KEYWORDS
Alzheimer’s disease; Cognitive impairment; Periodontitis; Oral microbiome

Background/purpose: Alzheimer’s disease (AD) is a neurodegenerative disorder and the most common form of dementia. The etiology for AD includes age, genetic susceptibility, neuropathology, and infection. Periodontitis is an infectious and inflammatory disease which mainly causes alveolar bone destruction and tooth loss. The evidence of a link between AD and periodontitis remains controversial. Thus far, studies reviewing the association between AD and periodontal disease have been insufficient from the viewpoint of the oral microbiome. The aim of this review was to focus on studies that have explored the relationship between the oral microbiome and AD development by using the next-generation sequencing technique.

Materials and methods: A comprehensive electronic search of MEDLINE via PubMed, EMBASE, Scopus, and Google Scholar was conducted. The keywords included dementia, Alzheimer’s disease, cognitive impairment, periodontitis, and oral microbiome.

Results: This review included 26 articles based on eligibility criteria. Epidemiologic researches and post-mortem studies showed that the presence of periodontitis is associated with cognitive decline, suggesting a possible role of periodontal pathogens in the pathogenesis of Alzheimer’s disease.
Introduction

Over 55 million people live with dementia globally, with Alzheimer’s disease (AD) being the most common cause of dementia, contributing to 50%–60% of cases. AD is clinically diagnosed based on memory loss, impaired language functions, impaired visuospatial abilities, impaired judgment, and changes in personality. Aging is the most obvious risk for the disease, but genetic and acquired factors also play a major role in AD. The histological characteristics of AD include neuron destruction and abnormal deposition of intraneuronal tau neurofibrillary tangles and extracellular amyloid beta (Aβ) protein plaques in the cerebral neocortex. The abnormally hyperphosphorylated tau protein inhibits assembly and disrupts microtubule network in brain cells, causing synaptic loss and neuron death. Aβ is generated by the improper cleavage of the amyloid precursor protein. Aβ42 is the dominant variant of senile plaques in brains affected by AD. Aβ induces hyperphosphorylation of tau in neurons and causes neuritic degeneration. Systemic inflammation may also cause neuroinflammation and contribute to AD pathology. Studies have shown that individuals with higher inflammatory state are more likely to develop cognitive decline. Inflammatory cytokines such as tumor necrosis factor alpha and interferon gamma increase Aβ production, which suggests a possible pathway by which systemic inflammation accelerates AD development. Animal studies have revealed that neuronal inflammation induced by intrainteritoneal lipopolysaccharide (LPS) injection increases Aβ42 production, astrocyte activation, and neuronal death, along with memory impairment.

The establishment of the gut–brain axis connected gastrointestinal microbiota with cognition decline, suggesting a possible association between bacteria and AD development. Bacterial products such as LPS and short chain fatty acids (SCFA) can modulate the peripheral and central nervous system and act as a potential pathogenic link between the gut microbiota and amyloid pathology in AD. SCFA have also been demonstrated to regulate microglia maturation and function in animal studies, which may alter the host’s immune response. Post-mortem studies have reported greater levels of LPS and Escherichia coli DNA in AD human brains compared to control groups, with LPS colocalized with Aβ amyloid plaque, suggesting that Gram-negative bacteria are associated with AD pathogenesis.

The oral cavity has the second largest distribution of microorganisms after the gut, harboring over 700 microbiome species. The Human Oral Microbiome Database includes 619 oral taxa that belong to 13 phyla, as follows: Actinobacteria, Bacteroidetes, Chlamydiae, Chloroflexi, Euryarchaeota, Firmicutes, Fusobacteria, Proteobacteria, Spirochaetes, Saccharibacteria, Synergistetes, Tenericutes, and Acanthobacteria. The oral—gut—brain axis is considered direct and indirect evidence that oral microorganisms are associated with immunological mechanisms in the brain, particularly periodontal pathogens. Periodontitis is an inflammatory disease of infectious origin, which may progress to a systemic condition and disrupt the immune system and cause dysbiosis of the oral cavity, gut, and other locations. Past epidemiological studies have revealed a correlation between AD and periodontitis occurrence. A study on dementia in monozygotic twin pairs also revealed that tooth loss before the age of 35 is a significant risk factor for AD. Because the genetic influence has been isolated from environmental factors, the inflammatory state caused by periodontitis may contribute to the development of AD. Although the mechanism remains to be determined, studies exploring post-mortem brain tissues have shown the presence of various bacteria, including Porphyromonas gingivalis and Treponema denticola, which are part of the oral microbiome, in AD patients. Animal studies have revealed that periodontal pathogens can access the brains of mice and may contribute to the development of AD. Iida et al. presented an animal model that showed how P. gingivalis exacerbates the pathological features of AD. Possible pathways that allow P. gingivalis and other microorganisms to influence the brain include (1) the bloodstream and a weakened blood–brain barrier affected by age and ongoing infections or inflammation, (2) the olfactory and trigeminal nerves, and (3) direct access through perivascular spaces. The definitive pathway should be explored for a better understanding of the 2 diseases.

