Conclusion. Hospital costs and earnings for two common surgical interventions varied substantially under a prospective payment system: SSIs after colon and CABG operations resulted on average in higher costs and lower earnings. A prospective payment system may add a strong financial incentive to reduce SSI rates after colon and CABG operations.

2136. Systematic Review of Surgical Wound Class Reveals Marked Service-Related Disparities and Can Improve Appropriateness of Classification Impacting the Expected Number of Infections and the Standardized Infection Ratio (SIR)
Ayat Abushahmad, MS, CIC; Purisima Linchangco, MD, MPH, CIC; Elizabeth Wise, BSN, RN, CMSRN; Ashley Boldyga, BSHSM; Karen Nachman, MS, PhD; Belkys T. Gomez, RN, MSN; and Jorge P. Parada, MD, MPH; Loyola University Medical Center, Maywood, Illinois

Session: 235. Healthcare Epidemiology: Surgical Site Infections Saturday, October 6, 2018: 12:30 PM

Background. During surgical operations, surgical wounds are classified according to the wound classification system (I—clean; II—clean/contaminated; III—contaminated; and IV—dirty). Accuracy in assessing the degree of wound contamination is crucial since it greatly impacts the risk of a surgical site infection (SSI). Thus, wound classifications (WC) are determinant in calculating the expected number of SSIs. At our institution we suspected that surgical wounds were not always accurately classified, and were skewed toward under-classifying wound class. This contributed to incorrect and reduced expected SSIs and an inflated SSI Standardized Infection Ratio (SIR).

Methods. An independent team reviewed 273 surgical cases from our top priority SSI reduction areas: Prosthetic knees (KPRO), coronary artery bypass grafts (CABG), abdominal hysterectomies (HYST) and colorectal surgery (COLO). Whenever there was discordance in surgeon vs. review team WC, an arbitrator reviewed the case with the surgeon and corrected misclassified cases as appropriate. Reclassifications were documented in the medical record as well as in the National Healthcare Safety Network (NHSN) system.

Results. Figure 1 shows all WC reviews. Overall, 14% of all surgeries were misclassified and 95% of misclassifications were under-classifications. Appropriateness of WC varied widely by surgical service, with 100% concordant WC for KPRO, while 9% of HYST and CABG were misclassified, and fully 38% of COLOs were misclassified (Figure 1). These errors led to under predicting expected SSIs and, if not corrected, would have a measurable impact on our SSI SIR.

Conclusion. The inaccurate classifications vary by service/surgery, but in COLO we found them to be common and overwhelmingly skewed toward under-classification, which had a measurable impact on the expected number of SSIs and on SSI SIR. Focusing efforts on surgeries more prone to misclassification (such as COLO rather than KPRO) may be a worthwhile focused quality improvement effort.

2137. Risk Factors for Surgical Site Infection After Joint Replacement Surgery: Data from the Swiss National Surveillance System
Niccolo Ruetti, MD; Andrew Atkinson, MA; Nicolas Troleset, MD MSc; Marie-Christine Eisenring, RN; Marcel Zerahlen, PhD; Stefan P Kuster, MD MSc; Andreas Widmer, MD MS; and Jonas Marschall, MD; Infectious Diseases and Hospital Epidemiology, University Hospital Bern, Bern, Switzerland; Department of Infectious Diseases, Bern University Hospital, Bern, Switzerland; Valais Hospital, Sion, Switzerland; Institute for Social and Preventive Medicine, Bern, Switzerland; Infectious Diseases and Hospital Epidemiology, University Hospital Zurich, Zurich, Switzerland; University Hospital Basel, Basel, Switzerland

Session: 235. Healthcare Epidemiology: Surgical Site Infections Saturday, October 6, 2018: 12:30 PM

Background. Surgical site infections (SSIs) are infrequently observed after joint replacement surgery but have devastating consequences. Since 2009, a large network of Swiss hospitals prospectively collects data for the national SSI surveillance system. The aim of this observational study was to identify risk factors for SSI among patients undergoing elective hip and knee arthroplasty procedures.

Methods. Risk factors for SSI were identified using both univariate and multivariate logistic regression, appropriately adjusted for hospital level correlation effects among the 173 participating hospitals. We included procedural characteristics and risk categories in our analysis.

