definitions that any line bundle $L$ over $X$ defines a class $[L]$ in $W^0(X, L^2)$ such that multiplication with $[L]$ induces an isomorphism

$$W^*(X, L^2) \cong W^*(X, L)$$

and more generally isomorphisms $W^*(X, N) \cong W^*(X, N \otimes L^2)$. In particular, the $L$-twisted Witt groups of $X$ only depend on the class of $L$ in $\text{Pic}(X)/2$.

For twists by a line bundle $L$ that cannot be expressed as a tensor square, we are not aware of any general results concerning the relationship of $W^*(X, L)$ to $W^*(X)$. However, it turns out that when $X$ is a flag variety, there are only two possibilities: either the total twisted Witt group vanishes, or it is free of rank one as a $\mathbb{Z}/2$-graded module over $W^*(X)$. Here and in the following, by a flag variety we mean a quotient $G/P$ of a split semisimple algebraic group $G$ by a parabolic subgroup $P$.

1.1 Structure Theorem. Let $L$ be a line bundle over a flag variety $G/P$ over an algebraically closed field of characteristic not two. If the twisted total Witt group $W^*(G/P, L)$ is non-zero, then there exists an element $\zeta_L$ in $W^{0,2}(G/P, L)$ such that multiplication by $\zeta_L$ induces an isomorphism of $\mathbb{Z}/2$-graded modules

$$W^*(G/P) \cong_{\zeta_L} W^*(G/P, L).$$

Moreover, if both $W^*(G/P, L_1)$ and $W^*(G/P, L_2)$ are non-zero for line bundles $L_1$ and $L_2$, then so is $W^*(G/P, L_1 \otimes L_2)$ and we may choose $\zeta_{L_1 \otimes L_2} = \zeta_{L_1} \cdot \zeta_{L_2}$.

In particular, in the cases when the total $L$-twisted Witt group is non-zero, we have isomorphisms

$$W^{0,2}(G/P) \cong W^{0,2}(G/P, L) \quad \text{and} \quad W^{1,3}(G/P) \cong W^{1,3}(G/P, L).$$
The failure of these isomorphisms to respect the finer \( \mathbb{Z}/4 \)-grading can already be seen for the most simple examples of flag varieties, as illustrated by Table 1.

\textbf{Remark.} Essentially, Structure Theorem 1.1 says that the total Witt group \( W^*(G/P, \mathcal{L}) \) behaves like the space of solutions to a linear system of equations with constant term \( \mathcal{L} \). This is no coincidence: our proof will eventually reduce to this situation in linear algebra.

### 1.2 A vanishing theorem

We will describe for which line bundles the twisted Witt groups vanish using a graphical notation that we now explain. Let \( T \) be a split maximal torus of \( G \), and let \( X^* := X^*(T) \) be its character group, the weight lattice of \( G \). We write \( R \subset X^* \) for the set of roots of \( G \), and we chose a set of simple roots \( \Sigma \).

Note first that any flag variety under \( G \) is also a flag variety under its simply connected cover. So we may and will assume that \( G \) is simply connected. Different simply connected semisimple groups \( G \) are determined up to isomorphism their Dynkin diagram.

Next, we have a one-to-one correspondence between subsets \( \Theta \subset \Sigma \) and conjugacy classes of parabolic subgroups of \( G \). Thus, we can specify \( G/P \) up to isomorphism by drawing the Dynkin diagram of \( G \) with those nodes corresponding to the roots in \( \Theta \) coloured, as in the introduction. For example, the diagram

\[ \circ - \bullet - \circ - \circ - \bullet - \circ \]

will denote the quotient of the simply connected semisimple group of type \( B_7 \) by a parabolic subgroup corresponding to a two-element subset of \( \Sigma \). The subdiagram consisting of all black nodes and edges between them is the Dynkin diagram of the Levi subgroup of \( P \) (c.f. Section 3.2).

A standard representative of the conjugacy class corresponding to a subset \( \Theta \subset \Sigma \) is given by the subgroup \( P_\Theta \) of \( G \) generated by the maximal torus \( T \), the root subgroups of all negative roots, and the root subgroups of all positive roots contained in \( \mathbb{Z}\Theta \). We will assume from now on that \( P \) is of this form.

The Picard group of \( G/P \) is a free abelian group on line bundles \( \mathcal{L}_\beta \) corresponding to the simple roots in \( \Sigma - \Theta \), i.e. to the white nodes of our diagram. This correspondence can be described as follows: Let \( \{ \omega_\sigma \mid \sigma \in \Sigma \} \) be the set of fundamental weights. As we have assumed \( G \) to be simply connected, these are actual characters of \( T \) and not just elements of \( X^* \otimes \mathbb{Q} \). Those fundamental weights \( \omega_\beta \) with \( \beta \in \Sigma - \Theta \) extend to characters of \( P = P_\Theta \) and hence define line bundles \( \mathcal{L}_\beta \) over \( G/P \).
We can thus specify a line bundle \( L_\beta \) over \( G/P \) by drawing a 'line mark' over the node corresponding to \( \beta \) in the Dynkin diagram of \( G/P \), like so:

More generally, we will use a line mark connecting several such nodes to specify a tensor product of the corresponding line bundles. For example,

will denote the two line bundles \( L_{\beta_1} \otimes L_{\beta_3} \) and \( L_{\beta_2} \) on \( G/P(\alpha_1, \alpha_2) \).

By the second part of Structure Theorem 1.1, the classes in \( \text{Pic}(G/P)/2 \) of all line bundles \( \mathcal{L} \) for which \( W^*(G/P, \mathcal{L}) \) is non-zero form a linear subspace. The idea of our vanishing theorem is to describe a set of generators of this subspace by specifying the corresponding line marks of the Dynkin diagram of \( G/P \). The precise rules for obtaining these marks are laid out in the next section.

1.2 Vanishing Theorem. Let \( \mathcal{L} \) be a line bundle over a flag variety \( G/P \) as in Structure Theorem 1.1. Assume without loss of generality that \( G \) is simply connected, and that we have chosen a set of simple roots \( \Sigma \) such that \( P \) is the standard parabolic subgroup corresponding to a subset \( \Theta \subset \Sigma \). Then the \( \mathcal{L} \)-twisted total Witt group \( W^*(G/P, \mathcal{L}) \) is non-zero if and only if the reduction of \( \mathcal{L} \) modulo two is a linear combination of the line bundles marked in the Dynkin diagram of \( G/P \) according to the marking scheme below.

1.3 A marking scheme

Let \( G/P \) and \( \Theta \subset \Sigma \) be as in Structure Theorem 1.1. We use the same letters to denote the corresponding Dynkin diagrams, i.e. \( \Sigma \) for the Dynkin diagram of \( G \) and \( \Theta \) for the subdiagram spanned by the black nodes. A connected component \( \Theta_0 \) of \( \Theta \) determines line marks only on the connected component \( \Sigma_0 \) of \( \Sigma \) in which it is contained. Moreover, the line marks determined by different connected components of \( \Theta \) are independent. The line marks determined by a connected component \( \Theta_0 \) depend both on the types of \( \Theta_0 \) and \( \Sigma_0 \) and the relative position of \( \Theta_0 \) within \( \Sigma_0 \), as follows:

\( \Sigma_0 \) of type \( A_n \)

\( \Theta_0 \) of type \( A_1 \) with \( l \) odd

Connect all neighbours of \( \Theta_0 \) with a single mark. That is:

If \( \Theta_0 \) has a unique neighbour, mark that neighbour.
If \( \Theta_0 \) has two neighbours, connect these with a mark.

(Subdiagrams of type \( A_l \) with \( l \) even do not contribute any marks.)

\( \Sigma_0 \) of type \( B_n \)

\( \Theta_0 \) of type \( A_1 \) with \( l \) odd

Connect all neighbours of \( \Theta_0 \) with a single mark, except for the unique shortest root \( \sigma_n \) of \( \Sigma_0 \). This root is never marked.

\( \Theta_0 \) of type \( B_l \) Mark the unique neighbour (for \( l \neq n \)).

(Subdiagrams of type \( A_l \) with \( l \) even do not contribute any marks.)

The following two examples illustrate the marking scheme in this case:
Σ₀ of type Cₙ

Θ₀ of type A₁ with l odd
Connect all neighbours of Θ₀ with a single mark.

(Subdiagrams of types Aₗ with l even, B₂ and C₁ do not contribute any marks.)

Σ₀ of type Dₙ

Θ₀ of type A₁, l odd
Connect all neighbours of the two outer roots of Θ₀ with a mark.

Θ₀ of type D₁, l even Mark the unique neighbour.

(Subdiagrams of types Aₗ with l even and D₁ with l odd do not contribute any marks.)

Σ₀ of type Eₙ (n ∈ {6, 7, 8})

Θ₀ of type A₁, l odd
Connect all neighbours of the two outer roots of Θ₀ with a mark.

If l = 5, (also) mark the unique neighbour of the central root of Θ₀.
If l = 7, (also) mark the unique neighbour of the central root of Θ₀.

Θ₀ of type D₄, D₆ Mark all neighbours (one or two) individually.

Θ₀ of type D₅, D₇ Mark the root σ₁ of Σ₀ if it is a neighbour of Θ₀.

(Subdiagrams of types A₂, A₄ and Eₙ do not contribute any marks.)

Σ₀ of type F₄ Distribute marks according to the following diagrams:

Σ₀ of type G₂

A₁ ⊂ G₂ Mark the unique neighbour.

Note that all diagrams mentioned in the introduction remain undecorated according to this marking scheme.
2 From Witt rings to representation rings

In this section we explain how we translate the computation of Witt rings of flag varieties to a computation with representation rings. First, in Section 2.1, we show that the Witt ring of a smooth cellular variety over an algebraically closed field may be identified with the Tate cohomology of its K-ring. Here, by a cellular variety we mean a variety $X$ which can be equipped with a filtration by closed subsets

$$X = X^0 \supset X^1 \supset X^2 \supset \cdots$$

such that each complement $X^i - X^{i+1}$ is isomorphic to affine space $A^{n_i}$ for some $n_i$. Flag varieties are among the main examples of varieties with this property [Koc91, Proposition (1.3)]. In Section 2.2, we briefly recall the well-known representation-theoretic description of their K-rings.

2.1 Witt rings as Tate cohomology rings

Let $(\mathcal{D}, *, \omega)$ be a triangulated category with duality in the sense of [Bal00]. Then the duality functor $*$ induces an involution on the K-group $K(\mathcal{D})$, which we still denote $*$. The associated Tate cohomology groups are defined as

$$h^i(K(\mathcal{D}), *) := \frac{\ker(id - (-1)^i *)}{\im(id + (-1)^i *)}$$

As these groups depend only on the parity of $i$, we also use the notation

$$h^+(K(\mathcal{D}), *) := h^0(K(\mathcal{D}, *))$$

$$h^-(K(\mathcal{D}), *) := h^1(K(\mathcal{D}, *))$$

and write $h^*(K(\mathcal{D}), *)$ for the $\mathbb{Z}/2$-graded group $h^+(K(\mathcal{D}), *) \oplus h^-(K(\mathcal{D}), *)$.