Microbiomes that are difficult to detect using traditional cultivation methods can be identified using 16S rRNA gene clonal analysis. An analysis of 16S rRNA gene sequences identified 1179 taxa, of which only 24% were named, 8% were cultivated but unnamed, and 68% were uncultivated phylotypes, which demonstrated how culture-independent molecular biology methods broaden our understanding of the oral microbiome. New
candidate pathogens for caries, periodontal diseases, and endodontic infection have also been identified using 16S rRNA gene amplification. However, the high cost and technical sensitivity of 16S rRNA gene amplification, followed by cloning and Sanger sequencing, make analyzing large numbers of samples difficult. Next-generation sequencing (NGS) provides greater sampling depth and detection for low-abundance taxa with a higher throughput compared to the classic Sanger technique. The limitation of NGS is that the short length of reads may be insufficient for bacterial identification, thus most studies using NGS have focused on hypervariable regions of the 16S rRNA gene, which can still be informative despite short length reads.

NGS is more sensitive than traditional methods and may provide insight into the oral microbiome. Thus far, the use of the NGS technique has been lacking in studies reviewing the connection between AD and periodontal disease. Hence, this review focused on studies that explored the relationship between the oral microbiome and AD development using the NGS technique.

Materials and methods

Search strategy

A comprehensive electronic search of MEDLINE via PubMed, EMBASE, Scopus, and Google Scholar was conducted for human studies published in English up to November, 2021 by using of keywords such as dementia, Alzheimer’s disease, cognitive impairment, periodontitis, periodontal disease, and oral microbiome. The inclusion criteria were as follows: (1) Investigating the prevalence of periodontitis in AD and cognitively normal patients; (2) Investigating the clinical parameters of periodontitis in AD patients and healthy controls; (3) Investigating the composition of the oral microbiome in patients with AD and healthy controls. The exclusion criteria were as follows: (1) Studies that did not specify AD or recognition impairment caused by dementia; (2) Narrative reviews; (3) Articles that were not written in English.

Outcome measures

AD and periodontal measures were included in the review. The AD measures were as follows: (1) Mini-Mental State Examination (MMSE) (2) Hasegawa Dementia Scale-Revised scores, (3) Raven’s Coloured Progressive Matrices (RCPM) test, (4) Visual-Paired Associate (VisPA) task, (5) Verbal-Paired Associate (VerPA) task, (6) 2-min Digit Symbol Substitution Test (DSST), (7) Spatial Copying Task, (8) Block Design Test (BDT), (9) Alzheimer’s Disease Assessment Scale, (10) East Boston Memory Test, (11) Clock-Drawing Test, (12) Clinical Dementia Rating scale, (13) Sum of Boxes, (14) Aβ deposition. The periodontal measures were as follows: (1) Inflammatory markers, (2) clinical attachment level (CAL), (3) probing depth (PD), (4) teeth number.

Results

Results of the search

A total of 311 potential articles were identified through the electronic search. After screening, 264 articles were excluded based on their title or abstract. The remaining 47 articles were evaluated through full-text evaluation, and 21 were excluded for failing to meet the inclusion criteria. Finally, 26 articles were included in this review. Among the 26 included studies, 21 were human studies and 5 were post-mortem studies. The 21 human studies consisted of 7 cross sectional studies, 7 cohort studies, and 7 case-control studies.

Study outcomes

All included studies were divided into 5 groups for further assessment in Table 1.