Results. We analyzed a total of 113,495 joint replacement procedures that occurred between June 2009 and September 2017. A 12-month follow-up was completed in 92.5% of cases. Overall, the cumulative SSI rate was 1.3% (n=1,458), varying from 1.1% for knee to 1.4% for hip arthroplasty. Repeat surgery (unplanned or planned), higher ASA level, and longer than anticipated procedural time were associated with a significantly increased risk of infection (figure). Ninety-one percent of all SSIs (1,328) were detected in the post-discharge follow-up. Risk factors for pre-discharge SSIs were very similar to those mentioned above. Fifty-six percent of SSIs were observed within 30 days; 27% from 30 to 90 days after incision and 17% were observed >90 days after the procedure.

Conclusion. The SSI incidence after joint replacement surgery was low, with no significant difference between knee and hip surgery. Almost all SSIs occurred post-discharge, with risk factors being broadly the same, independent of when the infection occurred. Limiting the follow-up period to 90 days would have resulted in missing 17% of SSIs, which argues in favor of extended follow-up.

2138. Impact of De-escalation of Antibiotic Surgical Prophylaxis in Lung Transplant Recipients
Sumit Gandhi, PharmD Candidate; Bharath Ravichandran, PharmD; Dawn Keiselle Lockman, PharmD; Kerri A. Thom, MD; Anthony Amoroso, MD; Mehrnaz Pajounian, PharmD; and Emily Heil, PharmD, BCPS-AQID; University of Maryland School of Pharmacy, Baltimore, Maryland; University of Maryland Medical Center, Baltimore, Maryland; University of Iowa College of Pharmacy, Iowa City, Iowa; University of Maryland School of Medicine, Baltimore, Maryland; University of Maryland School of Medicine, Institute of Human Virology, Baltimore, Maryland; Pharmacy Practice and Science, University of Maryland School of Pharmacy, Baltimore, Maryland

Session: 235. Healthcare Epidemiology: Surgical Site Infections Saturday, October 6, 2018: 12:30 PM

Background. Guidelines for perioperative antibiotic prophylaxis in lung transplantation (LT) are limited; since Pseudomonas colonization has been linked to acute graft rejection and development of bronchiolitis obliterans syndrome, some centers utilize an anti-pseudomonal β-lactam as part of the surgical prophylaxis regimen. Internal data from our large academic medical center, a center that does not frequently transplant cystic fibrosis patients, identified low rates of Pseudomonas colonization and infection in LT patients. The surgical prophylaxis regimen was therefore narrowed from vancomycin/piperacillin–tazo-bactam (VPT) in 2013 to vancomycin/ceftixime–one (VCT). The purpose of this study was to examine the protocol change to the incidence of Pseudomonas isolation in the post-operative period for lung transplant recipients.

Methods. This was a single-center, retrospective quasi-experimental before-after study of lung transplant recipients from July 2006 to February 2017 comparing patients

Disclosures. A. Widmer, Swiss national science foundation: Grant Investigator, Grant recipient.
who received VPT to VCT for surgical prophylaxis. Patients receiving other surgical prophylaxis regimens due to allergy or colonization history were excluded. Donor and recipient culture data from bronchoscopy samples were collected to determine the incidence of *Pseudomonas* in the 14-day post-transplant period. The secondary outcome was the incidence of post-transplant CDC-defined pneumonia. Statistical analysis was performed using SAS 9.4 (Cary, NC).

**Results.** One hundred patients were included in the pre-protocol group (VPT), and 65 in the post-protocol group (VCT). *Pseudomonas* was recovered in recipient BALs on post-day 2-14 in 8 (8%) patients in the VPT group compared with 5 (7.7%) patients in the VCT group (P = 1.0). Mean time to peak colony isolation was 5.4 days in the VPT group compared with 5.4 days in the VCT group. Incidence of pneumonia on post-op day 2-14 was 6% in the VPT group vs. 3% in the VCT group (P = 0.48). Surgical site infections were rare in the VPT group with an incidence of 1.5% (1/65). A total of 51 cases were observed. ChloraPrep was used most often, followed by two-step PVP Scrub and Paint, CHG and DuraPrep. ChloraPrep was applied dry time were measured and compliance was calculated as a percentage. Infection Prevention for the University hospitals audited appropriate- ness of skin prep for compliance with manufacturer’s directions and whether sufficient drying time was allowed. Skin prep was done appropriately less than 50% of the time. BD assessed skin prep practices in May 2017 using a standardized observation tool that evaluated methods for skin prep, compliance to pending dry time for ChlorPrep. Duraprep, and other CHG and iodine solutions. Prep time and dry time were measured and compliance was calculated as a percentage. Adequate dry time was ensured for each skin prep procedure.

