Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Background: The COVID-19 pandemic required a rapid response and need for real-world data in cancer patient care. The nationwide, real-time coordinated UKCOMP reporting network provided an immediate solution.

Methods: The ability to set up an interdisciplinary multi-organisational team quickly, covering expert knowledge from clinical, legal, statistical, and computer science was essential. The technical infra-structure allows clinician-led anonymised data entry and rapid dissemination of results with a clinical (RedCap) database as core. However, the development of a national cancer reporting network was crucial for the viability of the project. From its inception in March 2020 the reporting network was established via 4 iterative phases.

Results: Within the first 4 weeks, >50 centres were involved with coverage throughout the UK: Expansion has continued with >70 centres within 6 weeks reporting over 1200 COVID positive cancer patients. This was achieved through a 4-phase approach: phase 1 - Outline: This involved project protocol development where key data and timelines were confirmed by a small project team followed by whole-team sign-off. phase 2 - Engagement: This involved identification and engagement of existing groups to establish an initial network. Professional body endorsement led to increased recognition and utilisation of their membership networks. Finally regional leads were identified, phase 3 - Invitation: The third phase involved the distribution of a formal invite letter via identified networks. Project specific email and standard mailing lists were created to enhance network identity and communication. phase 4 - Consolidation: Early development of an interactive project website and focus on communication via social media with varied content consolidated interest and led to further extension.

Conclusions: Real-time reporting of real world data can be achieved with clearly defined project phases, standardised documentation and an iterative recruitment process. The COVID-19 pandemic necessitated a rapid response, proving that similar development of a national cancer reporting network was crucial for the viability of the project. From its inception in March 2020 the reporting network was established via 4 iterative phases. Legal entity responsible for the study: The authors.

1704P COVID-19 mortality in patients receiving anti-cancer therapy in a UK national cancer centre

A. Wu, C.C.T. Sng, S. Benaffi, N. Chopra, M. Galazi, A.J.X. Lee, D. Ottaviani, G.B. Soosaipillai, Y.N.S. Wong, H.M. Shaw

Cancer Division, University College London Hospitals NHS Foundation Trust, London, UK

Background: The COVID-19 (C19) pandemic has prompted alterations to systemic anti-cancer therapy (SACT) due to concerns of immunosuppression and healthcare exposure. However, the effects of SACT on mortality in patients who acquire C19 are not well understood. As a national cancer centre within a major C19 hotspot, we seek to address these risks at scale.

Methods: Patients with a history of solid cancers and laboratory confirmed C19 (1 Mar to 31 May 2020) were included. Haematological malignancies were excluded. The primary outcome was time from C19 diagnosis to death. The last follow-up date was 22 Jun 2020.

Results: We identified 94 cancer patients; 62 males (median age 73, BMI 24.9), and 32 females (median age 65.8, BMI 25.7). 24 (26%) cancers were the most common, followed by gastrointestinal (n = 23), thoracic (n = 15), and gynaecological (n = 9) cancers. 25 patients received SACT: chemotherapy (n = 15), endocrine therapy (n = 8), immunotherapy (n = 4), and targeted anti-cancer therapy (n = 2). 16 patients received SACT with palliative intent. Patients on SACT had a greater incidence of metastatic disease (48% vs 10.6%, p < 0.001) and were younger (median age 62.5 vs 73.0, p < 0.001). They were also more likely to have renal impairment (p = 0.02), lymphopaenia (p = 0.01) and anaemia (p = 0.04) compared to those not on SACT. The univariate analysis showed age and co-morbidities were associated with mortality (Table). Adjusting for age, ethnicity, co-morbidities and the presence of metastatic cancer, SACT was an independent risk factor for C19 mortality (HR 2.46, 1.09 – 5.5, p = 0.03). Age, South Asian ethnicity, hypertension and cerebrovascular disease were also independent risk factors for C19 mortality.

Table: 1704P Univariate analysis of key variables associated with COVID-19 mortality

| Variable                  | Alive (S) | Dead (D) | p-value |
|---------------------------|-----------|----------|---------|
| Systemic anti-cancer therapy | 13 / 24.5% | 12 / 28.3% | 0.81    |
| Age (years)               | 66 (17)   | 78 (11)  | <0.01   |
| C-reactive protein (mg/L) | 60.4 (87) | 183.7 (215.3) | <0.01   |
| Hypertension*             | 16 / 30%  | 21 / 51%  | 0.04    |
| Cardiovascular disease*   | 8 / 15%   | 10 / 24%  | 0.25    |
| Lymphocytes (10^9/L)      | 0.85 (0.68) | 0.66 (0.57) | 0.07    |
| Creatinine (µmol/L)       | 79 (30)   | 83.5 (64.7) | 0.44    |
| Haemoglobin (g/L)         | 121 (18)  | 116 (29)  | 0.20    |
| Leucocytes (10^9/L)       | 7.15 (4.03) | 9.35 (7.46) | 0.23    |
| Neutrophils (10^9/L)      | 5.53 (3.88) | 7.52 (5.91) | 0.14    |

* shown as n / %, † shown as median (IQR)

Conclusions: C19 infection poses a substantial risk to cancer patients and our data suggests that SACT is an independent risk factor for mortality in C19 infection. These findings call for a nuanced approach to C19 risk, focusing on established risk factors such as age and co-morbidities to guide treatment decisions. Background: Cancer patients are more susceptible to infections and potentially at higher risk to develop COVID-19. Tumor type and antitumor treatment may also affect both the susceptibility to and the severity of SARS-CoV-2.

Methods: To analyze the distribution of patients who developed COVID-19 during active antineoplastic therapy and the related clinical course by tumor type, stage and class of antileukemic biology (chemo, immunology, biological, others) in a multicenter, retro-prospective, observational study was proposed to the Hospital Medical Oncologic Units of the National Health Service in Italy (168 centers of the Collegio Italiano dei Primari Oncologi Medici Ospedalieri –CIPOMO). Data were collected on de-mographics, tumor characteristics, treatment setting, type of ongoing antitumor therapy and COVID-19 clinical course (phenotype, hospitalization, therapy, duration and outcome). Eligibility required a positive COVID-19 molecular test before May 4th, 2020 and at least 1 course of antitumor therapy delivered after January 15th.

Results: At the present analysis data are available for 116 of 168 centers (7 declined, 28 pending, 17 data awaited). 64 of 116 centers (55%) had COVID-19 positive cases (cases /center: median 3, range 1-40). At these 64 centers, 283 positive cases (males (n = 2).