1. Database- and survey-based studies

Six studies assessed the association between AD and periodontitis via database analysis. Four of the studies used the National Health and Nutrition Examination Survey as their data source, and the remaining 2 examined data from the Washington Heights-Inwood Columbia Aging Project and National Health Insurance Research Database of Taiwan. The numbers of included patients ranged from 219 to 27,963, and the inclusion criteria ranged from age over 45 years to age over 65 years. Because of the nature of these studies, most of them either diagnosed AD based on ICD code 331.0 or did not mention how they diagnosed AD. Beydoun et al. reported that clinical periodontal parameters, namely PD and CAL, had a marginal association with incident AD risk. Four studies investigated the effect of microorganisms using serum immunoglobulin G (IgG) titers. Campylobacter rectus, P. gingivalis, and the Red-Green cluster were associated with higher AD risk, whereas the Orange-Red cluster, P. gingivalis, Prevotella melaninogenica, Streptococcus oralis, and Staphylococcus intermedius were associated with higher AD mortality risk in one study. The same authors also investigated the relationship between periodontal pathogens and Helicobacter pylori and discovered that P. intermedia, C. Rectus, P. nigrescens, P. melaninogenica, and P. gingivalis interacted synergistically with H. pylori with respect to AD incidence. IgG titers to P. gingivalis were associated with cognitive test results such as poor delayed verbal recall and impaired subtraction in a dose-dependent manner. Patients with higher Actinomyces naelundii antibody levels had higher risk of developing AD, whereas those with higher Eubacterium nodatum antibody levels had a lower risk of developing AD.

2. Clinical periodontal parameters

Five studies focused on the relationship between AD and clinical periodontal parameters. The number of participants
### Table 1: Clinical studies investigating the associations between Alzheimer’s disease and periodontitis

| Authors            | Database and sample size | Alzheimer’s disease diagnosis or parameters | Periodontal disease diagnosis or parameters | Outcomes                                                                 |

Noble et al. (2014) 47 Washington Heights-Inwood Columbia Aging Project
219 American patients
- Incident AD: 110
- Control: 109
- Mean follow-up: 5 years
- Age: > 65 years
- No AD at baseline
- High anti-A. naeslundii titer was associated with increased risk of AD.
- High anti-E. nodatum IgG was associated with a lower risk of AD.

### Serum IgG antibody against:
- P. gingivalis
- T. forsythia
- A. actinomyctemcomitans Y4
- T. denticola
- C. rectus
- E. nodatum
- A. naeslundii genospecies-2

Table 1 (continued)

| Authors               | Sample size | AD diagnosis or parameters | Periodontal disease diagnosis or parameters | Outcomes                                                                 |
|-----------------------|-------------|----------------------------|--------------------------------------------|---------------------------------------------------------------------------|
| Iwasaki et al. (2016) | 85 Japanese patients | Parameters: - MMSE > 24 at baseline - Age: > 75 years at baseline | Diagnosis: Severe periodontitis: - AL: ≥ 6 mm at ≥ 2 interproximal sites - PD: ≥ 5 mm at ≥ 1 interproximal sites | - Each tooth that had progression of alveolar bone loss or probing pocket depth increased the overall risk of low scores by 2% to 5%. - Development of new caries or restorations was associated with an increased risk of a low Spatial Copying Task score. - Severe periodontitis was significantly associated with an increased risk of cognitive decline. - Participants with severe periodontitis had a 1.8-point greater decrease in MMSE score than those without severe periodontitis. |
| Kamer et al. (2012)   | 152 Danish patients | Parameters: - People born in 1914 | Diagnosis: Modified Community Periodontal Index score: ≥ 3 for at least 10% of the remaining teeth | - Patients with periodontal inflammation obtained lower mean DSST and BDT scores. - Patients with many missing teeth had lower mean DSST and BDT scores. - Patients with periodontal inflammation had significantly lower adjusted mean DSST scores compared to patients without periodontal inflammation. However, for adjusted BDT, the significance held only for patients with few missing teeth. |
### Clinical studies on AD and inflammatory markers or IgG

| Authors                        | Sample size                                                                 | Alzheimer’s disease diagnosis or parameters                                      | Periodontal disease diagnosis or parameters | Serology sampling site | Inflammatory markers | IgG                  | Outcomes                                                                 |
|-------------------------------|----------------------------------------------------------------------------|----------------------------------------------------------------------------------|--------------------------------------------|-----------------------|----------------------|----------------------|--------------------------------------------------------------------------|
| Sochocka et al. (2017)        | 128 Polish patients (45 males/83 females)                                  | Diagnosis: - DSM-V and NINCDA-ADRDA criteria                                    | Parameters:                              | Sampling:             | Inflammatory markers: | Not mentioned         | - Worse periodontal health status as well as cognitive decline were associated with higher inflammatory state. |
|                               |                                                                            | Parameters: - Teeth number - PD - CAL - BoP - Plaque index                      | Record site:                              |                       |                      |                      |                                                                          |