**Conclusion.** Isolation of *Pseudomonas* was rare in both time periods and an increase was not detected when anti-pseudomonal coverage was removed from the surgical prophylaxis regimen. Safe desescalation of surgical prophylaxis regimens are an important antimicrobial stewardship initiative.

2139. Improving Peri-Operative Skin Prep Technique at a Large Tertiary Medical Center: A Quality Improvement and Educational Initiative

Barbara Hasabn, RN, BSN, CIC®; Suzan New, MS BSN RN CNOR®; Barbara Crim, MBA BSN RN CNOR®; Lena Pearson, RN BSN MS CNOR®; LeAnn Williams, RN BSN®; Boramarine Arocha, PhD, MS, MT(ASCP), SM, CIC, FAPIC® and Julie Trivedi, MD®, 1IPC, William P. Clements Jr University Hospital/UT Southwestern Medical Center, Dallas, Texas, 2William P Clements Jr University Hospital/UT Southwestern Medical Center, Dallas, Texas, 3BD, San Diego, California, 4UT Southwestern University Hospitals and Clinics, Dallas, Texas, 5Department of Medicine, Division of Infectious Diseases, UT Southwestern Medical Center, Dallas, Texas

**Session:** 235. Healthcare Epidemiology: Surgical Site Infections

**Saturday, October 6, 2018: 12:30 PM**

**Background.** Surgical site infections (SSIs) are the most common cause of health-care associated infections. As part of our campaign to reduce SSIs at UT Southwestern Medical Center in Dallas, TX, we sought out to audit skin prep practices with the initial focus on application technique and a secondary focus on choice of product.

**Methods.** Infection Prevention for the University hospitals audited the appropri- ateness of skin prep for compliance with manufacturer’s directions and whether sufficient drying time was allowed. Skin prep was done appropriately less than 50% of the time. BD assessed skin prep practices in May 2017 using a standardized observation tool that evaluated methods for skin prep, compliance to pending dry time for ChlorPrep. Duraprep, and other CHG and iodine solutions. Prep time and dry time were measured and compliance was calculated as a percentage.

**Results.** A total of 51 cases were observed. ChlorPrep was used most often, followed by two-step PVP Scrub and Paint, CHG and DuraPrep. ChlorPrep was applied correctly 44% of the time and DuraPrep 6% of the time. ChlorPrep prep time was compliant only 6% of the time. Dry time compliance was 45% for ChlorPrep and 50% for DuraPrep. Overall method was correct 41% of the time, proper prep time 3% (compared with a national average of 44%), proper dry time of 41%. A skin prep task force worked to simplify the products available and clarified instructions for DuraPrep. Overall application method was correct 41% of the time, proper prep time 3% (compared with a national average of 44%), proper dry time of 41%. A skin prep task force worked to simplify the products available and clarified instructions for use. Inservice training programs were developed. Nursing educators developed an audit and competency tool for monitoring.

**Conclusion.** The correct application technique, prep time and dry time were achieved in <50% of the time. BD observations. Of all the time periods for each of these categories were <50% as well. The results of the assessment at UT Southwestern are not unique and reflect a larger issue in how skin prep is performed across the coun-
ty. It became clear that doing a deeper dive to understand the barriers in implementing an appropriate technique and pending dry time for ChlorPrep was needed. We found the number of people in the OR was potentially associated with SSIs. After following NDHHS rec-
ommendations to limit door openings and OR traffic, there were no additional cases. Additionally, we outlined our methodology in a publically-available response guideline online at the NDHHS web page.

2141. Characteristics and Prognosis of Patients with a Prosthetic Vascular Graft Infection (PVGI): A Prospective Cohort of 200 patients

Armelle Pasquet, MD®, Olivier Robineau, MD®, Michel Valette, MD®, Pier-Vito D’Elia, MD®, Sylvie Vandamme, CST®, Olivier Leroy, MD®, Barthelemy Lafon-Desperts, MD®, and Eric Sennens, MD®, 1Infectious Diseases, DRON Hospital, Clichy, France, 2Vascular Surgery, Dron hospital, Tourcoing, France, 3ICU, Dron Hospital, Tourcoing, France

**Session:** 235. Healthcare Epidemiology: Surgical Site Infections

**Saturday, October 6, 2018: 12:30 PM**

**Background.** The aim of the present study was to describe the characteristics and prognosis of patients admitted for a PVGI and to assess the factors associated with the occurrence of PVGI and the patients’ outcome.