Let $GW^i(\mathcal{D})$ denote the $i$th shifted Grothendieck-Witt group of $(\mathcal{D}, *, \omega)$ and let $F^i : GW^i(\mathcal{D}) \to K(\mathcal{D})$ and $H^i : K(\mathcal{D}) \to GW^i(\mathcal{D})$ denote the forgetful and hyperbolic maps, respectively. By [Wal03a] they fit into fundamental exact sequences

$$GW^{i-1}(\mathcal{D}) \xrightarrow{F^{i-1}} K(\mathcal{D}) \xrightarrow{H^i} GW^i(\mathcal{D}) \to W^i(\mathcal{D}) \to 0. \quad (1)$$

In particular, $H^i F^{i-1} = 0$, and the cokernel $GW^i(\mathcal{D})/H^i$ may be identified with the Witt group $W^i(\mathcal{D})$. The forgetful and hyperbolic maps interact with the involution on $K(\mathcal{D})$ in the following way:

$$H^i * = (-1)^i H^i$$

$$F^i H^i = \id + (-1)^i *$$

$$* F^i = (-1)^i F^i$$

These equations have the following consequence:

2.1 Lemma. For any triangulated category with duality $(\mathcal{D}, *, \omega)$, the hyperbolic and forgetful maps induce well-defined maps

$$W^0(\mathcal{D}) \oplus W^2(\mathcal{D}) \xrightarrow{(F^0, F^2)} h^+(K(\mathcal{D}), *) \xrightarrow{H^i} \ker F^{i-1} \oplus \ker F^i$$

$$W^1(\mathcal{D}) \oplus W^3(\mathcal{D}) \xrightarrow{(F^1, F^3)} h^-(K(\mathcal{D}), *) \xrightarrow{H^i} \ker F^0 \oplus \ker F^2$$

The two horizontal compositions are of the form \( \begin{pmatrix} H^i & F^i \\ 0 & H^{i+2} F^{i+2} \end{pmatrix} \). \qed
Here is a simple scenario in which these maps are isomorphisms:

**2.2 Theorem.** Let \( \mathcal{D} \) be the derived category of a \( k \)-linear abelian category with an exact \( k \)-linear duality \( (\mathcal{A}, *, \omega) \), where \( k \) is an algebraically closed field of characteristic not two. Suppose that all objects of \( \mathcal{A} \) have finite length. Then the maps \((F^i, F^{i+2})\) and \((R^i, R^{i+2})\) of Lemma 2.1 are isomorphisms.\(^2\)

This theorem applies for instance to the category of finite-dimensional linear representations of an affine algebraic group over an algebraically closed field. Strictly speaking, we will not use this result in the sequel. We include it here partly because it puts Theorem 2.3 below into perspective, and partly because it has a simple, illustrative proof.

Now let \( X \) be variety over a field of characteristic not two. For any line bundle \( \mathcal{L} \) over \( X \), we can consider the category with duality \((\mathcal{D}(X), *_{\mathcal{L}}, \omega)\), the derived category of the category of vector bundles over \( X \) equipped with the duality \(*_{\mathcal{L}}\) induce by \( \mathcal{E} \mapsto \text{Hom}(\mathcal{E}, \mathcal{L}) \) and the usual double-dual identification \( \omega \). Then \( K(\mathcal{D}(X)) \) is the usual \( K \)-group \( K_0(X) \) of \( X \), equipped with an induced involution \(*_{\mathcal{L}}\) for each line bundle \( \mathcal{L} \) over \( X \). To simplify notation, we define

\[
\begin{align*}
  h^*(X) &:= h^*(K_0(X), *_{\mathcal{O}_X}) \\
  h^*(X, \mathcal{L}) &:= h^*(K_0(X), *_{\mathcal{L}})
\end{align*}
\]

For any two line bundles \( \mathcal{L}_1 \) and \( \mathcal{L}_2 \), the ring structure on \( K_0(X) \) induces a pairing

\[
h^i(X, \mathcal{L}_1) \otimes h^j(X, \mathcal{L}_2) \to h^{i+j}(X, \mathcal{L}_1 \otimes \mathcal{L}_2)
\]

such that \( h^*(X) \) is a \( \mathbb{Z}/2 \)-graded ring, and such that \( h^*(X, \mathcal{L}) \) is a graded \( h^*(X) \)-module (c.f. Lemma 4.1).

**2.3 Theorem.** Let \( X \) be a smooth cellular variety over an algebraically closed field of characteristic not two, and let \( \mathcal{L} \) be a line bundle over \( X \). Then for \((\mathcal{D}, *, \omega) := (\mathcal{D}(X), *_{\mathcal{L}}, \omega)\) as above, the maps in Lemma 2.1 are isomorphisms. In particular, we have isomorphisms\(^3\)

\[
\begin{align*}
  W^{0,2}(X, \mathcal{L}) &\cong h^+(X, \mathcal{L}) \\
  W^{1,-3}(X, \mathcal{L}) &\cong h^-(X, \mathcal{L})
\end{align*}
\]

When \( \mathcal{L} \) is trivial, these group isomorphisms assemble to an isomorphism of \( \mathbb{Z}/2 \)-graded rings \( W^*(X) \cong h^*(X) \). More generally, for any two line bundles \( \mathcal{L}_1 \) and \( \mathcal{L}_2 \) over \( X \), these isomorphisms are compatible with the respective pairings in the sense that

\[
\begin{align*}
  W^{i,j+2}(X, \mathcal{L}_1) \otimes W^{j,j+2}(X, \mathcal{L}_2) &\to W^{i+j,j+2}(X, \mathcal{L}_1 \otimes \mathcal{L}_2) \\
  h^i(X, \mathcal{L}_1) \otimes h^j(X, \mathcal{L}_2) &\to h^{i+j}(X, \mathcal{L}_1 \otimes \mathcal{L}_2)
\end{align*}
\]

commutes.

The proofs of Theorems 2.2 and 2.3 occupy the remainder of this section.

**Proof of Theorem 2.2.** As two is assumed to be invertible, we can identify \( W^0(\mathcal{D}) \) and \( W^2(\mathcal{D}) \) with the usual Witt groups of symmetric and anti-symmetric objects \( W^0(\mathcal{A}) \) and \( W^2(\mathcal{A}) \) [Bal01, Theorem 4.3], and likewise

\(^2\)Note that the groups \( W^1(\mathcal{D}) \), \( W^3(\mathcal{D}) \) and \( h^-(\mathcal{K}(\mathcal{D}), *) \) vanish in this setting.

\(^3\)Recall that we write \( W^{i,i+2}(X, \mathcal{L}) \) for \( W^i(X, \mathcal{L}) \oplus W^{i+2}(X, \mathcal{L}) \).
for the Grothendieck-Witt groups $GW^0(D)$ and $GW^2(D)$. Moreover, by Proposition 5.2 of [BW02], $W^1(D) = W^3(D) = 0$.

Choose a set $S$ of representatives of the simple objects of $A$. As $k$ is algebraically closed, every such object has $k$ as endomorphism ring, and every self-dual simple object is either symmetric or anti-symmetric [CH04, Lemma 1.21]. Let $S_+, S_- \subseteq S$ be the subsets of symmetric and anti-symmetric objects, and let $S_0$ contain one object of each pair $(S, S^*)$ of non-self-dual objects of $S$. Given any object $A$ of $A$, let $A_A$ denote the full subcategory on objects isomorphic to direct summands of finite direct sums of copies of $A$. The inclusions of $A_S$ and $A_{S\oplus S\cdot}$ into $A$ induce isomorphisms

$$K(A) \cong \bigoplus_{S \in S_+} K(A_S) \oplus \bigoplus_{S \in S_-} K(A_S) \oplus \bigoplus_{S \in S_0} K(A_{S\oplus S\cdot}).$$

Moreover, as the duality on $A$ restricts to $A_S$ (for self-dual $S$) and to $A_{S\oplus S\cdot}$ (for arbitrary $S$), we have analogous decompositions for $GW^0(A)$, $GW^2(A)$, $W^0(A)$ and $W^2(A)$ [QSS79, Theorem 6.10, CH04, Corollary 1.14]. Moreover, these decompositions are compatible with the hyperbolic and forgetful maps $F'$ and $H'$. It follows that we have such decompositions for all $GW^i(D)$ and $W^i(D)$, with each category $A_A$ replaced by its derived category $D_A$. Thus, it suffices to prove the theorem for each category $A_S$ with $S \in S_+$ or $S_-$ and each category $A_{S\oplus S\cdot}$ with $S \in S_0$.

For $S \in S_+$, we have $K(A_S) \cong K(k)$, $GW^0(A_S) \cong GW^0(k)$ and $GW^2(A_S) \cong GW^2(k)$ [QSS79, Proposition 2.4]. The groups $K(k)$ and $GW^2(k)$ are equal to $\mathbb{Z}$ for any field $k$; as $k$ is algebraically closed, the same is true for $GW^0(k)$. The proof of Proposition 2.4 in [QSS79] also yields explicit generators for each of these groups: if we choose some fixed symmetry $\sigma$ on $S$, we can write:

$$K(A_S) = \mathbb{Z} \cdot [S]$$
$$GW^0(A_S) = \mathbb{Z} \cdot [S, \sigma]$$
$$GW^2(A_S) = \mathbb{Z} \cdot [H^2S]$$

The exact sequences (1) therefore take the following form:

$Z/2[H^1S] \xrightarrow{F'} Z[S] \xrightarrow{H'} Z[S, \sigma] \rightarrow Z/2[S, \sigma] \rightarrow 0$

$Z[S, \sigma] \xrightarrow{F'} Z[S] \xrightarrow{H'} 0 \rightarrow 0$

$0 \xrightarrow{F'} Z[S] \xrightarrow{H'} Z[H^2S] \rightarrow 0$

$Z[H^2S] \xrightarrow{F'} Z[S] \xrightarrow{H'} Z/[H^1S] \rightarrow 0$

As the involution on $Z[S]$ is trivial, $h^+(Z[S]) = Z/2[S]$, and the claims that the maps $(F', F^{i+2})$ and $(H', H^{i+2})$ are isomorphisms are easily checked.

The proof for $S \in S_-$ is analogous. In this case, the exact sequences (1) take the following form, where $\sigma$ is some fixed anti-symmetry on $S$:

$0 \xrightarrow{F'} Z[S] \xrightarrow{H'} Z[H^0S] \rightarrow 0$

$Z[H^0S] \xrightarrow{F'} Z[S] \xrightarrow{H'} Z/[H^1S] \rightarrow 0$

$Z/2[H^1S] \xrightarrow{F'} Z[S] \xrightarrow{H'} Z[S, \sigma] \rightarrow Z/2[S, \sigma] \rightarrow 0$

$Z[S, \sigma] \xrightarrow{F'} Z[S] \xrightarrow{H'} 0 \rightarrow 0$

Finally, for $A_{S\oplus S\cdot}$ with $S \in S_0$, all groups involved in Lemma 2.1 vanish. In slightly more detail, the Grothendieck-Witt groups of $A_{S\oplus S\cdot}$ can be identified
with the Grothendieck-Witt groups of the ring with involution \((k \times k, \circ)\), where
\(\circ\) interchanges the two factors. Any finitely-generated module over \(k \times k\) can
be written as \(V_1 \oplus V_2\) for \(k\)-vector spaces \(V_1\) and \(V_2\), with the first factor of
\(k \times k\) acting trivially on \(V_2\) and the second factor acting trivially on \(V_1\). In this
notation, the dual of \(V_1 \oplus V_2\) is \(V_2^* \oplus V_1^*\), where \((-)^*\) denotes the usual
duality on vector spaces. It follows that any (anti-)symmetric module over \((k \times k, \circ)\)
is necessarily hyperbolic (c.f. [CH04, Theorem 1.28]). Thus, in this case the
exact sequences (1) take the following form:

\[
\begin{align*}
Z[H^{-1}S] & \xrightarrow{F^{-1}} Z[S] \oplus Z[S^*] \xrightarrow{H^n} Z[H^0S] \to 0 \\
Z[H^0S] & \xrightarrow{F^0} Z[S] \oplus Z[S^*] \xrightarrow{H^1} Z[H^1S] \to 0 \\
Z[H^1S] & \xrightarrow{F^1} Z[S] \oplus Z[S^*] \xrightarrow{H^2} Z[H^2S] \to 0 \\
Z[H^2S] & \xrightarrow{F^2} Z[S] \oplus Z[S^*] \xrightarrow{H^{-1}} Z[H^{-1}S] \to 0
\end{align*}
\]

In particular, all the maps \(F^i\) are injective and all Witt groups are zero, in
agreement with the fact that \(h^*(Z[S] \oplus Z[S^*])\) vanishes. \(\square\)

For the proof of Theorem 2.3, we use a couple of lemmas.