| Ide et al. (2016)             | 59 English patients (30 males/29 females)                                  | Parameters: - Diagnosis: - CDC/AAP criteria - MMSE                             | Parameters:                              | Sampling:             | Inflammatory markers: | IgG against P. gingivalis | - Periodontitis was associated with an increase in cognitive decline in patients with Alzheimer’s disease, independent of baseline cognitive state. |
|                               |                                                                            | Parameters: - Venous blood                                                      | Parameters:                              |                       |                      |                      |                                                                          |
### Table 1 (continued)

| Authors                | Sample size | Alzheimer’s disease diagnosis or parameters | Periodontal disease diagnosis or parameters | Serology sampling site | Inflammatory markers | IgG                      | Outcomes                                                                 |
|------------------------|-------------|--------------------------------------------|--------------------------------------------|------------------------|----------------------|-------------------------|--------------------------------------------------------------------------|
| Stein et al. (2012)    | 158 American patients | Diagnosis: | Not mentioned | Sampling: | Not mentioned | IgG against - *A. actinomycetemcomitans* - *P. gingivalis* - *C. rectus* - *T. denticola* - *F. nucleatum* - *T. forsythia* - *P. intermedia* | - Antibody levels of *F. nucleatum* and *P. intermedia* were significantly increased at baseline serum drawing in the AD patients compared to the controls. |

#### Studies on AD and the oral microbiome using PCR

| Authors                  | Sample size | Alzheimer’s disease diagnosis or parameters | Periodontal disease diagnosis or parameters | AD markers | Microbiology | Outcomes                                                                 |
|--------------------------|-------------|--------------------------------------------|--------------------------------------------|-------------|--------------|--------------------------------------------------------------------------|
| Leblhuber et al. (2020)  | 20 Austrian patients (11 males/9 females) | Parameters: | Not mentioned | - Neopterin - Tryptophan - Kynurenine | Sampling site: | - P. gingivalis was associated with lower MMSE and Clock-Drawing Test scores. |
|                          |             | - MMSE - Clock-Drawing Test - Magnetic resonance imaging | | | Method | - RNA-based analysis (PerioPOC) |
|                          |             | | | | | Bacteria: |
|                          |             | | | | | - T. denticola/ T. forsythia/ *P. gingivalis*/ *P. intermedia* / *A. actinomycetemcomitans* |
| Laugisch et al. (2018)   | 40 German patients | Diagnosis: | Diagnosis: | - Aβ1-42 - Total tau | Sampling site: | - None of the investigated bacteria were |
|                          |             | - MMSE ≥ 19 | - PD of ≥ 4 mm | | | - Subgingival dental biofilm and GCF |
Studies on AD and the oral microbiome using NGS or the third-generation technique

| Authors            | Sample size | Alzheimer's disease diagnosis or parameters | Periodontal disease diagnosis or parameters | AD markers | Microbiology sampling site and method | Outcomes |
|--------------------|-------------|---------------------------------------------|---------------------------------------------|------------|--------------------------------------|----------|
| Holmer et al. (2021) | 195 Swedish patients | AD: 46, MCI: 40, Subjective cognitive decline: 46, Control: 63, Age: 50-80 years | Diagnosis: NIA-AA diagnostic guidelines | AD: 20, Other forms of dementia: 20, Age: 30–70 years, Caucasian origin, Recently diagnosed with dementia | - AL ≥ 3 mm Parameter: - PI PD - AL - BOP Site: - Six sites of each tooth | Sampling site: - CSF | - Cognitive dysfunction was a significant determinant of subgingival microbial composition and was associated with higher microbial richness and evenness using either alpha or beta diversity measures. More abundant in AD group Overall oral microbial diversity in the AD group tended to be lower than that in the control group. More abundant in AD group |
| Wu et al. (2021)    | 35 Taiwanese patients | Parameters: | Not mentioned | Not mentioned | | Sampling site: - Subgingival dental biofilm Site: - Six sites of each tooth | Method: | |
|                     |             | - Clinical Dementia Rating Scale | - PD ≥ 6 mm Parameters: - PD - BOP - Radiograph | | Method: | - V3-V4 regions of the 16S rRNA gene - Illumina MiSeq | |

Detected in the CSF or serum samples.

