Abstract

Cervical precancer lesion can generally be seen in the transformation zone. Colposcopy allows us to see an image of enlarge precancer lesion in the transformation zone. The colpocopist should consider some important things to determine the appearance of low-grade lesion or high-grade lesion. Two important things are the description of abnormal epithelium and the description of abnormal blood vessels. The description of the abnormal epithelial seen after administration of acetic acid 3-5%, acetowhite looks faster and disappears slower. The “white” lesion is more concentrated like the color of shells, with clear border and surface contour. To find the abnormal blood vessels more clearly, we can use the green filter. High-grade lesion shows rough mosaic and rough punctuation or both. In addition, finding the cervical blood vessels can help us to determine high-grade lesion. By understanding the description of the epithelial cervix and abnormal blood vessels, we will easily distinguish high-grade lesions from low grade lesion.

Keywords: cervical precancer, colposcopy findings

INTRODUCTION

Colposcopy accompanied by directional biopsy is the gold standard to establish a diagnosis of cervical precancer lesions. Colposcopy is a microscope that can help us to visualize the cervix with a magnification of 6 to 40 times. To be able to correctly interpret the description of the colposcopy, we need a knowledge of histopathological change occurs in the epithelial and cervical stroma. Epithelial is a layer that is not colored, while stroma has a red color due to blood vessels contained in there. The red color is reflected back to the examiner. Thickness, structure and density of epithelium can affect reflected light. In the epithelial of the precancer lesions, there is an increase in thickness and changes in the structure that is reflected to the examiner instead of the red color of the cervical stroma, but we will see white color (especially after the administration of acetic acid). The white color with the strict boundary seen in the transformation zone is a pathognomonic finding in colposcopy to diagnose precancer lesion.

When acetic acid applied in the area of precancer lesion, the nucleoproteins that are precipitate in the precancer cells will obstruct the light, so that the light will be reflected and exhibit an acetowhite image. In low grade lesions, acetic acid will enter until the middle of the cervical epithelial, so that the white color will be slowly visible. While in high-grade lesion,
acetic acid administration will immediately show a clearer white color. ¹ The clearer white lesion, then the longer white color is seen, this gives a picture of a high-grade of lesions. ³

There are several agreements on the criteria that distinguish the extent of the high grade compare to low grade, such as acetowhite appearance after applied of acetic acid, firmly the border between the acetowhite area with the surrounding area, the blood vessel, and the description of atypical blood vessels. ⁴ To diagnose precancer lesion, the three main modalities which is cytology, colposcopy and histopathology should be interconnected. The abnormal cytology (pap smear) results will help the clinician to see and look for precancer lesions in the cervix.¹ Around 70% to 75% patients with the pap smear result of high-grade Intraepithelial lesion (HSIL) is a high-grade of precancer lesion (cervical intraepithelial neoplasia (CIN) 2-3), and about 1% to 4% is a cervical cancer. ⁵

DESCRIPTION COLPOSCOPY FINDING OF PRECANCER LESION

Acetowhite appearance (figure 1) are paramount in assessing the description of the colposcopy, as this relates to the change of normal cervical epithelial (metaplasia) to the precancer lesion. In addition, three images of colposcopy that need to be considered are margin, surface contours and patterns of atypical blood vessels.¹ ²

**Figure 1.** Acetowhite appearance. A. Normal, B. Metaplasia (yellow arrow) C. Precancer lesion (yellow arrow).

**Acetowhite appearance**

The depiction of a high-grade lesion after applied the acetic acid shows a thick acetowhite area, with clear/opaque white and a firmly border/edge.² For comparison, the normal cervical epithelial after applied the acetic acid does not exhibit white discoloration. This process occurs because in the normal cervical epithelial there is a high amount of glycogen and minimal amount of protein, whereas in the epithelial of a high-grade precancer lesion there are high amounts of protein (on cell membranes, nuclei and cytoplasm) but very little amount of glycogen. While in low-grade lesion have a lot of protein and glycogen, so when we applied the acetic acid shows the white color (acetowhite) is unclear and the iodine administration shows a faint yellow color (weak and unequal staining).¹
Acetowhite changes is dynamic changes with its peak seen after 60-90 seconds of acetic acid administration. High-grade lesion will retain the color acetowhite longer (2-4 minutes) but low-grade lesion will fade rapidly.\(^5\) Other modality to find precancer lesion is to perform Iodine test/ Schiller test. Iodine test, first introduced by Schiller in 1929, was used to exhibit a precancer lesion. A large squamous epithelium containing glycogen will be seen as brown color after iodine administration. Whereas in precancerous lesions containing keratin but less glycogen will give a yellow color post-administration of iodine.\(^1,2\)