2.4 Lemma. Let \(A \xrightarrow{r} B \xrightarrow{s} C\) be a short exact sequence of triangulated
categories with duality with the property that

\[0 \to K(A) \to K(B) \to K(C) \to 0\]

is exact. Then the forgetful functors \(F^i\) commute with the boundary maps in the
associated long exact sequence of Witt groups and the long exact group
cohomology sequence, i.e. the following square commutes:

\[
\begin{array}{ccc}
W^i(C) & \xrightarrow{\partial} & W^{i+1}(A) \\
\xrightarrow{F^i} & & \xrightarrow{F^{i+1}} \\
h^i(C) & \xrightarrow{\partial} & h^{i+1}(A)
\end{array}
\]

Proof. The boundary map on Witt groups is defined as follows [Bal00, Def. 4.16]: \(^4\) Any element of \(W^i(C)\) can be represented by the image \(r(B, \beta)\)
of some \(i\)-symmetric pair \((B, \beta)\) in \(B\). Then the cone of \(\beta : B \to B^*[i]\) is
isomorphic to zero in \(C\), so it lies in \(A\). It may be equipped with some
\((i+1)\)-symmetric form \(\gamma\), and we have \(\partial[r(B, \beta)] := [\text{cone}(\beta), \gamma]\). In particular,
\(F\partial[r(B, \beta)] = [\text{cone}(\beta)]\).

The boundary map from \(h^i(C)\) to \(h^{i+1}(A)\), on the other hand, sends \([rB]\) to
\([B] - (-1)^i[B^*]\), which we may view as an element of \(K(A)\). This element agrees
with \([\text{cone}(\beta)]\) in \(K(B)\), so we conclude using the injectivity of \(K(A) \to K(B)\).

\(\square\)

2.5 Lemma. Let \(Z \hookrightarrow X\) be a closed embedding of smooth quasi-projective
varieties over a field of characteristic not two. Then the forgetful functor commutes with the Thom isomorphism of [Nen07], i.e. we have commutative
diagrams of the form

\[
\begin{array}{ccc}
W^{i-c}(Z, \mathcal{L}|_Z \otimes \det N) & \xrightarrow{\sim} & W^i_Z(X, \mathcal{L}) \\
\xrightarrow{F^{-c}} & & \xrightarrow{F^i} \\
h^{i-c}(Z, \mathcal{L}|_Z \otimes \det N) & \xrightarrow{\sim} & h^i_Z(X, \mathcal{L})
\end{array}
\]

\(^4\)C.f. [BG05, § 2] for a concise summary in the case of vector bundles over varieties.
Here, $c$ and $\mathcal{N}$ are the codimension and the normal bundle of $Z \hookrightarrow X$. We have written $h^\ast_{\mathcal{Z}}(X, \mathcal{L})$ for the Tate cohomology $h^\ast(K^\mathbb{Z}_0(X), \ast \mathcal{L})$.

**Proof.** A review of the construction of the Thom isomorphism shows that the claim already holds on the level of Grothendieck-Witt and K-groups: Let $K(\mathcal{N})$ denote the Koszul complex of $\mathcal{N}$ as described in [Nen07, §2]. This is a complex of vector bundles over $\mathcal{N}$ whose cohomology is supported on the zero section $Z$. It carries a canonical $c$-symmetric form

$$\Theta(\mathcal{N}): K(\mathcal{N}) \xrightarrow{\sim} K(\mathcal{N})^* [c] \otimes p^* \det \mathcal{N}^*,$$

where $p$ denotes the bundle projection $\mathcal{N} \twoheadrightarrow Z$. One thus has elements $\kappa := [K(\mathcal{N}), \Theta(\mathcal{N})]$ in $GW^\mathbb{Z}_0(\mathcal{N}, \det p^* \mathcal{N}^*)$ and $F^\ast(\kappa)$ in $K^\mathbb{Z}_0(\mathcal{N})$. Multiplication with $\kappa$ induces group isomorphisms

$$GW^{i-\varepsilon}(Z, \mathcal{L} \otimes \det \mathcal{N}) \xrightarrow{\sim} GW^i(Z, \mathcal{L})$$

for all line bundles $\mathcal{L}$ over $Z$, while multiplication with $F^\ast(\kappa)$ induces the usual Thom-isomorphism of K-groups $K_0(Z) \cong K_0^\mathbb{Z}(X)$. If we want to view this as an isomorphism of groups with involution, we need to take care both of the sign and the twist of the involution. So let $K_0(X, -\mathcal{L})$ denote $K_0(X)$ equipped with minus the $\mathcal{L}$-twisted duality (for any $X$ and any $\mathcal{L}$). Then multiplication by $F^\ast(\kappa)$ induces isomorphisms

$$K_0(Z, (-1)^{i-\varepsilon} \mathcal{L} \otimes \det \mathcal{N}) \xrightarrow{\sim} K_0^\mathbb{Z}(\mathcal{N}, (-1)^i p^* \mathcal{L})$$

and, since $F$ is multiplicative, we have commutative diagrams

$$\begin{array}{ccc}
GW^{i-\varepsilon}(Z, \mathcal{L} \otimes \det \mathcal{N}) & \xrightarrow{\sim} & GW^i(Z, \mathcal{L}) \\
\downarrow_{F^\ast} & & \downarrow_{F^i} \\
K_0(Z, (-1)^{i-\varepsilon} \mathcal{L} \otimes \det \mathcal{N}) & \xrightarrow{\sim} & K_0^\mathbb{Z}(\mathcal{N}, (-1)^i p^* \mathcal{L})
\end{array}$$

The Thom-isomorphisms in the lemma are obtained by composing the horizontal arrows with $p^*$. Thus, the lemma follows from the naturality of $F$ and the observation that $h^\ast(K_0(X, (-1)^i \mathcal{L})) = h^{i+1} (X, \mathcal{L})$. \qed

**Proof of Theorem 2.3.** By Lemma 2.6 below, it suffices to show that the maps $(F^i, F^{i+1})$ are isomorphisms. This may be proved by induction over the cells of $X$. Indeed, using Theorem 2.2 or otherwise, we see that the claim is true for $X = \text{Spec}(k)$, where $k$ is an algebraically closed field. Thus, by homotopy invariance, the claim holds for an arbitrary cell $K^a_k$. Now let $X = U_0 \supset U_1 \supset U_2 \cdots \supset U_N = \emptyset$ be a filtration of $X$ by open subsets as in [Zib11, proof of Thm 2.6], i.e. such that the complement of each $U_k+1$ in $U_k$ is a closed cell $Z_k$. For each $k$ we have a short exact sequence of triangulated categories

$$0 \rightarrow \mathcal{D}^b_{Z_k}(U_k) \rightarrow \mathcal{D}^b(U_k) \rightarrow \mathcal{D}^b(U_{k+1}) \rightarrow 0. \quad (2)$$

As the K-group of these categories are free abelian groups on the numbers of cells of $Z_k, U_k$ and $U_k$, respectively, the induced sequence of K-groups

$$0 \rightarrow K^b_{\mathcal{Z}_k}(U_k) \rightarrow K_0(U_k) \rightarrow K_0(U_{k+1}) \rightarrow 0 \quad (3)$$

is still exact. Moreover, if we choose the usual duality on these categories (or if we twist the duality by the restriction of $\mathcal{L}$ in each case) this sequence becomes a short exact sequence of categories with duality. By Lemma 2.4, the associated long exact sequence of Witt groups may be compared to the long exact Tate cohomology sequence induced by (3) via a commutative ladder diagram:
\[ \cdots \xrightarrow{\partial} W^{i-1,i+1}(U_{k+1}) \xrightarrow{\partial} W^{i,i+2}(U_k) \xrightarrow{\partial} W^{i,i+2}(U_{k+1}) \xrightarrow{\partial} W^{i+1,i+3}(U_k) \cdots \]

\[ \cdots \xrightarrow{\partial} h^{i-1}(U_{k+1}) \xrightarrow{\partial} h^i(U_k) \xrightarrow{\partial} h^i(U_{k+1}) \xrightarrow{\partial} h^{i+1}(U_k) \cdots \]

By (backward) induction, we may assume that the vertical maps to \( h^*(U_{k+1}) \) are isomorphisms. By Lemma 2.5 the maps to \( h^i(U_k) \) may be identified with the maps

\[ W^{i-c,i-c+2}(Z_k) \longrightarrow h^{i-c}(Z_k), \]

which are isomorphisms since \( Z_k \cong \mathbb{A}^n \) for some \( n \). So we may conclude that the vertical maps to \( h^*(U_k) \) are also isomorphisms.

Finally, the claim concerning the multiplicative structure follows from the corresponding claim for the forgetful functors, i.e. from the fact that

\[ GW^i(X, \mathcal{L}_1) \otimes GW^j(X, \mathcal{L}_2) \xrightarrow{\partial} GW^{i+j}(X, \mathcal{L}_1 \otimes \mathcal{L}_2) \]

\[ \xrightarrow{F^i \otimes F^j} \]

\[ K_0(X) \otimes K_0(X) \xrightarrow{\partial} K_0(X) \]

commutes.

2.6 Lemma. Let \((\mathcal{D}, \ast, \omega)\) be as in Lemma 2.1. If \((\check{F}^i, \check{F}^{i+2})\) is an isomorphism for all (i.e. for both even and odd) values of \( i \), then so is \( \left( \check{H}^i, \check{H}^{i+2} \right) \).

Proof. To see that \( \left( \check{H}^0, \check{H}^2 \right) \) is injective, suppose that \( H^0(x) = H^2(x) = 0 \) for some anti-self-dual element \( x \in K(D) \). Then by the exactness of sequence (1) there exist elements \( y_{-1} \in GW^{-1}(\mathcal{D}) \) and \( y_1 \in GW^1(\mathcal{D}) \) such that \( x = F^{-1}(y_{-1}) = F^1(y_1) \). Injectivity of \( (\check{F}^{-1}, \check{F}^1) \) then implies that \((y_{-1}, -y_1)\) is zero in \( W^{-1}(\mathcal{D}) \oplus W^1(\mathcal{D}) \). By definition of the Witt group, this means that we may find elements \( z_{-1}, z_1 \in K(D) \) such that \( y_{-1} = H^{-1}(z_{-1}) \) and \( y_1 = H^1(z_1) \). In particular, \( x = F^1(H^1(z_1)) = z_1 - z^\ast_{-1} \). So \( x \) is zero in \( h^0(\mathcal{D}) \).

In order to see that \( \check{H}^0 \) surjects onto \( \ker F^0 \), take an arbitrary element \( x \in GW^0(\mathcal{D}) \) such that \( F^0(x) = 0 \). Injectivity of \( (\check{F}^0, \check{F}^2) \) then implies that \( x \) is zero in \( W^0(\mathcal{D}) \). So \( x = H^0(z) \) for some \( z \in K(D) \). Since \( z + z^\ast = F^0(x) = 0 \), we may consider the class of \( z \) in \( h^0(\mathcal{D}) \). Surjectivity of \( (\check{F}^{-1}, \check{F}^1) \) then implies the existence of elements \( y_{-1} \in \mathcal{W}^{-1}(\mathcal{D}) \) and \( y_1 \in W^1(\mathcal{D}) \) such that \( z = F^{-1}(y_{-1}) + F^1(y_1) \). Applying \( \check{H}^0 \), we find that \( x = \check{H}^0\check{F}^1(y_1) \). Thus, \( (x, 0) = (\check{H}^0, \check{H}^2)(\check{F}^1(y_1)) \). Similarly, \( \check{H}^2 \) surjects onto \( \ker F^2 \), so \( \left( \check{H}^{-1}, \check{H}^2 \right) \) is surjective.