- No significant difference was observed in antibody levels against specific bacteria in the CSF or serum between groups.
- In patients with dementia aged up to 70 years, periodontal pathogens did not act as a trigger for developing AD.
| Authors                  | Sample size | Alzheimer’s disease diagnosis or parameters | Periodontal disease diagnosis or parameters | AD markers | Microbiology sampling site and method | Outcomes |
|-------------------------|-------------|--------------------------------------------|-------------------------------------------|------------|--------------------------------------|----------|
| Yang et al. (2021)      | 58          | - Control: 18                              | - SOB                                      |            | Method: Full-length 16S rDNA sequencing | Order:   |
|                         |             |                                            | - MMSE                                     |            | - Lactobacillales (aerotolerant anaerobes) | Order:   |
|                         |             |                                            |                                          |            | - Actinomycetales (anaerobic)             | Order:   |
|                         |             |                                            |                                          |            | - Veillonellales (anaerobic)              | Order:   |
|                         |             |                                            |                                          |            | Method: PacBio single-molecule real-time sequencing | Order:   |
|                         |             |                                            |                                          |            | - Fusobacteria                          | Order:   |

- CRP: C-reactive protein, LPS: Lipopolysaccharide, ADRC: Alzheimer’s Disease Research Center, MCI: Mild Cognitive Impairment
### Liu et al. (2019)

- **Patients**: 78 Chinese patients (39 males/39 females)
- **Diagnosis**:
  - Mild: MMSE ≥ 20
  - Moderate: 10 ≤ MMSE < 20
  - Severe: MMSE < 10
- **Sample size**:
  - AD: 39
  - Control: 39
- **Sampling site**:
  - Saliva
  - QIAamp DNA Investigator Kit
- **Method**:
  - V3-V4 regions of the 16S rRNA gene
  - Illumina Hiseq2500
- **Outcomes**:
  - Alpha diversity analysis showed that there was lower richness and diversity in AD patients.
  - No bacteria were found to be associated with the severity of AD.
  - More abundant in AD group
  - More abundant in controls

### Emery et al. (2017)

- **Sample size**: 26 patients
  - AD: 14
  - Control: 12
- **Inclusion criteria**:
  - Age: 62–98 years
- **Sampling site and method**:
  - Temporal cortex
  - Right hemispheres:
    - Formalin fixed for neuropathological assessment and for immunohistochemical analysis
  - Left hemispheres:
    - Sliced and frozen at −80°C
- **Outcomes**:
  - Many more bacterial 16S reads were yielded from AD samples, strongly suggesting that contamination was not a major issue for these data.
  - Contamination: *Rhizobiales; Methylobacteriaceae*
  - More abundant in AD group
  - More abundant in controls
  - Largest component: *Actinobacteria* Family:
    - *Actinobacteria; Propionibacteriaceae (P. acnes)*
    - *Actinobacteria; Corynebacteriaceae*
| Authors | Sample size | Microbiology sampling site and method | Outcomes |
|---------|-------------|--------------------------------------|----------|
| Siddiqui et al. (2019) | 20 patients (5 males/15 females) | Sampling site:  
- Brain tissue adjacent to the lateral ventricle of the parietal lobe  
- Average storing interval: 16 years  
Method:  
- V3-V4 regions of the 16S rRNA gene  
- Illumina MiSeq | - A wide spectrum of bacteria was detected in samples from both groups, containing both oral and gastrointestinal tract microbiome species.  
More abundant in AD group  
Phylum:  
- Firmicutes  
Family:  
- Pseudomonadaceae: dominating family  
Order:  
- Actinomycetales  
Species:  
- Prevotella  
- Treponema  
- Veillonella  
More abundant in controls  
Phylum:  
- Proteobacteria  
Genus:  
- Fusobacterium |
| Dominy et al. (2019) | 58 patients | Sampling site:  
- Middle temporal gyrus | - Both RgpB and Kgp antigens in brain tissue independently demonstrated a significant correlation with AD diagnosis, tau load, and ubiquitin load.  
More abundant in AD group  
More abundant in controls  
AD markers:  
- Tau (non-phosphorylated/phosphorylated)  
- Ubiquitin  
Methods:  
- Real-time PCR analysis of P. gingivalis  
Antibodies to gingipain: | - P. gingivalis strains W83, ATCC33277, and FDC381 |
Poole et al. (2013) 31

20 patients
- AD: 10
- Control: 10

Sampling site:
- Brain tissue adjacent to the lateral ventricle of the parietal lobe

Method:
Antibodies against - P. gingivalis (LPS and gingipains)
- T. forsythia
- T. denticola

Human brain tissue sections with mouse anti-P. gingivalis revealed strong cellular surface membrane labeling in 4 out of 10 AD cases but not in the non-AD age-matched controls.
- No immunolabeling was observed with anti-T. forsythia antibodies nor with anti-T. forsythia.
- Four out of 10 AD brains exhibited bands characteristic of LPS.