The high-grade lesion is divided into two, based on the histopathology overview, the precancer lesion that exhibit dysplasia cells occupying until two-thirds of the cervical epithelial categorized as CIN 2. Meanwhile lesion that exhibit cell dysplasia occupy more than two-thirds are categorized as CIN 3.\(^6\) Bowring et al added the size of acetowhite area is a variable that needs to be assessed.\(^7\)

![Fig 3. A. Inner border sign. (Black arrow) B. Rigde sign (Black arrow). (source: Bornstein J, Bentley J, Bösze P, Girardi F, Haefner H, Menton M, et al. 2011 Colposcopic Terminology of the International Federation for Cervical Pathology and Colposcopy. Obstet Gynecol. 2012;120:166-72)\](image)

The new colposcopy terminology was compiled by the Committee of the International Federation of Cervical Pathology and colposcopying adding two markers (figure 3) for high-
grade lesion namely "inner border sign" and "Ridge sign." The Inner border sign is a strict border between the thin acetowhite region and the thick acetowhite area of the same lesion.8

**Margin/border and contour surfaces of precancer lesion**

In high-grade lesion, the outline of the margin/border shows a firm, regular and thicker than the surrounding epithelial.1 Different from irregular and unequivocal low-grade lesion.5,6 High-grade lesion can be seen inside a wider low-grade lesion, in the figure below, we find edges of the lesion show the internal border or demarcation more firmly.5

![Fig 4](source: Massad LS. High-Grade Squamous Intraepithelial Lesions. In: Apgar BS, Brotzman GL, Spitzer M, editors. Colposcopy Principles and Practice - An Integrated Textbook and Atlas. 2nd ed: Elservier; 2008. p. 231-60).

The contours of the acetowhite area surface of high-grade lesion show nodular, not slippery/flat contour.2 The Surface contour of the high-grade lesion is easier to detach from basal membrane, causing abrasion in the cervical epithelial. A high-grade lesion shows the contours of an easily peeled surface (peeling).5

**Vascular pattern and atypical blood vessel**

Vascular changes can be clearer by using green filters. In high-grade lesion, we can find a mosaic and a rough (coarse) punctation appearance.5 Abnormal vascular appearance such as punctation and mosaics are only meaningful when inside the acetowhite area.2 A picture of smooth (fine) punctation and mosaic can be found at low-grade lesion.3 When both of these vascular appearance are welded so that the capillary loops are in the middle of the mosaic image, it is called the umbilication.2
The smaller and smoother the mosaic picture (figure 5), it tends to be a low-grade lesion, while the wider and irregular mosaic appearance then tends to be a high-grade lesion. The farther intercapillary distance, then more rough the vascular pattern. The atypical blood vessels have their own characteristics and are associated with significant pathological changes in the cervical epithelial. Atypical vein is a terminal blood vessel that is described by the irregularities of the shape, calibre and density of blood vessels. The atypical blood vessels can be seen in cervical cancer. There are six forms of atypical blood vessels seen in the precancer lesion (network-like, red dotted, red spotted, branch like, linear, loop-like).

SCORING COLPOSCOPY FINDING

A large variety of appearance are shown by precancer lesion. The scoring is used to improve the objectivity of the colposcopic finding and reduce variations between the colposcopist. This will reduce subjectivity in assessing a high or low-grade lesion. Scoring should be easy to use in clinical practice, because the purpose of the actual scoring is to assist in the assessment of colposcopy examination whether the conditions are high-grade lesion or low-grade lesion.