The proof that \( \left( \check{H}^{-1}, \check{H}^1 \right) \) is an isomorphism is analogous.
2.2 K-theory of flag varieties

Theorem 2.3 tells us that the Witt groups of a flag variety $G/P$ are closely related to the Tate cohomology of its algebraic K-group $K_0(G/P)$. The reason why this is useful is that this K-group has a nice description in terms of the representation rings $Rep(G)$ and $Rep(P)$ of $G$ and $P$. A proof of the following algebraic variant of a theorem of Hodgkin [Hod75, Lemma 9.2] has been given by Panin [Pan94]:

2.7 Panin’s Theorem. Let $G$ be a simply connected semisimple algebraic group with a parabolic subgroup $P$. Then we have a ring isomorphism

$$K_0(G/P) \cong Rep(P)/a$$

where $a \subset Rep(P)$ is the ideal generated by restrictions of rank zero classes in $Rep(G)$.

This isomorphism is very geometric: It is induced by the morphism $K_0(G/P) \leftarrow Rep(P)$ that sends a representation $V$ of $P$ to the associated vector bundle $G \times_P V$ over $G/P$ (c.f. [Pan94, §1]). In particular, it respects the involutions on both sides induced by the usual duality on vector bundles and representations, and it restricts to the isomorphism

$$Pic(G/P) \cong X^*(Rep(P))$$

[MT95, Proposition 2.3] under which the line bundle called $L_\beta$ in Section 1.2 corresponds to the character $\omega_\beta$ of $Rep(P)$ (see Section 3.2).

A key ingredient in Panin’s proof is the following theorem of Steinberg [Ste75], which we will also need later:

2.8 Steinberg’s Theorem. The representation ring $Rep(P)$ of a parabolic subgroup of a simply connected semisimple algebraic group $G$ is finite and free as a $Rep(G)$-module.

The remainder of the article is now easily outlined: we work out an explicit description of $Rep(P)$ as a ring with involution, we compute its Tate cohomology, and finally we translate everything back to Witt groups.

3 Representation rings

In this section, we analyse the representation ring of a parabolic subgroup and the involution induced by dualizing representations.

To put the final result in Section 3.5 into perspective, recall that the representation ring of any simply connected semisimple algebraic group can be written as a polynomial ring such that the involution restricts to an involution of the polynomial generators. The representation ring $Rep(P)$ of a parabolic subgroup is a tensor product of a polynomial ring and a ring of Laurent polynomials. On the Laurent factor, the involution is given by multiplicative inversion. If the involution were also to restrict to the polynomial factor, then the Tate cohomology of $Rep(P)$ would be equal to the Tate cohomology of that polynomial factor. However, in general, the involution does not restrict. One may therefore think of $Rep(P)$ as a kind of ‘twisted polynomial ring’. At least, this is the terminology we will use later (c.f. Section 4.2).

Throughout this section, the ground field may be arbitrary.
3.1 Representation rings of reductive groups

Before specializing to (Levi subgroups of) parabolic groups, we recall the general description of the representation ring of a split reductive group. So let $G$ be a split reductive group over a field, with split maximal torus $T$. We use the following notation:

- $X^* := X^*(T)$ the group of characters of $T$
- $X_* := X_*(T)$ the group of cocharacters $T$
- $\langle - , - \rangle$ the canonical pairing $X^* \times X_* \to \mathbb{Z}$
- $R \subset X^*$ the set of roots
- $R^\vee \subset X_*$ the set of coroots
- $R^+ \subset R$ a choice of positive roots
- $\Sigma \subset R^+$ the corresponding simple roots
- $\mathfrak{w}$ the Weyl group

3.1 Serre’s Theorem ([Ser68, Théorème 4]). For any split reductive group $G$ over a field, the character isomorphism $\text{Rep}(T) \to \mathbb{Z}[X^*]$ restricts to an isomorphism

$$\text{Rep}(G) \cong \mathbb{Z}[X^*]^\mathfrak{w}.$$  

Additively, the invariants under the Weyl group can be described as follows. Let

$$W := \{ \xi \in X^* \mid \langle \xi, \sigma^\vee \rangle \geq 0 \text{ for all } \sigma \in \Sigma \}$$

be the semigroup of dominant weights corresponding to our choice of simple roots $\Sigma$. It is a fundamental domain for the action of the Weyl group. Therefore

$$\mathbb{Z}[X^*]^W = \bigoplus_{\delta \in W} \mathbb{Z} \cdot S(\delta),$$

where $S(\delta)$ is the sum over the elements of the orbit of $\delta$ under the Weyl group: $S(\delta) = \sum_{\xi \in W \cdot \delta} e^\xi$.

As for the multiplicative structure, it is well-known that when $G$ is semisimple and simply connected, $\text{Rep}(G)$ is a polynomial ring. More generally, if $G$ is reductive with simply connected derived group $\mathcal{D}G$, the representation ring of $G$ may be identified with a product of the polynomial ring $\text{Rep}(\mathcal{D}G)$ and the ring of Laurent polynomials on the characters of $G$ ([SGA6, Exposé 0 App: RRR; Hod75, Proposition 11.1 (p. 81)]). However, this identification depends on certain choices. We provide a proof that will suit our later needs.

We decompose $X^*$ into a ‘toral part’ and a ‘semisimple part’. For the first part, we take the character group of $G$:

$$X^*(G) = (\Sigma^\vee)^\perp := \{ \xi \in X^* \mid \langle \xi, \sigma^\vee \rangle = 0 \text{ for all } \sigma \in \Sigma \}$$

The quotient $X^*/(\Sigma^\vee)^\perp$ can be identified with the character group of a maximal torus $T_{DG}$ of the derived group $\mathcal{D}G$ [Jan03, II.1.18]. Let $\Omega$ be an arbitrary\textsuperscript{5} complement of $(\Sigma^\vee)^\perp$ in $X^*$. Then the inclusion $i: T_{DG} \hookrightarrow T$ induces an isomorphism $i^*: \Omega \cong X^*_{DG}$ and we have decompositions:

$$X^* = (\Sigma^\vee)^\perp \oplus \Omega \cong X^*(G) \oplus X^*_{DG} \quad \text{and} \quad W = (\Sigma^\vee)^\perp \oplus (W \cap \Omega) \cong X^*(G) \oplus W_{DG}$$

When $\mathcal{D}G$ is simply connected, its set of dominant weights $W_{DG}$ is a free abelian semigroup, so the isomorphism above shows that $W$ decomposes as a direct sum of a free abelian group $(\Sigma^\vee)^\perp$ with trivial $W$-action and a free abelian semigroup $W \cap \Omega$.

\textsuperscript{5}We will see that when dealing with parabolic subgroups of simply connected semisimple groups, there is a natural choice for $\Omega$. See also Remark 3.3.
3.2 Theorem. Let $G$ be a split reductive group whose derived group $DG$ is simply connected. Let $X^* = X^*(G)\oplus\Omega$ be a decomposition as above. Choose a basis $\xi_1, \ldots, \xi_l$ of $X^*(G)$ and a basis $\omega_1, \ldots, \omega_r$ of the free semigroup $W\cap\Omega$. Then we have a ring isomorphism

$$Z[x_1^{\pm 1}, \ldots, x_l^{\pm 1}] \otimes Z[w_1, \ldots, w_r] \xrightarrow{=} Z[X^*]^W \cong \text{Rep}(G)$$

sending $x_i$ to $S(\xi_i) = e^{\xi_i}$ and $w_i$ to $S(\omega_i) = \sum_{\xi \in W, \omega_i} e^{\xi}$.

Proof. Recall that there exists a partial order on the dominant weights $W$ with the following properties [Ada69, 6.27, 6.36]:

- Only finitely many dominant weights are smaller than a fixed dominant weight.
- For arbitrary dominant weights $\delta$ and $\delta'$,
  
  $$S(\delta)S(\delta') = S(\delta + \delta') + (\text{smaller terms}).$$

Here, '$S(\delta) + (\text{smaller terms})$' is to be read as a short-hand for: there exist coefficients $a_\epsilon \in \mathbb{Z}$ such that

$$P = S(\delta) + \sum_{\epsilon \in W, \epsilon < \delta} a_\epsilon S(\epsilon).$$

Let $\Phi$ denote the ring homomorphism defined in the theorem.

For surjectivity, it suffices to show that, for any weight $\delta$ in $W$, the symmetric sum $S(\delta)$ has a preimage under $\Phi$. This may be checked by induction over the number of weights smaller than $\delta$. Indeed, let us write $\delta = \sum a_i \xi_i + \sum b_j \omega_j$ with coefficients $a_i \in \mathbb{Z}$ and $b_j \in \mathbb{N}$. By the second property of the ordering above,

$$\Phi(\prod x_i^{a_i} \otimes \prod w_j^{b_j}) = S(\delta) + (\text{smaller terms}).$$

By the inductive hypothesis, we may assume that all terms on the right-hand side apart from $S(\delta)$ are contained in the image of $\Phi$, so $S(\delta)$ itself must be contained therein.

For injectivity, take an arbitrary element

$$P = \sum_{a=(a_1, \ldots, a_l) \in \mathbb{Z}^l} c_{a,b} x_1^{a_1} \cdots x_l^{a_l} \cdot w_1^{b_1} \cdots w_r^{b_r}$$

and suppose that $\Phi(P) = 0$. We can write $\Phi(P)$ as

$$\Phi(P) = \sum_{a,b} c_{a,b} [S(\xi_{a,b}) + (\text{smaller terms})]$$

where $\xi_{a,b} := \sum a_i \xi_i + \sum b_j \omega_j$. The assumption that the $\omega_j$ form a basis and not just a generating set of $W\cap\Omega$ ensures that the $\xi_{a,b}$ and hence the $S(\xi_{a,b})$ are all distinct. Let $\mathcal{S}$ be the set of all pairs $(a,b)$ for which $c_{a,b}$ is non-zero. If $\mathcal{S}$ is non-empty, we may choose some $(a,b) \in \mathcal{S}$ such that $\xi_{a,b}$ is maximal in the sense that it is not smaller than any other $\xi_{a',b'}$ with $(a',b') \in \mathcal{S}$. Then $\Phi(P) = 0$ implies that $c_{a,b} = 0$—a contradiction. Thus, $\mathcal{S}$ must be empty and we find that $P = 0$. \[\square\]

3.3 Remark (Decomposition of $X^*_Q$). If we pass to $X^*_Q = X^* \otimes_{\mathbb{Z}} \mathbb{Q}$, we have a canonical decomposition

$$X^*_Q = (\Sigma\nu)^{\perp}_Q \oplus Q\Sigma.$$

However, $(\Sigma\nu)^{\perp}$ is, in general only a finite index subgroup of $X^*$. Geometrically, $Q\Sigma \cap X^*$ is the character group of a maximal torus of the semisimple quotient $G := G/RG$ and the isogeny $DG \to G$ exhibits $Q\Sigma \cap X^*$ as a finite index subgroup of $X^*_D$. 

16
3.2 Representation rings of parabolic subgroups

From now on, we assume that $G$ is semisimple and simply connected, so that $\Sigma^\vee$ is a basis for $X_*$. Let $\{\omega_\sigma \mid \sigma \in \Sigma\}$ be the fundamental weights of $G$, defined by

$$\langle \omega_\sigma, \nu^\vee \rangle = \delta_{\sigma \nu}$$

for $\sigma, \nu \in \Sigma$. Our assumptions ensure that the $\omega_\sigma$ form a basis for $X_*$ [Jan03, II.1.6].

The parabolic subgroups of $G$ are classified up to isomorphism by subsets $\Theta \subseteq \Sigma$. We write $P_\Theta$ for the standard parabolic subgroup corresponding to $\Theta$. Let $L_\Theta$ be its Levi subgroup and $U_\Theta$ its unipotent radical, so that $P_\Theta = L_\Theta \ltimes U_\Theta$.

The Levi subgroup $L_\Theta$ is the subgroup of $G$ generated by the maximal torus $T$ and the root subgroups corresponding to the roots in $R_\Theta := R \cap \mathbb{Z}\Theta$, while $U_\Theta$ is the subgroup generated by root subgroups corresponding to the roots in $(-R^+) - R_\Theta$ [Jan03, II.1.7–1.8]. For example, $L_\emptyset = T$ and $P_\emptyset$ is a Borel subgroup, while $L_\Sigma = P_\Sigma = G$.