Riviere et al. (2002) 32

Group 1
34 patients (18 males/16 females)
- AD: 16
- Control: 18

Group 2
5 patients (2 males/3 females)
- AD: 3
- Control: 2

Group 3
4 patients (2 males/2 females)

Group 4
33 living patients

Sampling site:
- Frontal lobe cortexes (Group 1)
- Frozen trigeminal ganglia (Group 2)
- TG, pons, and hippocampus (Group 3)
- Saliva (Group 4)

Method:
- Treponema may infect the brain via branches of the trigeminal nerve.

- Lysine-gingipain (Kgp)
- Arginine-gingipain A (RgpA)
ranged from 85 to 591. Four studies included elderly patients only, and one cohort study included patients who were over 28 years old at baseline. The MMSE was used as either the AD diagnosis criterion or cognitive state parameter in 3 studies, and the remaining 2 used the BDT and other exams. The 3 studies that administered the MMSE reported that low cognitive MMSE test scores were associated with tooth loss, probing pocket depth, and alveolar bone loss. Kaye et al. compared patients under 45 years and patients over 45 years and found that the older group has higher alveolar bone loss at baseline and experiences more tooth loss per decade.48 MMSE scores are also consistently lower in older men. Kamer et al. found that patients with periodontal inflammation have lower mean DSST and BDT scores.50 Moriya et al. discovered significant negative correlations between the RCPM test, the VerPA task, or the VisPA task and periodontal status, but no correlation was found between the BDT and periodontal status.50

3. Serology-based studies

Serum inflammatory markers or IgG were investigated in 4 studies to determine the relationship between AD and periodontal disease. The number of participants ranged from 34 to 158. Of the 3 studies that assessed the correlation between inflammatory markers and cognitive states, 2 reported that inflammatory markers are elevated in AD patients compared with cognitively normal patients. Sochocka et al. reported that interleukin-1β (IL-1β), IL-6, IL-10, and tumor necrosis factor-α (TNF-α) are elevated in AD patients. Moreover, Kamer et al. reported that TNF-α is elevated in AD patients but IL-1β and IL-6 are not.51,52 In contrast, Ide et al. did not find any significant relationships between baseline systemic inflammatory markers and cognitive measures.53 Regarding the influence of periodontal pathogens on cognitive impairment, Kamer et al. reported that AD patients are more likely to have positive tests of IgG antibodies against Aggregatibacter actinomycetemcomitans, P. gingivalis, and Tannerella forsythia.52 A retrospective study revealed that AD and mild cognitive impairment (MCI) patients exhibit significantly elevated P. intermedia and Fusobacterium nucleatum antibody levels at baseline, before neurological changes are diagnosed.54 However, conflicting results from a 6-month cohort study showed no significant relationship between the baseline IgG antibody titer to P. gingivalis and the rate of cognitive decline.55

4. Microbiology-based studies

Among 6 studies that focused on the relationship between AD and the oral microbiome, one assessed specific periodontal pathogens via RNA-based analysis, one detected specific microorganisms via DNA real-time polymerase chain reaction, 3 analyzed the V3-V4 or V4 regions of the 16S rRNA gene via NGS, and one investigated the full-length of 16S rDNA using single-molecule real-time sequencing. The number of patients ranged from 20 to 58. One used antibodies against specific pathogens, one used real-time polymerase chain reaction (PCR) against P. gingivalis, one used both Treponema species-specific antibodies and PCR, and 2 analyzed the V3-V4 or V3 regions of the 16S rRNA gene via NGS. Both genetic sequencing studies revealed that Actinobacteria is more abundant in the AD groups, whereas Proteobacteria is more abundant in the control groups.51,62 Dominy et al. focused on P. gingivalis and gingipain in brain tissue, and reported that P. gingivalis DNA is present in brain tissue in AD patients.50 Gingipain was also found to be correlated with AD diagnosis. Poole et al. focused on periodontal pathogens in brain tissue with antibodies against P. gingivalis, T. forsythia, and T. denticola, and reported P. gingivalis antigen expression in AD brain tissue but not in the control group.51 Riviere et al. focused on the detection of Treponema species in brain tissue and reported a higher rate of Treponema species detection in the AD group compared to the control group.52