Table 1. Reid scoring (source Tatti S, Bornstein J, Prendiville W. Colposcopy: A Global Perspective Introduction of the New IFCPC Colposcopy Terminology. Obstet Gynecol Clin N Am. 2013;40:235-50)

| Colposcopic Sign          | 0 Points                                      | 1 Point                          | 2 Points                               |
|---------------------------|-----------------------------------------------|----------------------------------|----------------------------------------|
| Margin                    | Condylomatous or micropapillary contour        | Regular lesions with smooth, straight outlines | Rolled, peeling edges                  |
| Indistinct borders        | Sharp peripheral margins                      | Internal borders between areas of differing appearance |
| Flocculated or feathered margins |                                  |                                  |                                        |
| Jagged, angular lesions   |                                               |                                  |                                        |
| Satellite lesions, acetowhite change that extends beyond the transformation zone |                                  |                                  |                                        |
| Color                     | Shiny, snow-white color                       | Shiny, grey-white                | Dull, oyster-gray                       |
| Indistinct acetowhite change, semitransparent rather than completely opaque | Intermediate white                   |                                  |                                        |
| Vessels                   | Uniform, fine caliber                         | Absence of surface vessels       | Individual vessels dilated, arranged in sharply demarcated, well-defined patterns |
| Randomly arranged patterns|                                               |                                  |                                        |
| Nondilated capillary loops|                                               |                                  |                                        |
| Ill-defined areas of fine punctation or mosaIC |                                  |                                  |                                        |
| Iodine staining           | Positive iodine uptake, producing a mahogany-brown color | Partial iodine uptake (variegated and tortoiseshell) | Yellow staining of a lesion, which is scored 3/6 |
| Yellow staining by an area that is recognizable as a low-grade lesion by above criteria (<2/6) |                                  |                                  | Mustard-yellow appearance               |
| Colposcopic score         | 0–2 = HPV or CIN 1 (low-grade disease)        | 3–4 = CIN 1 or CIN 2 (intermediate-grade disease) | 5–8 = CIN 2 or CIN 3 (high-grade disease) |

Colposcopy terminology that is included in major changes (high-grade lesion) by the Committee of the International Federation of Cervical Pathology and colposcopy are strict border, clear internal/demarcation edge, acetowhite obvious depiction of mosaics and rough punctuation, and rapid acetowhite changes. The scoring created by Richard Reid referred as Colposcopy Reid index consists of four finding of colposcopy. The index consists of four variables namely acetowhite color gradation, margin and surface contour lesion, vascular and iodine staining. Each variable has a value of 0-2. If the total score 5-8 will considered as high-grade lesion.
Table 2. Alternative scoring index. A. Coppleson, B. Swede C. Shafi-Nazeer. (Source : Sellors JW, Sankaranarayanan R (2003), Strander B, Ellstrom-Andersson A, Franzen S, Milsom I, Radberg T. (2005), Nazeer S, Shafi MI (2011).

As alternative, there is scoring by Coppleson, Swede and Shafi-Nazeer. The Coppleson consist of two criteria (insignificant and significant).\(^2\) The Swede’ score uses size of the lesions as one variable. This scoring has a total value of 0 – 10.\(^4\) If the total Swede’ score \(> 8\) then it has a specificity of 95% to assess a high-grade lesion.\(^7\) The Swede scoring differs from the previous scoring, which does not include the size of the lesions as an important predictor for high degree lesions.\(^10\) The Shafi-Nazeer scoring includes the clinical factors as a variable to determine high-grade lesion. Clinical factors such as age, cytological results (low grade – high grade) and smoking habit are the clinical factors included in this scoring. The picture of the colposcopy assessed on the scoring includes a description of lesions, surface contours, intercapillary distance/vascular pattern, and border area of acetowhite.\(^9\)
CONCLUSION

1. Colposcopy followed by directional biopsy is the gold standard to diagnose of cervical precancer lesions
2. Three main modalities to diagnose precancer lesions are cytology, colposcopy and histopathology should be interconnected
3. Criteria that distinguish the extent of the high grade compare to low grade are acetowhite appearance, demarcation line between the acetowhite area with the surrounding area, the blood vessel, and the description of atypical blood vessels
4. Various scoring is available to improve the objectivity of the colposcopic finding and reduce variations between the colposcopist