3.4 Lemma. The projection $P_\Theta \twoheadrightarrow L_\Theta$ induces an isomorphism

$$\text{Rep}(P_\Theta) \cong \text{Rep}(L_\Theta).$$

Proof. This is a general fact for extensions of unipotent groups. For an arbitrary extension $1 \to U \to P \to L \to 1$, the projection $\pi$ induces a monomorphism $\text{Rep}(P) \hookrightarrow \text{Rep}(L)$ whose image is generated by those simple $P$-modules which have a non-zero $U$-fixed vector [Jan03, I.6.3]. When $U$ is unipotent, any non-zero representation has such a fixed vector. □

The Levi subgroup $L_\Theta$ is a split reductive group with maximal torus $T$, simple roots $\Theta$ and Weyl group the subgroup $W_\Theta \subseteq W$ generated by the reflections in the elements of $\Theta$ [Jan03, I.1.7]. The assumption that $G$ is simply connected ensures that $\mathcal{D}L_\Theta$ is also simply connected. We can therefore apply Theorem 3.2 to $L_\Theta$ and the decomposition

$$X^* = (\Theta^\vee)^\perp \oplus \Omega_\Theta,$$

where $\Omega_\Theta$ is the subgroup of $X^*$ generated by the fundamental weights $\{\omega_\vartheta \mid \vartheta \in \Theta\}$.

3.5 Corollary. Let $P_\Theta$ be a standard parabolic subgroup of a semisimple simply connected algebraic group $G$ with fundamental weights $\{\omega_\sigma \mid \sigma \in \Sigma\}$. Then we have a ring isomorphism

$$\mathbb{Z}[w_\Theta, x_\beta^{\perp \vartheta}] \mid \vartheta \in \Theta, \beta \in \Sigma - \Theta \xrightarrow{\cong} \mathbb{Z}[X^*]^{W_\Theta} \cong \text{Rep}(P_\Theta)$$

sending $w_\Theta$ to $S(e^{\omega_\vartheta})$ and $x_\beta$ to $S(e^{\omega_\vartheta}) = e^{\omega_\vartheta}$.

Proof. The fundamental weights $\{\omega_\beta \mid \beta \in \Sigma - \Theta\}$ form a basis of the character group $X^*(L_\Theta) = (\Theta^\vee)^\perp$, while the remaining fundamental weights $\{\omega_\vartheta \mid \vartheta \in \Theta\}$ form a basis of $\Omega_\Theta$. Moreover, the $\omega_\vartheta$ form a basis of the free semigroup $W_\Theta \cap \Omega_\Theta$, where $W_\Theta$ is the set of dominant weights of $L_\Theta$.

$$W_\Theta := \{\delta \in X^* \mid \langle \delta, \vartheta^\vee \rangle \geq 0 \text{ for all } \vartheta \in \Theta\}$$
3.3 Root data and fundamental weights

The relation between $L_\Theta$, its derived group $\mathcal{D}L_\Theta$, and its semisimple quotient $\bar{L}_\Theta := L_\Theta/R_{L_\Theta}$ will be central to all that follows. We will write $i$ and $p$ for the inclusion of $\mathcal{D}L_\Theta$ and the projection onto $\bar{L}_\Theta$:

$$\mathcal{D}L_\Theta \hookrightarrow L_\Theta \rightarrow \bar{L}_\Theta$$

Let $R_\Theta := R \cap Z\Theta$ and $R'_\Theta := R' \cap Z\Theta'$. The root data of $L_\Theta$, $\mathcal{D}L_\Theta$, and $\bar{L}_\Theta$ can be summarized as follows (c.f. [Jan03, II.1.18]):

$\mathcal{D}L_\Theta$: $(X^*/(\Theta^\vee)^\perp, X_\ast \cap \Theta^\vee, i^* R_\Theta, R'_\Theta)$

$L_\Theta$: $(X^*, X_\ast, R_\Theta, R'_\Theta)$

$\bar{L}_\Theta$: $(X^* \cap \Theta, X_\ast/\Theta^\perp, R_\Theta, p_\ast R'_\Theta)$

In the proof of Corollary 3.5, we used the decomposition $X^* = (\Theta^\vee)^\perp \oplus \Omega_\Theta$ for which $i^*$ restricts to an isomorphism $\Omega_\Theta \cong X^*_{\mathcal{D}L_\Theta}^\vee$. The fundamental weights of the simply connected group $\mathcal{D}L_\Theta$ are precisely the images of the fundamental weights $\omega_\delta \in \Omega_\Theta$:

$$i^* \omega_\delta = \omega_{i^* \delta}$$

As in Remark 3.3, we also have a rational decomposition

$$X_\ast^\perp = (\Theta^\vee)^\perp \oplus \Theta$$

The subspace $\Theta \subset X_\ast^\perp$ does not in general contain any fundamental weights of $G$. Rather, the fundamental weights $\bar{\omega}_\delta$ of $\bar{L}_\Theta$ are the components of the weights $\omega_\delta$ in the direction of $\Theta$:

$$\omega_\delta = \pi^+(\omega_\delta) + \bar{\omega}_\delta$$

where $\pi^+: (\Theta^\vee)^\perp \oplus \Theta \to (\Theta^\vee)^\perp$ denotes the projection away from $\Theta$.

All three groups $L_\Theta$, $\mathcal{D}L_\Theta$, and $\bar{L}_\Theta$ have the same Weyl group $W_\Theta$. The projection $i^*$ and the inclusion $p_\ast$ are equivariant with respect to its action.

3.4 Involutions on the weight lattice

We can analyse the involution on $\text{Rep}(P_\Theta)$ induced by the duality on representations by considering the inclusion $\text{Rep}(R_\Theta) \hookrightarrow \text{Rep}(T) = \mathbb{Z}[X^*]$. On $X^*$, the duality corresponds to multiplication by $-1$, so the induced involution $*$ on $\mathbb{Z}[X^*]$ is given by

$$(e^\xi)^* := e^{-\xi}.$$ 

To describe how this involution acts on $S(\delta)$ for a dominant weight $\delta \in W_\Theta$, we introduce a second involution $\circ$ on $X^*$ that restricts to $W_\Theta$.

3.6 Definition. Let $w_0$ be the longest element of the Weyl group $W_\Theta$. For any $\xi \in X^*$, we define

$$\xi^\circ := -w_0 \cdot \xi.$$ 

The involution $\circ$ restricts to $W_\Theta$ since $w_0$ sends $W_\Theta$ to $-W_\Theta$ [Jan03, II.1.5]. As $S(\xi)^* = S(-\xi) = S(-w \cdot \xi)$ for arbitrary $\xi \in X^*$ and $w \in W_\Theta$, we obtain:

3.7 Lemma. The $*\cdot$-dual of $S(\delta) \in \mathbb{Z}[\Lambda]^{W_\Theta}$ is given by $S(\delta)^* = S(\delta^\circ)$.
The lemma shows that the duality on $\mathbb{Z}[A]^{\omega_0}$ is determined by the action of an element $w_0 \in W_\Theta$. We therefore take a closer look at the interaction of the Weyl group with the decomposition $X^* = (\Theta^\vee)^\perp \oplus \Omega_\Theta$. On $(\Theta^\vee)^\perp$, the action of $W_\Theta$ is trivial. But the action does not restrict to $\Omega_\Theta$. Instead, we can define an action on $\Omega_\Theta$ by lifting the action on $X^*_D L_\Theta$ via the isomorphism $i^*: \Omega_\Theta \cong X^*_D L_\Theta$:

### 3.8 Definition. For $w \in W_\Theta$ and $\omega \in \Omega_\Theta$, we define $w\#\omega$ and $\omega^{\#}$ to be the unique elements of $\Omega_\Theta$ satisfying:

$$i^* (w\#\omega) = i^* (w.\omega) \quad (= w.i^*\omega)$$

$$i^* (\omega^{\#}) = i^* (\omega^\circ) \quad (= i^*(\omega)^\circ)$$

Evidently, $\omega^{\#} = -w_0\#\omega$, and $\#$ defines an involution on $\Omega_\Theta$ that restricts to $W_\Theta \cap \Omega_\Theta$.

Now consider the rational decomposition $X^*_\Theta = (\Theta^\vee)^\perp \oplus \mathcal{Q}\Theta$. Unlike the integral decomposition above, this decomposition is equivariant: the action of $W_\Theta$ restricts to both factors. Recall that $\pi^+: X^*_\Theta \to (\Theta^\vee)^\perp$ denotes the projection away from $\mathcal{Q}\Theta$.

### 3.9 Lemma. For any $w \in W_\Theta$ and any $\omega \in \Omega_\Theta$, we have

$$w\#\omega = w.\omega - \pi^+(\omega) + \pi^+(w\#\omega). \quad (9)$$

**Proof.** As the decomposition (7) is equivariant, we have $\pi^+(\omega) = \pi^+(w.\omega)$. We can thus rewrite eq. (9) as $w\#\omega - \pi^+(w\#\omega) = w.\omega - \pi^+(w.\omega)$, with both sides in $\mathcal{Q}\Theta$. It suffices to check this equation after applying $i^*: X^* \to X^*_D L_\Theta$ since $i^*$ induces an isomorphism from $\mathcal{Q}\Theta$ to $X^*_D L_\Theta, Q$. As $i^*\pi^+ = 0$, we are left with the defining equation of $w\#\omega$. \qed

### 3.10 Corollary. The $\varrho$-dual of an element $\omega \in \Omega_\Theta$ can be written as

$$\omega^\varrho = \omega^{\#} + \tau(\omega), \quad (10)$$

where $\tau(\omega) := -\pi^+(\omega) - \pi^+(\omega^{\#}) \in (\Theta^\vee)^\perp$. \qed

Let us reformulate eq. (10) in terms of the fundamental weights. Consider first the involution $\varrho = -w_0$ on the lattice $X^*_D L_\Theta$ of the semisimple group $D L_\Theta$. It restricts to the set of positive roots [Jan03, II.1.5] and hence to the simple roots $i^*\Theta$. It follows that $\varrho$ also restricts to an involution on the set of fundamental weights $\{\omega_{i^*\vartheta} \mid \vartheta \in \Theta\}$, such that

$$(\omega_{i^*\vartheta})^\varrho = \omega_{i^*\varrho^\vartheta}. \quad (11)$$

Now consider the action of $-w_0$ on $X^*$. It also restricts to an involution $\vartheta \mapsto \varrho^\vartheta$ on the simple roots $\Theta$, identical under $i^*$ to the involution on $i^*\Theta$. But it does not restrict to an involution of the fundamental weights $\omega_{\vartheta}$. Rather, we have:

### 3.11 Lemma. For any $\vartheta \in \Theta$, $\omega_{\vartheta}^{\#} = \omega_{\varrho^\vartheta}$.  

**Proof.** Clearly $\omega_{\varrho^\vartheta} \in \Omega_\Theta$. So we only need show that $\omega_{\varrho^\vartheta}$ satisfies the defining property of $\omega_{\vartheta}^{\#}$. This follows from eq. (6) and (11): $i^*(\omega_{\varrho^\vartheta}) = (\omega_{i^*\vartheta})^\varrho = (\omega_{i^*\varrho^\vartheta})^\varrho = (i^*\omega_{\vartheta})^\varrho$, as required. \qed

### 3.12 Corollary. The $\varrho$-duals of fundamental weights $\omega_{\vartheta}$ with $\vartheta \in \Theta$ and $\omega_{\beta}$ with $\beta \in \Sigma - \Theta$ are given by

$$\omega_{\varrho}^\vartheta = -\omega_{\vartheta}$$

$$\omega_{\varrho}^\beta = \omega_{\varrho^\beta} + \tau(\omega_{\vartheta}),$$

where $\tau(\omega_{\vartheta}) = -\pi^+(\omega_{\vartheta}) - \pi^+(\omega_{\varrho^\vartheta})$. \qed
3.5 The involution on the representation ring

We can now indicate the general form of the duality on \( \text{Rep}(P_\Theta) \). Let us write the twists \( \tau(\omega) \) as vectors in the basis \( \{ \omega_\beta | \beta \in \Sigma - \Theta \} \) of \( (\Theta^\vee)^\perp \):

\[
\tau(\omega) = \sum_{\beta \in \Sigma - \Theta} m^0_\beta \omega_\beta \quad \in (\Theta^\vee)^\perp.
\]

3.13 Corollary. Under the isomorphism

\[
\mathbb{Z}[w_\vartheta, x_\beta^{\pm 1} | \vartheta \in \Theta, \beta \in \Sigma - \Theta] \cong \text{Rep}(P_\Theta)
\]

of Corollary 3.5, the involution on \( \text{Rep}(P_\Theta) \) that sends a representation to its dual representation corresponds to the duality \( \ast \) given by:

\[
w_\vartheta^\ast = w_\vartheta \cdot \prod_{\beta} x_\beta^{m_\vartheta_\beta}
\]

\[
x_\beta^\ast = x_\beta^{-1}
\]

In the following, we will sometimes simply write \( w_\vartheta^\ast = w_\vartheta \cdot x^{m_\vartheta} \), i.e. we use the conventions \( m_\vartheta := (m_\vartheta_\beta)_{\beta \in \Sigma - \Theta} \) and \( x^{m_\vartheta} := \prod_{\beta} x_\beta^{m_\vartheta_\beta} \).