5. Post-mortem studies

Five post-mortem studies compared the microbiome of the brain tissue of AD patients to that of cognitively normal patients. The number of patients ranged from 20 to 58. One used antibodies against specific pathogens, one used real-time polymerase chain reaction (PCR) against P. gingivalis, one used both Treponema species-specific antibodies and PCR, and 2 analyzed the V3-V4 or V3 regions of the 16S rRNA gene via NGS. Both genetic sequencing studies revealed that Actinobacteria is more abundant in the AD groups, whereas Proteobacteria is more abundant in the control groups.61,62 The 4 gene sequencing studies yielded conflicting results in terms of diversity and abundant species. Holmer et al. reported that the AD group has higher microbiome diversity, Yang et al. did not identify any difference in diversity between MCI and the control group, and Wu et al. and Liu et al. found that the MCI group has lower diversity.57–60 In regards to species abundance, Holmer et al., Yang et al., and Liu et al. all found that the most predominant microbes are similar in the control groups and study groups. Holmer et al. discovered that Actinomyces and Rothia are more common in the control group, whereas Slackia exigua, Lachnospiraceae, and Prevotella oulourum are more common in the AD group.37 Wu et al. found that Firmicutes, Lactobacillales, Actinomycetales, and Veillonellales are more common in the MCI group, whereas Fusobacteria, Bacteroidetes, and Cardiobacteria are more common in the control group.59 Yang et al. found that Pasteurellaceae is more common in the MCI group, whereas Lautropia mirabilis is more common in the control group.58 Liu et al. reported that Moraxella, Leptotrichia, and Sphaerochaeta are more common in the AD group, whereas Rothia is more common in the control group.61,62

Discussion

This systematic review aimed to determine the relationship between periodontitis or periodontal pathogens and AD. Large-scale studies based on databases and surveys agree that the presence of periodontitis is linked to cognitive decline.57,58 This is consistent with the results of clinical studies focusing on the relationship between AD and clinical periodontal parameters.48–50,61,64 However, although an association between periodontitis and cognitive impairment with AD and patients with other forms of dementia (DE- noAD), and the results showed that periodontal pathogens do not act as a trigger for developing AD.56

Leblhuber et al. reported that interleukin-1β (IL-1β) is elevated in AD patients. Moreover, Ide et al. did not find any significant relationships between baseline systemic inflammatory markers and cognitive measures.53 Regarding the influence of periodontal pathogens on cognitive impairment, Kamer et al. reported that AD patients are more likely to have positive tests of IgG antibodies against Aggregatibacter actinomycetemcomitans, P. gingivalis, and Tannerella forsythia.52 A retrospective study revealed that AD and mild cognitive impairment (MCI) patients exhibit significantly elevated P. intermedia and Fusobacterium nucleatum antibody levels at baseline, before neurological changes are diagnosed.54 However, conflicting results from a 6-month cohort study showed no significant relationship between the baseline IgG antibody titer to P. gingivalis and the rate of cognitive decline.55

S. Mao, C.-P. Huang, H. Lan et al.
has been confirmed, whether AD leads to periodontitis or periodontitis is a contributing factor of AD remains controversial. A previous study comparing AD with other forms of dementia showed that dementia affects a patient’s ability to maintain oral hygiene, thus patients with AD are prone to have periodontal disease. Post-mortem studies of AD patients have revealed the presence of *P. gingivalis* LPS in AD patients but not in control patients. Dominy et al. also reported that *P. gingivalis* DNA and gingipain are present in the brain tissue of AD patients. Riviere et al. discovered a higher rate of *Treponema* species detection in the AD group. These findings suggest periodontal pathogens may travel from the mouth to the brain and cause inflammation and eventual destruction of brain tissue. However, brain tissue may be tested for bacteria years after a patient’s death, and this may cause bacterial contamination of brain tissue that was not present during the patient’s lifetime. Therefore, obtaining data from clinical experiments is imperative.

Serology findings suggest that AD is related to higher inflammatory state and elevated periodontal bacteria antibody levels. Ide et al. reported that periodontitis is not related to the baseline cognitive state but is related to cognitive decline over a 6-month follow-up period. However, contrary to other studies, no significant association between baseline serum *P. gingivalis* antibody levels and the rate of cognitive decline was found. This may indicate that *P. gingivalis* is not the sole determining factor of cognitive decline. In addition, tooth loss and a history of periodontitis were not found to be related to cognitive decline, which may indicate that active periodontitis plays a crucial role in cognitive decline. None of the 4 studies have compared serological findings to the severity of AD or the onset timing of AD, which can be discussed in future studies for further understanding of the disease.