**Methods.** All consecutive patients admitted in our department between January 1, 2000 and January 1, 2018 for a PVGI were enrolled in the present prospective cohort study. PVGIs were divided into extravascular (femoro-femoral, femoro-popliteal and axillo-femoral) and caviary (aorto-iliaic, aorto-femoral, ilio-femoral, aorto), into “early” infection (<4 months) and late. Patients’ baseline characteristics and their follow-up were described, and factors associated with death were assessed by using a logistic multivariate regression model.

**Results.** Overall, 200 patients were included during this period. The median age of patients was 69 years [IQR: 61–78], mainly of men (86%). One hundred and six-
teen patients had an intracavitary PVGI (58%). Enterobacteriaceae and MSSA were the most frequent pathogens (n = 60 and 59), followed by coagulase negative staph-
ylococci (n = 30), Streptococcus (n = 26) and enterococcus (n = 25). Surgery with explantation of the infected graft was performed in 102 patients (53%). Culture of material samples taken during surgery were polymicrobial in 67 patients (34%). After surgery, the median follow-up of patients was 7.5 months [IQR: 2–19] during which 30 presented a failure (15%) and 85 patients died, 41 due to the PVGI (21%). Factors independently associated with mortality and/or PVGI were: to be under 60 years (OR = 8.2; P < 0.01), to stay in ICU for more than 6 days (OR = 5.9; P = 0.01) and to have an intracavitary PVGI (OR = 9.0; P = 0.02). Antibiotic therapy regimen combining rifampicin to another antibiotic was associated with a decreased mortality (OR = 0.13; P = 0.01).

**Conclusion.** Our results suggest that the prognostic of patients admitted for PVGI depends on the site of infection and the occurrence of a shock after the admis-
sion. We found a better prognosis for patients with an extravascular PVGI, without septic shock. Finally, PVGI treated with an antibiotic combination including rifampicin had a better outcome.

2142. Understanding Errors in Sterile Processing of Surgical Instruments That Lead to Need for Immediate Use Sterilization in the Operating Room

John Farrell, MD; Medicine and Microbiology, University of Illinois, Peoria, Illinois

**Session:** 235. Healthcare Epidemiology: Surgical Site Infections

**Saturday, October 6, 2018: 12:30 PM**

**Background.** “Flash sterilization”, an outdated term for immediate-use steriliza-
tion. Immediate use is broadly defined as the shortest possible time between a steri-
lized item’s removal from the sterilizer and its aseptic transfer to the sterile field for use in the procedure for which it was sterilized, but at our institution, immediate-use sterilization of individual unwrapped objects has a very specific definition: this is a process performed by the same surgeon, and during the same period of time but did not develop infections.

**Results.** In 2016, of the 452 procedures at this CAH, 17 developed SSIs (rate = 3.8%). SSIs occurred following the most invasive procedures being performed by the same surgeon and adhered to in 17 of the 17 SSIs (100%) were orthopedic and performed by three surgeons. Surgeon A performed 24 procedures with seven SSIs (rate = 29.2%). Surgeon B performed 171 procedures with five SSIs (rate = 2.9%) and Surgeon C performed 13 procedures with three SSIs (rate = 23.1%). The seven SSIs associated with Surgeon A used different operating room (OR) personnel, rooms, anti-
biotics, and durations. There were 0 deaths. The seven SSIs and nine controls were evaluated using a stepwise regression model. Using the variables for bone graft, hard-
ware, OR location, and number of people in the OR, the only significant variable was the number of people in the OR and the rate among cases and seven among controls. Logistic regression yielded an odds ratio of 1.8 (95% CI: 0.99:3.26).

**Conclusion.** SSIs occurred primarily after orthopedic procedures, and two of three indicated surgeons (A and B) were among the high risk surgeons. Surgeon C’s procedures were not unique and reflect a larger issue in how skin prep is performed across the country. We found a better prognosis for patients with an extravascular PVGI, without septic shock. Finally, PVGI treated with an antibiotic combination including rifampicin had a better outcome.

**Disclosures.** All authors: No reported disclosures.