Proof. Recall that under the given isomorphism, \( w_\vartheta \) corresponds to \( S(\omega_\vartheta) \) and \( x_\beta \) corresponds to \( S(\omega_\beta) = e^{\omega_\beta} \). By Lemma 3.7 and Corollary 3.12 we have \( S(\omega_\vartheta)^\ast = S(\omega_\vartheta) = S(\omega_\vartheta + \tau(\omega_\vartheta)) \). In general, we have the formula \( S(\delta + \delta') = S(\delta)S(\delta') + \text{(smaller terms)} \). However, when the Weyl group acts trivially on one of \( \delta, \delta' \), there are no smaller terms and we simply have \( S(\delta + \delta') = S(\delta)S(\delta') \). Thus, given that \( W_\Theta \) acts trivially on \( (\Theta^\vee)^\perp \), we obtain

\[
S(\omega_\vartheta + \tau(\omega_\vartheta)) = S(\omega_\vartheta) \cdot S(\tau(\omega_\vartheta))
\]

\[
= S(\omega_\vartheta) \cdot S(\sum_{\beta \in \Sigma - \Theta} m^0_\beta \omega_\beta)
\]

\[
= S(\omega_\vartheta) \cdot \prod_{\beta} S(\omega_\beta)^{m^0_\beta}.
\]

4 Tate cohomology

This section contains the heart of our computations. After introducing a notion of twisted Tate cohomology in Section 4.1, in Section 4.2 we compute this cohomology for any ‘twisted polynomial ring’, a ring with involution that has the same formal description as the representation ring of a parabolic subgroup (c.f. Corollary 3.13). In particular, we will see that the twisted Tate cohomology groups are either zero or isomorphic to the untwisted ones. In Section 4.3, this dichotomy is generalized to the Tate cohomology of certain quotients of twisted polynomial rings. The result applies in particular to the K-ring of a flag variety (c.f. Theorem 5.2).

4.1 Twisted Tate cohomology

We use the same terminology for rings with involution as in [Zib12]. In particular, a \( \ast \)-ring is a commutative unital ring equipped with an involution \( \ast \) which is a ring isomorphism, and a \( \ast \)-ideal in a \( \ast \)-ring \( A \) is an ideal preserved by \( \ast \). We say that a \( \ast \)-ideal \( \mathfrak{a} \subset A \) is generated by certain elements \( a_1, \ldots, a_n \) and write

\[
\mathfrak{a} = (a_1, \ldots, a_n)
\]
if $a$ is generated as an ideal in the usual sense by the elements $a_1, a_1^*, \ldots, a_n, a_n^*$.

More generally, an $(A, \ast)$-module is an $A$-module $M$ together with an additive involution $\ast$ that satisfies $(am)^\ast = a^*m^*$ for all $a \in A$ and $m \in M$.

An element $x \in M$ is $\ast$-self-dual if $x = x^*$ and $\ast$-anti-self-dual if $x^* = -x^*$.

The Tate cohomology groups of $(M, \ast)$ are:

$$h^+(M, \ast) := \frac{\ker(id - \ast)}{\text{im}(id + \ast)}$$

$$h^-(M, \ast) := \frac{\ker(id + \ast)}{\text{im}(id - \ast)}$$

We write $h^*(M, \ast)$ for the $\mathbb{Z}/2$-graded abelian group $h^+(M, \ast) \oplus h^-(M, \ast)$.

Given an $(A, \ast)$-module $M$ and a unit $l \in A^\times$ such that $l^* = l^{-1}$, we define the $l$-twisted involution $\ast_l$ on $M$ by

$$m^\ast_l := m^* l.$$ 

4.1 Lemma. Let $(A, \ast)$ be a $\ast$-ring, and let $l_1, l_2 \in A^\times$ be units such that $l_i^* = l_i^{-1}$. Then for any $(A, \ast)$-module $(M, \ast)$, the $A$-module structure map $A \otimes M \to M$ descends to a homomorphism of $\mathbb{Z}/2$-graded groups

$$h^*(A, \ast_{l_1}) \otimes h^*(M, \ast_{l_2}) \to h^*(M, \ast_{l_1 l_2}).$$

In particular, $h^*(A, \ast)$ is a $\mathbb{Z}/2$-graded ring, and $h^*(M, \ast_{l_1})$ is a graded $h^*(A, \ast)$-module.

The rings and modules we will be considering in the following will usually come equipped with some ‘default’ involution $\ast$. We then simply write

$$h^*(A) := h^*(A, \ast)$$

$$h^*(M) := h^*(M, \ast)$$

$$h^*(M, l) := h^*(M, \ast_l)$$

and refer to $h^*(M, l)$ as the $l$-twisted Tate cohomology of $M$.

4.2 Tate cohomology of twisted polynomial rings

We use the term twisted polynomial ring to refer to a $\ast$-ring $(A, \ast)$ of the following form:

- As a ring, $A$ is isomorphic to a tensor product of a polynomial ring and a ring of Laurent polynomials

$$A \cong \mathbb{Z} [\gamma_i, \gamma_i', \mu_j, x_k^\pm 1 | i \in I, j \in J, k \in K]$$

- This isomorphism can be chosen such that the duality on $A$ has the following form:

$$\gamma_i^* = \gamma_i' \cdot x^{c_i}$$

$$\mu_j^* = \mu_j \cdot x^{m_j}$$

$$x_k^* = x_k^{-1}$$

for certain $c_i \in \mathbb{Z}^{[K]}$ and $m_j \in \mathbb{Z}^{[K]}$.

Here and in the following, we use a bold-face letter $c$ to denote a tuple with entries $c_k$, and

$$x^m := \prod_k x^k.$$

We think of the $\mu_j$ as ‘self-dual’ generators and of the $\gamma_i$ as ‘non-self-dual’ generators, except that they carry ‘individual twists’ $m_j'$. By Corollary 3.13,
the representation ring of any parabolic subgroup of a simply connected split
semisimple algebraic group is a twisted polynomial ring in our sense: we only
need to take
\[ \mu_{\vartheta} := w_{\vartheta} \quad \text{for each } \vartheta \text{ with } \vartheta^\circ = \vartheta \quad \text{(so } m^\vartheta = m^\vartheta) \]
\[ \gamma_{\vartheta} := w_{\vartheta} \quad \gamma'_{\vartheta} := w_{\vartheta^\circ} \quad \text{for each pair } (\vartheta, \vartheta^\circ) \text{ with } \vartheta^\circ \neq \vartheta \quad \text{(so } c^\vartheta = m^\vartheta) \]

Our aim is to describe \( h^*(A, x^t) \) for any twisted polynomial ring \((A, *)\) as above
and any twist \( x^t \) \((t \in \mathbb{Z}[^K])\). As we will see, these groups essentially depend
only on their reductions modulo two \( \bar{m}^t \), \( t \in (\mathbb{Z}/2)^[^K] \). First, we have a
simple criterion when \( h^*(A, x^t) \) vanishes:

**4.2 Proposition.** The twisted Tate cohomology module \( h^*(A, x^t) \) is non-zero
if and only if the inhomogeneous linear system of equations

\[ \text{either } \begin{cases} m \cdot \bar{j} = \bar{t} \\ \end{cases} \quad \text{(I)} \]

has some solution \( \bar{j} \in (\mathbb{Z}/2)^[^J] \). Note that any vector \( \bar{j} \in (\mathbb{Z}/2)^[^J] \)
can be lifted to a tuple with coefficients in \( \mathbb{N}_0 \), and that there is a unique lift with coefficients
in \( \{0, 1\} \). We call the lift \( \bar{j} \in \{0, 1\}[^J] \) minimal.

**4.3 Proposition.** Let \( \mathcal{S} \subset (\mathbb{Z}/2)^[^J] \) be a basis of the space of solutions of the
homogeneous part of \((\mathbb{I}), \) and let \( \mathcal{S} \subset \{0, 1\}[^J] \) be the set of minimal lifts of
these basis elements. The untwisted Tate cohomology ring of \( A \) is concentrated
in degree zero and can be written as

\[ h^*(A) = \mathbb{Z}/2 [\gamma_i^\sigma | i \in I] \oplus \mathbb{Z}/2 [\nu_j, \sigma_j | \bar{j} \in \mathcal{S}, j \in J] \]

with \( \nu_j := \mu_j x^j \bar{m}^j \) and \( \sigma_j := \mu_j^2 x^j m^j \).

**4.4 Proposition.** If \( h^*(A, x^t) \) is non-zero, there is an element \( \zeta_t \in h^*(A, x^t) \)
such that multiplication with \( \zeta_t \) induces an isomorphism

\[ h^*(A) \xrightarrow{\zeta_t} h^*(A, x^t) \]

Moreover, if both \( h^*(A, x^{t_1}) \) and \( h^*(A, x^{t_2}) \) are non-zero, then so is
\( h^*(A, x^{t_1+2t_i}) \) and we may take \( \zeta_{t_1+t_2} = \zeta_{t_1} \cdot \zeta_{t_2} \).

**Proof of Propositions 4.2 and 4.3.** Let \( *_t \) denote the \( x^t \)-twisted involution on
\( A \). As a first reduction, we may factorize \((A, *_t)\) into a tensor product of
\((A, *)\)-modules:

\[ A = \mathbb{Z} [\gamma_i, \gamma_i^* | i \in I] \otimes \mathbb{Z} [\mu_j, x_j^k | j \in J, k \in K] \]

Since both factors are free \( \mathbb{Z} \)-modules, we have a corresponding factorization
of the Tate cohomology modules:

\[ h^*(A, x^t) = \mathbb{Z}/2 [\gamma_i^\sigma | i \in I] \otimes h^*(A', x^t) \]

with \( A' = \mathbb{Z} [\mu_j, x_j^{k+1} | j \in J, k \in K] \).
In order to compute the Tate cohomology of $A'$, we observe that the set of monomials
\[ \{ \mu^j x^k \mid j \in \mathbb{N}_0^{[J]}, k \in \mathbb{Z}^{[K]} \} \]
forms a basis of $A'$ over $\mathbb{Z}$ which is taken into itself by the involution $^*$. This implies that $h^+(A')$ is a $\mathbb{Z}/2$-module on those basis elements fixed under the involution, while $h^-(A') = 0$.

So let $h := \mu^j x^k$ be an arbitrary basis element. We can easily express the fixed-point condition on $h$ as a linear system of equations in $(j, k) \in \mathbb{N}_0^{[J]} \times \mathbb{Z}^{[K]}$:
\[ h^* = h \iff Mj - 2k = -t \] (I)

Proposition 4.2 follows from the fact that the linear system (I) has a solution if and only if its reduction modulo two (I) has a solution: given a solution $\bar{j}_0 \in (\mathbb{Z}/2)^{[J]}$ of (I), we obtain a solution $(j_0, k_0)$ of (I) by taking $j_0$ to be some lift of $\bar{j}_0$ and setting $k_0 := \frac{1}{2}(Mj_0 + t)$.