Although epidemiology studies have proven that AD is related to periodontitis, the linking mechanism remains uncertain. One study focusing on periodontal pathogens reported that *P. gingivalis* levels are related to lower MMSE scores, and that *T. denticola* and *T. forsythia* levels are related to the concentration of immune biomarkers. These findings hint at the possibility of synergistic effects of different microorganisms, which may alter the host’s immune response. Another study by Laugisch et al., which compared microbiomes in patients with AD and patients with other forms of dementia, did not reveal any significant difference in bacteria antibody levels between groups. However, they discovered elevated levels of anti-pathogen antibodies in the cerebrospinal fluid (CSF) compared to serum in both groups. This highlights the possibility that intrathecal immune response may be triggered by periodontal pathogens. Interestingly, despite the elevated levels of anti-pathogen antibodies in the CSF, none of the investigated bacteria were detected in the CSF or serum samples. Because only specific antibodies were detected, only portions of bacterial components may have entered the brain or these bacteria may reside only in brain tissue. These results differ from those of Dominy et al., who reported that *P. gingivalis* DNA is present in AD brains and CSF. This may be because Laugisch et al. mostly included early-onset AD, which is primarily associated with genetic factors rather than inflammatory factors such as periodontitis. The inclusion of early-onset AD might also influence bacteria antibody levels, which showed no difference between patients with AD and patients with other forms of dementia in the study by Laugisch et al. Future studies may have to differentiate between early-onset and late-onset AD because they may have different immune responses to pathogens, thus leading to different conclusions.

The 4 studies using either NGS or single molecule real-time sequencing had conflicting results in terms of microbial diversity and the relative abundance of bacterial taxa between groups. This difference may be largely caused by the different sampling sites in the 4 studies, rendering the data of these 4 studies incomparable. Holmer et al. sampled the subgingival dental biofilm, and the 3 operational taxonomic units (OTUs) that were more abundant in patients with AD were all anaerobic species, whereas the 3 OTUs that were more abundant in controls were aerobic or facultatively anaerobic species. Lachnospiraceae, which was more common in the AD group, was also found to be more abundant in the gut of the AD group in another study. In addition, Lachnospiraceae is also related to inflammatory diseases, such as metabolic syndrome, obesity, diabetes, inflammatory bowel disease, and liver diseases including chronic liver disease. Wu et al. sampled the supragingival dental biofilm and reported that the cariogenic bacteria *Lactobacillale* and *Streptococcaceae*, along with *Actinomycetaceae* and *Veillonellaceae*, are increased in patients with AD. Interestingly, *Streptococcus mutans* is an amylloid-forming organism and is more abundant in the feces of patients with AD compared with normal individuals, and may therefore be a potential contributor to the development of AD during oral dysbiosis. Yang et al. collected samples from soft tissue surfaces and reported that the opportunistic pathogen *Pasteurellaceae* is abundant in the MCI group. Although this study cannot draw conclusions regarding the relationship between MCI and periodontal condition because of the lack of periodontal records and representative sampling sites of periodontal pathogens, inflammatory markers such as IL-1α, IL10RA, IL13, and TSLP are positively associated with *Pasteurellaceae*, indicating that the oral microbiome may affect inflammatory states. Liu et al. studied the saliva samples of AD patients and found the 3 taxa such as *Moraxella*, *Lep. totchiria*, and *Sphaerochaeta*, which are all Gram-negative bacteria and may induce Aβ plaque formation via LPS, are more abundant in the group of AD patients.

In conclusion, database studies focusing on epidemiologic research and post-mortem studies show that periodontal pathogens may play a role in the pathogenesis of AD. However, the reported microbiomes are inconsistent in the gene sequencing studies, which may be due to different microbiome sampling sites and different cognition standards. To gain a better understanding of the role of the oral microbiome in AD, a standardized sampling site and cognitive test should be implemented. In addition, early-onset AD and late-onset AD should be discussed separately because they have different etiologies. Another limitation of these studies is that the control patients may have already had undiagnosed cognitive impairments, which may require long-term longitudinal studies to test. Future studies that provide periodontal treatment as an intervention are also required to clarify the relationship between periodontal disease and AD.