Now consider the homogeneous part of the system and its reduction modulo two:
\[ Mj - 2k = 0 \] (H)
\[ \bar{Mj} = 0 \] (I)

Again, the space of solutions of (H) is determined by the space of solutions of (I): For any any solution $(j_h, k_h)$ of (H), we have $k_h = \frac{1}{2}Mj_h$ and we can write $j_h$ as $j_h = j_m + 2r$ for some $j_m$ with coefficients in $\{0, 1\}$ and some $r$ with coefficients in $\mathbb{N}_0$. Then $j_m$ is a solution of (I). Conversely, any solution $j_m$ of (I) and any $r \in \mathbb{N}_0^{[J]}$ determine a solution
\[ \left( \begin{array}{c} j_h \\ k_h \end{array} \right) = \left( \begin{array}{c} j_m \\ \frac{1}{2}Mj_m \end{array} \right) + \left( \begin{array}{c} 2r \\ Mr \end{array} \right) \] (12)

of (I).

We may view the space of solutions of (H) as a sub-semigroup of $\mathbb{N}_0^{[J]} \times \mathbb{Z}^{[K]}$. In order to describe generators, we choose a basis $\bar{S}$ of the space of solutions of (I) and let $S$ be the set of minimal lifts of these basis vectors, as above. Let $e_j$ with $j \in J$ denote the standard basis vectors in $\mathbb{N}_0^{[J]}$. Then it follows from (12) that a set of generators of the semigroup of solutions of (I) is given by
\[ \left\{ \left( \begin{array}{c} j \\ \frac{1}{2}Mj \end{array} \right), \left( \begin{array}{c} 2e_j \\ m^j \end{array} \right) \mid j \in S, j \in J \right\} \]

These generators correspond to the algebra generators $\nu_j$ and $\sigma_j$ of $h^+(A)$ appearing in Proposition 4.3.

It remains to determine the relations between these generators. Suppose
\[ \sum_{j \in \mathcal{S}} a_j \left( \begin{array}{c} j \\ \frac{1}{2}Mj \end{array} \right) + \sum_{j \in J} b_j \left( \begin{array}{c} 2e_j \\ m^j \end{array} \right) = 0 \]

for certain $a_j, b_j \in \mathbb{Z}$. Since the vectors $\bar{j} \in \mathcal{S}$ are linearly independent over $\mathbb{Z}/2$, all coefficients $a_j$ must be even. Conversely, for any choice of even coefficients $a_j$, we obtain a relation by setting
\[ b_j := -\left[ \sum_{\bar{j} \in \mathcal{S}} a_{\bar{j}} \right] \]
where \([v]_j\) denotes the \(j\)th component of a tuple \(v\). It follows that the space of relations is generated by the unique relations with \(a_j\) equal to 2 for just one \(j \in S\) and equal to 0 for all others, i.e. by the relations

\[
\left\{ 2 \left( \frac{j}{2}\right) M_j \right\} = \sum_{j \in J} \left( 2 e_j \right) \left( \frac{m^j}{m} \right) \left| j \in S \right.
\]

In \(h^*(A)\), these relations correspond to the relations \(\nu^j = \sigma^j\).

\(\Box\)

**Proof of Proposition 4.4.** A general solution \((j_i, k_i)\) of (I) will be of the form

\[
\left( j_i \right) = \left( j_0 \right) + \left( j_h \right),
\]

where \((j_0, k_0)\) is some solution of (I) with coefficients in \(\{0, 1\}\) and \((j_h, k_h)\) is a solution of the homogeneous system (H). Thus, we can take

\[
\zeta_t := \mu^{j_0} x^{k_0} = \mu^{j_0} x^{1/2} (M_{j_0} + t).
\]

The second claim of Proposition 4.4 also follows from this explicit description of \(\zeta_t\).

\(\Box\)

### 4.3 Tate cohomology of quotients

In this section, we show how to generalize the results of the previous section to certain quotients of twisted polynomial rings. More precisely, we show:

**4.5 Proposition.** Let \((A, *)\) be a \(*\)-ring, and let \(l \in A^*\) be a unit such that \(l^* = l^{-1}\). If \(\zeta \in A\) is \(*_1\)-self-dual and induces an isomorphism

\[
h^*(A) \xrightarrow{\sim} h^*(A, *_1),
\]

then multiplication by \(\zeta\) also induces an isomorphism

\[
h^*(A/\mathfrak{a}) \xrightarrow{\sim} h^*(A/\mathfrak{a}, *_1),
\]

for any \(*\)-ideal \(\mathfrak{a} \subset A\) that can be generated by elements \(\lambda_1, \ldots, \lambda_k\) and \(*\)-self-dual elements \(\mu_1, \ldots, \mu_l\) such that \(\lambda_1, \lambda_1^*, \ldots, \lambda_k, \lambda_k^*, \mu_1, \ldots, \mu_l\) is a regular sequence in \(A\).

We divide the proof into two lemmas.

**4.6 Lemma.** Let \((A, *)\) be a \(*\)-ring, and let \(l \in A^*\) be a unit such that \(l^* = l^{-1}\).

- If \(\mu \in A\) is a \(*\)-self-dual element that is not a zero divisor, then multiplication by \(\mu\) induces a graded isomorphism

\[
h^*(A, *_1) \xrightarrow{\sim} h^*((\mu), *_1)
\]

- If \((\lambda, \lambda^*)\) is a regular sequence in \(A\), then multiplication by the product \(\lambda \lambda^*\) induces a graded isomorphism

\[
h^*(A, *_1) \xrightarrow{\sim} h^*((\lambda, \lambda^*), *_1)
\]

**Proof.** This is a mild generalization of one half of Proposition 4.1 of [Zib12]. It can be proved in exactly the same way. (The other half of the proposition can also be generalized, but it is not used in the following.)

\(\Box\)
4.7 Lemma. Let \((A, \ast)\) be a \(*\)-ring, and let \(l \in A^\times\) be a unit such that \(l^\ast = l^{-1}\). Suppose there is an \(*\)-self-dual element \(\zeta \in A\) such that multiplication with \(\zeta\) induces an isomorphism
\[
h^\ast(A) \xrightarrow{\zeta} h^\ast(A, \ast_l).
\]
Then multiplication with \(\zeta\) also induces isomorphisms
\[
\begin{align*}
h^\ast(A/\mu) & \xrightarrow{\zeta} h^\ast(A/\mu, \ast_l) \\
h^\ast(A/(\lambda, \lambda^\ast)) & \xrightarrow{\zeta} h^\ast(A/(\lambda, \lambda^\ast), \ast_l)
\end{align*}
\]
for any \(*\)-self-dual non-zero divisor \(\mu\) of \(A\) and any regular sequence \((\lambda, \lambda^\ast)\) in \(A\).

Proof. As \(\zeta\) is \(*\)-self-dual, multiplication by \(\zeta\) induces a \(*\)-morphism \((M, \ast) \to (M, \ast_l)\) for any \((A, \ast)\)-module \((M, \ast)\). Given a regular sequence \((\lambda, \lambda^\ast)\) as in the lemma, consider the following commutative square of \((A, \ast)\)-modules and the induced commutative square of \(h^\ast(A)\)-modules:
\[
\begin{array}{ccc}
(A, \ast) & \xrightarrow{\lambda \lambda^\ast} & (\lambda, \lambda^\ast) \\
\zeta & \downarrow & \downarrow \\
(A, \ast_l) & \xrightarrow{\lambda \lambda^\ast} & (\lambda, \lambda^\ast, \ast_l)
\end{array}
\quad
\begin{array}{ccc}
h^\ast(A) & \xrightarrow{\lambda \lambda^\ast} & h^\ast(\lambda, \lambda^\ast) \\
\zeta & \downarrow & \downarrow \\
h^\ast(A, \ast_l) & \xrightarrow{\lambda \lambda^\ast} & h^\ast(\lambda, \lambda^\ast, \ast_l)
\end{array}
\]
In the right-hand square, the horizontal morphisms are isomorphisms by Lemma 4.6 and the vertical morphism on the left is an isomorphism by assumption. So \(\zeta: h^\ast((\lambda, \lambda^\ast)) \to h^\ast((\lambda, \lambda^\ast), \ast_l)\) is also an isomorphism. To obtain the analogous claim for the quotient \(A/(\lambda, \lambda^\ast)\), we consider the long exact Tate cohomology sequences associated with the obvious two short exact sequences of \((A, \ast)\)-modules:
\[
\begin{align*}
0 & \to ((\lambda, \lambda^\ast), \ast) \to (A, \ast) \to (A/(\lambda, \lambda^\ast), \ast) \to 0 \\
0 & \to ((\lambda, \lambda^\ast), \ast_l) \to (A, \ast_l) \to (A/(\lambda, \lambda^\ast), \ast_l) \to 0
\end{align*}
\]
Multiplication by \(\zeta\) induces an isomorphisms on two out of three terms of these long exact sequences, so by the Five Lemma it also induces an isomorphism on the remaining term. The proof for the case of a \(*\)-self-dual non-zero divisor \(\mu\) works in the same way.

Proof of Proposition 4.5. Proposition 4.5 now follows by induction over the number of generators of \(\mathfrak{a}\). Indeed, suppose the claim holds for the ideal \(\mathfrak{a}' \subset \mathfrak{a}\) generated by all but one of the given generators of \(\mathfrak{a}\), so that \(\zeta\) induces an isomorphism \(h^\ast(A/\mathfrak{a}') \cong h^\ast(A/\mathfrak{a}', \ast_l)\). The assumptions ensure that the remaining generator of \(\mathfrak{a}\) will either be a \(*\)-self-dual element \(\mu\) which is not a zero-divisor in \(A/\mathfrak{a}'\) or an element \(\lambda\) such that \((\lambda, \lambda^\ast)\) is a regular sequence in \(A/\mathfrak{a}'\). Thus, we can conclude using Lemma 4.7.
5 Translation

5.1 The proofs

The considerations above easily imply the following two precursors of Structure Theorem 1.1:

5.1 Proposition. Let $P$ be a parabolic subgroup of a semisimple simply connected algebraic group over a field, and let $\text{Rep}(P)$ be its representation ring equipped with the usual involution induced by duality. Let $\omega \in \text{Rep}(P)^{*}$ be a character of $P$. If the twisted total Tate cohomology group $h^{*}(\text{Rep}(P), \omega)$ is non-zero, then there exists an element $\zeta_{\omega}$ in $h^{*}(\text{Rep}(P), \omega)$ such that multiplication by $\zeta_{\omega}$ induces an isomorphism of $\mathbb{Z}/2$-graded modules

$$h^{*}(\text{Rep}(P)) \xrightarrow{\sim} h^{*}(\text{Rep}(P), \omega).$$

Moreover, if both $h^{*}(\text{Rep}(P), \omega_{1})$ and $h^{*}(\text{Rep}(P), \omega_{2})$ are non-zero for characters $\omega_{1}$ and $\omega_{2}$ of $P$, then so is $h^{*}(\text{Rep}(P), \omega_{1} \otimes \omega_{2})$ and we may choose $\zeta_{\omega_{1} \otimes \omega_{2}} = \zeta_{\omega_{1}} \cdot \zeta_{\omega_{2}}$.

Proof. This is a translation of Propositions 4.3 and 4.4. Indeed, by Corollaries 3.5 and 3.13 we have an isomorphism

$$\text{Rep}(P) \cong \mathbb{Z}[w_{\beta}, x_{\beta}^{\pm 1} \mid \vartheta \in \Theta, \beta \in \Sigma - \Theta]$$

(13)

that identifies $\text{Rep}(P)$ with a twisted polynomial ring in the sense of Section 4.2. Under this isomorphism, the character $\omega_{\beta}$ of $P$ ($\beta \in \Sigma - \Theta$) corresponds to the invertible element $x_{\beta}$, so a general character $\omega^{t} = \otimes_{\beta \in \Sigma - \Theta} \omega_{\beta}^{t}$ corresponds to a product $x^{t} = \prod_{\beta \in \Sigma - \Theta} x_{\beta}^{t}$.

5.2 Theorem. Let $G$ be a split semisimple simply connected algebraic group over a field, let $P \subset G$ be a parabolic subgroup, and let $\mathcal{L}$ be a line bundle over $G/P$. If the twisted total Tate cohomology group $h^{*}(G/P, \mathcal{L})$ is non-zero, then there exists an element $\zeta_{\mathcal{L}}$ in $h^{*}(G/P, \mathcal{L})$ such that multiplication by $\zeta_{\mathcal{L}}$ induces an isomorphism of $\mathbb{Z}/2$-graded modules

$$h^{*}(G/P) \xrightarrow{\sim} h^{*}(G/P, \mathcal{L}).$$

Moreover, if both $h^{*}(G/P, \mathcal{L}_{1})$ and $h^{*}(G/P, \mathcal{L}_{2})$ are non-zero for line bundles $\mathcal{L}_{1}$ and $\mathcal{L}_{2}$, then so is $h^{*}(G/P, \mathcal{L}_{1} \otimes \mathcal{L}_{2})$ and we may choose $\zeta_{\mathcal{L}_{1} \otimes \mathcal{L}_{2}} = \zeta_{\mathcal{L}_{1}} \cdot \zeta_{\mathcal{L}_{2}}$.

Proof. We apply Proposition 4.5 to $A := \text{Rep}(P)$ and the ideal $\mathfrak{a}$ of Panin’s Theorem 2.7. The required assumptions on $A$ are satisfied by the previous proposition. To check that $\mathfrak{a}$ also satisfies the required assumptions, we recall that the representation ring of $G$ can be written as a polynomial ring on generators $\lambda_{1}, \lambda_{1}^{\ast}, \ldots, \lambda_{k}, \lambda_{k}^{\ast}, \mu_{1}, \ldots, \mu_{l}$ with $\mu_{1}, \ldots, \mu_{l}$ self-dual (e.g. take $\Theta = \Sigma$ in Corollary 3.13). The ideal $\mathfrak{a}$ is generated by the corresponding rank zero classes $\lambda_{i} - \text{rk}(\lambda_{i})$, \ldots in $\text{Rep}(P)$. These classes form a regular sequence in $\text{Rep}(G)$. By Steinberg’s Theorem 2.8, $\text{Rep}(P)$ is free over $\text{Rep}(G)$, so their images in $\text{Rep}(P)$ likewise form a regular sequence.

Structure Theorem 1.1 is now an immediate corollary of Theorem 2.3. Similarly, Vanishing Theorem 1.2 is a consequence of:

5.3 Theorem. Let $G/P$ and $\mathcal{L} \in \text{Pic}(G/P)$ be as above. Let $m^{\vartheta}$ be the twist vectors describing the duality on $\text{Rep}(P)$ as in Corollary 3.13. View the twist vectors as elements of $\text{Pic}(G/P)$ via the identification of the Picard group with the character group $X^{*}(P)$ as in (4). Then $h^{*}(G/P, \mathcal{L})$ is non-zero if and only if the reduction of $\mathcal{L}$ modulo two is a linear combination of the reductions $m^\vartheta$ of those twist vectors with $\vartheta = \vartheta^\circ$.
Proof. Again, this is a direct translation of Proposition 4.2.

5.2 The twists

In this section we describe the twists \( m^\vartheta \) of Corollary 3.13 explicitly. The result in Corollary 5.5 will refer to a list of values that we have organized in Figure 2 in terms of Dynkin diagrams. Let us recall our graphical conventions and explain our notation.

- Associated with our semisimple group \( G \), we have an ‘ambient root system’ \( \mathcal{R} \) with root space \( X_\mathbb{Q}^* \) and simple roots \( \Sigma \). The corresponding ‘ambient Dynkin diagram’ has a node for each simple root \( \sigma \in \Sigma \). We draw this Dynkin diagram using blank circles, e.g.:

  ![Dynkin diagram](image)

We write \( C_{\sigma \nu} = \langle \sigma, \nu^\vee \rangle \) for the coefficients of the Cartan matrix of \( \mathcal{R} \). These can be read off directly from the Dynkin diagram using Figure 4 (ignoring the colours for the moment).

- The root system \( \mathcal{R}_\Theta \) associated with \( L_\Theta \) or \( \bar{L}_\Theta \) has root space \( \mathbb{Q}_\Theta \subset X_\mathbb{Q}^* \) and simple roots \( \Theta \). The corresponding Dynkin diagram has a node for each root \( \vartheta \in \Theta \). We will indicate this Dynkin diagram by filling the corresponding nodes of the ambient diagram, e.g.:

  ![Filled Dynkin diagram](image)

The coefficients of the Cartan matrix of \( \mathcal{R}_\Theta \) and its inverse matrix will be denoted by \( \check{C}_{\vartheta \nu} \) and \( \check{C}^{\vartheta \nu} \), respectively.\(^6\) For irreducible \( \mathcal{R}_\Theta \), the values \( \check{C}^{\vartheta \nu} \) are conveniently summarized in [Bou02, Plates I–IX, entries (VI)].

Figure 1 displays the values that will be relevant for us. In general, the Cartan matrix and its inverse are block matrices with the Cartan matrices of each irreducible component on the diagonal and all off-diagonal blocks zero, so the coefficients can be computed one component at a time.

The Cartan matrices are the transposes of the transformation matrices describing the change of bases from the simple roots to the respective fundamental weights:

\[
\sigma = \sum_\nu C_{\sigma \nu} \omega_\nu \quad \text{(for } \sigma, \nu \in \Sigma) \\
\vartheta = \sum_\nu \check{C}_{\vartheta \nu} \check{\omega}_\nu \quad \text{(for } \vartheta, \nu \in \Theta) 
\]

We can therefore express the \((\Theta^\vee)^\perp_\mathbb{Q}\)-component of a fundamental weight \( \omega_\vartheta \) with \( \vartheta \in \Theta \) in terms of these matrices.

5.4 Lemma. Let \( \omega_\vartheta \) with \( \vartheta \in \Theta \) be a fundamental weight of \( G \), and let \( \Theta_\vartheta \) denote the connected component of \( \Theta \) containing \( \vartheta \).\(^7\) Write the projection of \( \omega_\vartheta \) onto \((\Theta^\vee)^\perp \) in the basis \( \{ \omega_\beta \mid \beta \in \Sigma-\Theta \} \):

\[
\pi^\perp(\omega_\vartheta) = \sum_{\beta \in \Sigma-\Theta} c_{\vartheta \beta} \omega_\beta 
\]

Then the coefficients \( c_{\vartheta \beta} \) are given by

\[
c_{\vartheta \beta} = \begin{cases} 
-C_{\vartheta \beta} & \text{if } \beta \text{ has a neighbour } \vartheta_\beta \text{ in } \Theta_\vartheta \\
0 & \text{otherwise}
\end{cases}
\]

\(^6\)For \( \vartheta, \nu \in \Theta \), we have of course \( \check{C}_{\vartheta \nu} = C_{\vartheta \nu} \), but \( \check{C}^{\vartheta \nu} \) may be different from \( C^{\vartheta \nu} \).

\(^7\)This is intentional abuse of language. To be more precise, we would have to write: “Let \( \Theta_\vartheta \) denote the subset of \( \Theta \) that corresponds to the connected component of the Dynkin diagram of \( \mathcal{R}_\Theta \) that contains the node corresponding to \( \vartheta \).”
then the coefficients $m^\vartheta$ are given by

$$m^\vartheta_\beta = \begin{cases} (C^{\vartheta\vartheta}_\beta + C^{\vartheta_1\vartheta_0}_\beta) & \text{if } \beta \text{ has a neighbour } \vartheta_\beta \text{ in } \Theta_\vartheta \\ 0 & \text{otherwise} \end{cases}$$

The values of $C^{\vartheta\vartheta}_\beta + C^{\vartheta_1\vartheta_0}_\beta$ are displayed in Figure 2. The values $C_{\vartheta\vartheta_\beta}$ may be determined using Figure 4. (Of course, only the first five cases are relevant.)

5.3 The marking scheme

Corollary 5.5 gives an explicit description of the twist vectors $m^\vartheta = (m^\vartheta_\beta)_{\beta \in \Sigma - \Theta}$ for each root $\vartheta \in \Theta$. However, we see from Theorem 5.3 that only a small part of this information is relevant for determining whether the twisted Witt groups/Tate cohomology groups of $G/P$ vanish. In particular:
The number underneath a root \( \vartheta \) indicates the value \( \bar{C}^{\vartheta \vartheta} + \bar{C}^{\vartheta \circ \vartheta} \), where \( \vartheta_\beta \) is the circled root in each diagram. These values are easily computed from Figure 1. The arrows indicate the involution \( \vartheta \mapsto \vartheta^\circ \) on \( \Theta \). (Diagrams of types \( E_8, F_4 \) and \( G_2 \) are not displayed as they cannot occur as proper subdiagrams.)

A simplified version of Figure 2, indicating only for which self-dual roots \( \vartheta \) the value \( 2\bar{C}^{\vartheta \vartheta} = \bar{C}^{\vartheta \vartheta} + \bar{C}^{\vartheta \circ \vartheta} \) is odd.
(i) We only need to know those $\mathbf{m}^\vartheta$ for which $\vartheta$ is self-dual ($\vartheta^\vartheta = \vartheta$).

(ii) We only need their reductions $\overline{\mathbf{m}}^\vartheta$ modulo two.

(iii) We do not need to keep track which twist vector belongs to which root $\vartheta$: we only need to know which twist vectors $\overline{\mathbf{m}}^\vartheta$ occur for the collection of all self-dual roots of $\Theta$.

Given (i) and (ii), we may simplify Figure 2 to Figure 3. By (iii), we can summarize the relevant information by decorating the Dynkin diagram of $G/P$: for each self-dual root $\vartheta$ of $\Theta$, we add a mark connecting all those neighbours of $\Theta_\vartheta$ for which $\overline{\mathbf{m}}_\vartheta^\beta$ is non-zero. That is, if $\overline{\mathbf{m}}^\vartheta$ has exactly one non-zero entry, we simply mark the corresponding neighbour in $\Sigma$; if $\overline{\mathbf{m}}^\vartheta$ has several non-zero entries, we add a mark that connects all the corresponding neighbours.

Corollary 5.5 implies that the marks of our Dynkin diagrams only depend on the types of the connected components of $\Theta$ and on the edges by which these components are connected to their neighbours in $\Sigma$. Thus, as claimed in Section 1.3, it suffices to consider connected components of $\Theta$ in our marking scheme. The precise rules are now easily derived, as we illustrate with a few examples.

First, consider the case when $\Theta \subset \Sigma$ is of the form $A_l \subset A_n$, and suppose $A_l$ has neighbours $\beta_1$ and $\beta_2$ on either side:

The same reasoning works for $A_l \subset B_n$, except that in this case it can happen that the neighbour $\beta_2$ is connected to $A_l$ via a double line with an arrow pointing away from $A_l$. In that case, we find that $C_\vartheta^{\beta_2} = -2$, so $m^\vartheta_{\beta_2}$ is even and only $\beta_1$ gets marked. Thus, the example from further above should be decorated with the following marks:

As another example, consider the case of $B_l \subset B_n$. Let $\beta$ be the unique neighbour of $B_l$:

All roots of $B_l$ are self-dual. However, we see from Figure 3 that $2C^{\vartheta_1\beta_1}$ is odd only for the shortest root $\vartheta_1$ of $B_l$. The value of $C_\vartheta^{\beta_1\beta}$ is once again $-1$, so we find that $m^\vartheta_{\beta_1} = 2C^{\vartheta_1\beta_1}C_{\beta_1\beta}$ is odd and $\beta$ gets marked:
