Metal-mediated DNA base pairing of easily prepared 2-oxo-imidazole-4-carboxylate nucleotides

Metal-mediated DNA base pairing, consisting of two ligand-type artificial nucleobases and a bridging metal ion, has attracted increasing attention as an alternative base pairing mode to natural base pairing. In this study, we showed that a novel 2-oxo-imidazole-4-carboxylate (ImOC) nucleobase, which can be easily derived from a commercially available uridine analogue, forms stable CuII- and HgII-mediated base pairs within DNA duplexes. Quantitative association of three CuII ions was also demonstrated in a duplex containing consecutive ImOC–ImOC pairs. This study will provide a new design strategy for metal-responsive DNA materials.
Metal-mediated DNA base pairing of easily prepared 2-oxo-imidazole-4-carboxylate nucleotides†

Lingyun Hu, Yusuke Takezawa and Mitsuhiko Shionoya

Metal-mediated DNA base pairs, which consist of two ligand-type artificial nucleobases and a bridging metal ion, have attracted increasing attention in recent years as a different base pairing mode from natural base pairing. Metal-mediated base pairing has been extensively studied, not only for metal-dependent thermal stabilisation of duplexes, but also for metal assembly by DNA templates and construction of functional DNAs that can be controlled by metals. Here, we report the metal-mediated base pairing properties of a novel 2-oxo-imidazole-4-carboxylate (ImOC) nucleobase and a previously reported 2-oxo-imidazole-4-carboxamide (ImOA) nucleobase, both of which can be easily derived from a commercially available uridine analogue. The ImOC nucleobases were found to form stable ImOC–CuII–ImOC–CuII base pairs in the presence of the corresponding metal ions, leading to an increase in the duplex melting temperature by +20 °C and +11 °C, respectively. The ImOC bases did not react with other divalent metal ions and showed superior metal selectivity compared to similar nucleobase design reported so far. The ImOC–CuII–ImOC base pair was much more stable than mismatch pairs with other natural nucleobases, confirming the base pair specificity in the presence of CuII. Furthermore, we demonstrated the quantitative assembly of three CuII ions inside a DNA duplex with three consecutive ImOC–ImOC pairs, showing great potential of DNA-template based CuII nanoarray construction. The study of easily-prepared ImOC base pairs will provide a new design strategy for metal-responsive DNA materials.

Introduction

The high versatility and programming capabilities of DNA structures have served as a bridge from fundamental concepts to practicality in the field of DNA nanotechnology, which is a successful example of molecule-based bottom-up self-assembly processes. Much attention has been focused on the construction of modified DNA monomers to further enrich the diversity of DNA structure and function. In particular, a great deal of effort has been devoted to the development of artificial nucleobase pairs, which are increasingly being recognised as highly effective. Among them, metal-mediated base pairing, which consists of two ligand-type artificial nucleobases and a bridging metal ion, has attracted increasing interest due to its unique coordination binding mode. The newly introduced metal-mediated base pairs impart unique properties to the modified DNA, depending on the inherent nature of the metal. In addition to metal-dependent thermal stabilisation of duplexes, DNA-templated metal assembly, modulation of charge transfer, molecular sensing and metal-dependent control of DNAzymes and aptamers have been reported. Therefore, finding appropriate ligand-type nucleobases that can specifically and strongly bind to a certain metal ion and form metal-mediated base pairs is important to achieve these functions.

A variety of ligand-type artificial nucleobases have been developed so far by modifying simple ligand scaffolds such as pyridine, malto and pyrimidine. Among them, the imidazole ligand is one of the smallest scaffolds. It has been reported that most of the modified imidazole nucleobases form AgI-mediated base pairs by N–AgI–N coordination. For example, imidazole-4-carboxylate (ImI) nucleobases form a base pair via CuII- and AgI-mediated coordination, and the negatively charged carboxylates neutralise the positive charge of the bridging metal ion. The ImI–CuII–ImI pair is one of the most stabilising artificial base pairs developed so far, but ImI retains its bonding affinity for other metals such as NiII and CoII. Furthermore, we have successfully applied ImI–CuII–ImI pairing to the metal-dependent functional regulation of DNAzymes.

† Electronic supplementary information (ESI) available. See DOI: 10.1039/d2sc00926a
With these examples as a starting point, we sought to expand the structural diversity of imidazole-like scaffolds that can form metal-mediated base pairs. Based on imidazole-4-carboxylate (\(\text{Im}^\text{C}\)), a novel ligand-type nucleobase, 2-oxo-imidazole-4-carboxylate (\(\text{Im}^\text{OC}\)), was designed by modifying the C-2 position (Fig. 1). Unlike conventional examples, \(\text{Im}^\text{OC}\) nucleosides can be easily derived from commercially available nucleosides,\(^{54,55}\) reducing the need for laborious synthesis. The \(\text{Im}^\text{OC}\) nucleobase was predicted to have the following characteristics: (1) In contrast to the \(\text{Im}^\text{C}\) nucleobase, the N3 atom of \(\text{Im}^\text{OC}\) is protonated under neutral conditions.\(^{56}\) Since metal coordination requires deprotonation or amide–iminol tautomerisation, \(\text{Im}^\text{OC}\) was expected to show a metal binding affinity different from the \(\text{Im}^\text{C}\) nucleobase. (2) As the \(\text{Im}^\text{C}\) nucleoside has a 2-carbonyl group, it preferentially adopts an anti-conformation suitable for metal-mediated base pairing, as reported for the 2-oxo-imidazole-4-carboxamide (\(\text{Im}^\text{OA}\)) nucleoside.\(^{55}\) (3) The 2-carbonyl group may also function as a hydrogen bond acceptor for certain amino acids in DNA polymerases.\(^{57,58}\) Therefore, such a structure may be advantageous for future polymerase incorporation studies.

In this study, DNA duplexes containing 2-oxo-imidazole-4-carboxylate (\(\text{Im}^\text{OC}\)) and 2-oxo-imidazole-4-carboxamide (\(\text{Im}^\text{OA}\)) were synthesised and their ability to form metal-mediated base pairs was investigated. Heterologous base pairing of \(\text{Im}^\text{OC}\) with other natural or unnatural nucleobases was also analysed in the presence and absence of certain metal ions. Furthermore, we investigated the construction of consecutive metal-mediated base pairs and explored the possibility of one-dimensional metal assembly inside DNA duplexes.

**Results and discussion**

**Synthesis of DNA strands containing \(\text{Im}^\text{OC}\) or \(\text{Im}^\text{OA}\) nucleosides**

The synthetic route for DNA strands containing \(\text{Im}^\text{OC}\) or \(\text{Im}^\text{OA}\) nucleosides is shown in Scheme 1. The 2-oxo-imidazole-4-carboxylate nucleoside (2) was synthesised by ring contraction of commercially available 5-bromo-2'-deoxyuridine (1).\(^{54}\) Its protected derivative 3 was prepared by the reported procedure.\(^{55}\) Phosphoramidite 4 was then synthesised without the N3 protection because the 3'-NH group was found to be intact during DNA synthesis just like thymidine. The resulting phosphoramidite was immediately used for solid-phase DNA synthesis.

Since the 4'-substituent was protected as a methyl ester, the nucleobase moiety can be converted to either a carboxylate (\(\text{Im}^\text{OC}\)) or a carboxamide (\(\text{Im}^\text{OA}\)) depending on the deprotection conditions. To confirm this, we synthesised a trimer DNA strand with one unnatural nucleotide (5'-TAT-3') and deprotected it with sodium hydroxide or ammonia solution. The deprotected products were analysed by HPLC (Fig. S1†) and ESI mass spectrometry (Fig. S2†). When the trinucleotide was treated with 0.3 M NaOH aq. at 37°C, an almost complete conversion to the carboxylate \(\text{Im}^\text{OC}\) was observed. When incubated in 25% ammonia solution, the artificial nucleobase was converted to the desired amide \(\text{Im}^\text{OA}\) in over 90% yield. The strands containing \(\text{Im}^\text{OC}\) and \(\text{Im}^\text{OA}\) were easily isolated by reverse-phase HPLC.

To investigate the metal-mediated base-pairing properties of \(\text{Im}^\text{OC}\) and \(\text{Im}^\text{OA}\) nucleotides, 15-mer DNA strands containing one or three \(\text{Im}^\text{OC} / \text{Im}^\text{OA}\) nucleotides in the central position were synthesised (Table 1). All the strands were deprotected with NaOH or ammonia solution to produce \(\text{Im}^\text{OC}\) or \(\text{Im}^\text{OA}\) nucleobases, which were purified by HPLC (Fig. S3†). The DNA

Cu\textsuperscript{II}-mediated base pairing of Im\textsuperscript{OC} nucleobases

Metal-mediated base pairing was first examined in a duplex containing a single artificial base pair, Im\textsuperscript{OC}-Im\textsuperscript{OC} or Im\textsuperscript{OA}-Im\textsuperscript{OA}. Thermal melting analysis of duplexes 1-2 and 3-4 was performed in the absence and presence of various metal ions (1.0 equiv.), including first-row transition metal ions and square-planar Pd\textsuperscript{II} and Pt\textsuperscript{II} ions (Fig. 2, S4, and Table S1\textsuperscript{f}). In the absence of metal ions, the melting temperatures (T\textsubscript{m}) of the Im\textsuperscript{OC}-modified duplex 1-2 and Im\textsuperscript{OA}-modified duplex 3-4 were 23.0 °C and 34.5 °C, respectively. Both duplexes were significantly less stable than a fully matched duplex containing an A-T pair in the middle (T\textsubscript{m} = 44.2 °C),\textsuperscript{14} indicating that both Im\textsuperscript{OC}-Im\textsuperscript{OC} and Im\textsuperscript{OA}-Im\textsuperscript{OA} behave as mismatch pairs. The T\textsubscript{m} value of duplex 1-2 is about 12 °C lower than that of duplex 3-4. This may be due to the coulombic repulsion between the negatively charged carboxylates of the Im\textsuperscript{OC}-Im\textsuperscript{OC} base pair. A similar phenomenon was also observed in the DNA duplex containing a pair of imidazole-4-carboxylate nucleobases (Im\textsuperscript{C})\textsuperscript{15}, which showed a T\textsubscript{m} value (22.5 °C) similar to that of the Im\textsuperscript{OC}-containing duplex 1-2.\textsuperscript{15} Among the metal ions tested, only the Cu\textsuperscript{II} ion showed significant stabilisation of duplex 1-2 (T\textsubscript{m} = 43.3 °C, ΔT\textsubscript{m} = +20.3 °C). On the other hand, none of these metal ions caused a significant change in the melting profile of duplex 3-4 (−1 °C ≤ ΔT\textsubscript{m} ≤ +1 °C). The Cu\textsuperscript{II}-dependent stabilisation of duplex 1-2 suggests the Cu\textsuperscript{II}-mediated formation of the Im\textsuperscript{OC}_

Cu\textsuperscript{II}-Im\textsuperscript{OC} base pair, which crosslinks the duplex via metal coordination bonds.

Fig. 3a shows the melting curves of duplex 1-2 in the presence of various amounts of Cu\textsuperscript{II} ions. In the presence of 0.5 equiv. of Cu\textsuperscript{II} ions, a two-step transition was observed, indicating the presence of both metal-free and Cu\textsuperscript{II}-bound DNA duplexes. The addition of more than one equivalent of Cu\textsuperscript{II} did not cause any obvious change in the melting behaviour. In addition, Cu\textsuperscript{II}-dependent stabilisation was not observed in the fully matched duplex or in the duplex containing a T-T mismatch.\textsuperscript{35,36} These results proved that the metal-mediated base pair was formed by the binding of a single Cu\textsuperscript{II} ion, and also indicated that there is a high binding affinity between Im\textsuperscript{OC} and Cu\textsuperscript{II}. The stoichiometry of the Im\textsuperscript{OC}_

Cu\textsuperscript{II}-Im\textsuperscript{OC} base pair was further confirmed by ESI-TOF mass spectrometry (found: 1838.41 (z = 5); calcd. for [1·2 + Cu\textsuperscript{II} – 7H\textsuperscript{+}]: 1838.47; Fig. 3b and S5\textsuperscript{f}).

It is suggested that the Im\textsuperscript{OC}_

Cu\textsuperscript{II}-Im\textsuperscript{OC} pair is formed by the coordination of both the N3 atoms and the carboxylate groups in a square planar geometry. Cu\textsuperscript{II}-mediated base pairing with similar coordination structures has been reported with imidazole-4-carboxylate nucleobases (Im\textsuperscript{C})\textsuperscript{32} and with 6-carboxyapurines.\textsuperscript{39} The carboxylate group of the Im\textsuperscript{OC} nucleobases not only coordinates with the Cu\textsuperscript{II} ion, but also neutralises the positive charge of the metal, thus maintaining a neutral environment within the DNA duplex. However, in the case of the Im\textsuperscript{OA} nucleobase, the carboxamide group is a weak neutral ligand and cannot neutralise the resulting complex. This is the main reason why metal-mediated base pairing with Im\textsuperscript{OA} is unfavourable.

The circular dichroism (CD) spectra of duplex 1-2 were also measured in the absence and presence of Cu\textsuperscript{II} ions (Fig. 3c). The spectra showed Cotton effects characteristic of right-handed B-DNA, indicating that the introduction of the Im\textsuperscript{OC}_

Cu\textsuperscript{II}-Im\textsuperscript{OC} base pair did not alter the typical duplex structure. Due to the small size of the Im\textsuperscript{OC} base, the π-π stacking interaction with the neighbouring base pairs may be reduced, making the

\end{align*}
HgII-mediated base pairing of imOC/imOA nucleobases

HgII and AgI ions are often involved in metal-mediated base pairing in two-coordinate geometry, such as the classical T–HgII–T35,56 and C–AgI–C base pairs. Since the 2-oxo-imidazole ring is derived from uridine/thymine nucleobases, imOC and imOA were expected to form a metal-mediated base pair similar to T–HgII–T. To investigate this, we conducted melting analysis of duplexes 1–2 and 3–4 in the presence of HgII or AgI ions (Fig. 4, S6 and Table S2†). In these measurements, sodium chloride in the buffer solution was replaced by sodium nitrate to prevent precipitation of metal chlorides.

The addition of one equivalent of HgII ions markedly increased the stability of both imOC- and imOA-containing duplexes (ΔTm = +11.4 °C and +6.2 °C for duplexes 1–2 and 3–4, respectively). The addition of excess HgII did not stabilise the duplexes anymore (Fig. S7†). This suggests that the formation of imOC–HgII–imOC and imOA–HgII–imOA base pairs is mediated by a single HgII ion. The HgII-mediated base pairing was further confirmed by ESI-MS measurements of the imOC-containing duplex (found: 2342.26 (z = 4); calcd for [1–2 + HgII + K+ – 7H2O]: 2342.11; Fig. S8†) and the imOA containing one (found: 2332.08 (z = 4); calcd. for [3–4 + HgII – 6H2O]: 2332.13; Fig. S9†). ImOC and imOA are thought to form a linear complex with HgII via coordination of the deprotonated N3 atom, similar to the T–HgII–T base pair.51,64 It is noteworthy that in the case of imOC, the degree of HgII-dependent duplex stabilisation is comparable to that observed for the T–HgII–T base pair (ΔTm = +10.9 °C) under the same conditions.33

Notably, the addition of AgI did not stabilise the duplexes containing imOC and imOA. On the other hand, previous studies have shown that the duplex with an imidazole-4-carboxylate base pair (imC–imC) is stabilised by both HgII and AgI ions, with a slightly higher preference for AgI over HgII.35,56 These results indicate that imOC and imOA nucleobases improve the metal selectivity, which can be attributed to the protonated N3 atoms. Therefore, imOC and imOA bases are more suitable for the construction of complex molecular systems using multiple types of metal ions.

Heterologous base pairing of imOC with other natural and unnatural nucleobases

Apart from the homologous base pairing, base pairing between imOC- and other nucleobases was also examined to clarify the specificity. First, mismatch base pairing with four natural nucleobases was evaluated by duplex melting analysis (Fig. 5a and Table S3†). The Tm values of the duplexes with an imOC–N pair (N = A, T, C and G) were different, and the pyrimidine mismatches (imOC–T and imOC–C) were found to be less stable than the purine mismatches (imOC–A and imOC–G). This trend can be well explained by the fact that the size of the imOC purine pairs is comparable to that of the natural base pairs. Similar results were also obtained in previous studies examining imOA–N base pairing.35 The addition of one equivalent of CuII ions did not cause an obvious Tm change, indicating that imOC does not form CuII-mediated base pairs with natural nucleobases. It is important to note that the Tm value of the duplex containing imOC–CuII–imOC is higher than all other duplexes with an imOC–N pair. This result shows the specificity of the imOC–CuII–imOC base pair over pairing with natural nucleobases in the presence of CuII ions.

Next, we investigated the possibility of heterologous base pairing between imC and imOC in relation to the previously studied imC–CuII–imC base pair (Fig. 5b, S10 and Table S4†). As expected, the duplex melting analysis showed that the imC–
Cu^{II}–Im^{F} heterologous base pair was formed in the presence of Cu^{II} ions ($\Delta T_m = 26.1 ^\circ C$). The $\Delta T_m$ value was intermediate between those of the duplexes containing the Im^{OC}–Cu^{II}–Im^{OC} and Im^{F}–Cu^{II}–Im^{F} pairs. This result reflects the Cu^{II} binding affinity of Im^{OC} and Im^{F} described above.

DNA-templated metal assembly using Im^{OC} nucleobases

The construction of one-dimensional metal arrays using DNA as a template is one of the promising applications of metal-mediated base pairing. To investigate the possibility of DNA-templated metal assembly using Im^{OC} nucleobases, a 15-mer duplex with three consecutive Im^{OC}–Im^{OC} base pairs in the centre (duplex 5-6) was prepared.

Duplex melting experiments were conducted in the presence of different amounts of Cu^{II} ions (Fig. 6a). In the absence of Cu^{II} ions, duplex 5-6 was highly unstable, and the $T_m$ value could not be determined. As the amount of Cu^{II} ions increased, the melting curves gradually shifted. Further investigation of the possibility of heterologous base pairing in DNA duplexes. When 3 equiv. of Cu^{II} ions were added, the $T_m$ value was almost at its maximum ($T_m = 51.7 ^\circ C$). The melting curves were hardly changed by the addition of excess Cu^{II}. These results show that three base pairs of Im^{OC}–Cu^{II}–Im^{OC} are quantitatively formed in duplex 5-6. The $T_m$ value of duplex 5-6 with 3 equiv. of Cu^{II} is about 10 ^\circ C higher than that of duplex 1-2 with equimolar Cu^{II}. This indicates that the incorporation of multiple Im^{OC}–Cu^{II}–Im^{OC} base pairs enhances the duplex stability more efficiently.

The stoichiometric formation of the Im^{OC}–Cu^{III}–Im^{OC} base pairs was further examined by circular dichroism (CD) measurements at 4 ^\circ C (Fig. 6b). In contrast to the CD spectra of duplexes 1-2 and 3-4, the CD spectrum of duplex 5-6 showed a dramatic change upon Cu^{III} addition. As the amount of Cu^{III} ions increased, the CD intensity at 275 nm gradually decreased. The spectra changed linearly in the range of [Cu^{III}]/[5-6] = 0 to 3 and did not change with the addition of more than 3 equiv. of Cu^{III}. The result of the CD measurements were in excellent agreement with the behaviours of the melting curves, indicating that three Cu^{III} ions were bound within duplex 5-6. Such stoichiometry was also confirmed by ESI-MS measurements, where a duplex containing three Cu^{III} ions was mainly observed (found: 1860.92 (z = 5); calcd. for [5-6 + 3Cu^{III} – 11H]^+: 1860.84; Fig. 6c and S11†). These results suggest that the three Cu^{III} ions were quantitatively assembled inside the duplex due to the formation of the Im^{OC}–Cu^{III}–Im^{OC} base pairs. Thus, it was shown that a certain number of Cu^{III} ions can be aligned according to the number of Im^{OC} bases in the template DNA duplex.

Conclusions

In this study, we have shown that a novel 2-oxo-imidazole-4-carboxylate (Im^{OC}) nucleobase undergoes metal-mediated base pairing in DNA duplexes. The previously reported synthetic route for the corresponding phosphoramidite was shortened by removing one unnecessary protection step. The protected artificial nucleobase(s) in DNA oligomers can be easily converted to two types of nucleobases, Im^{OC} and the previously reported carboxamide (Im^{OA}), depending on the deprotection conditions. Other than the natural T and C bases, Im^{OC} and Im^{OA} are among the most easily prepared nucleobases that can form metal-mediated base pairs.

The metal-mediated base pairing of both nucleobases was studied by duplex melting analysis, CD spectrometry and mass spectrometry. It was found that the Im^{OC} homologous base pair forms stable metal-mediated base pairs with both Cu^{II} and Hg^{II} (i.e., Im^{OC}–Cu^{II}–Im^{OC} and Im^{OC}–Hg^{II}–Im^{OC}), and $\Delta T_m$ was +20.0 ^\circ C and +11.4 ^\circ C, respectively. In contrast, Im^{OA} showed only a slight increase in $T_m$ in the presence of Hg^{II} ($\Delta T_m = +6.2 ^\circ C$) due to the formation of the Im^{OA}–Hg^{II}–Im^{OA} pair. This difference in metal ion affinity is mainly due to the substituent at the 4-position, since the negative carboxylate group can form a stronger coordination bond with Cu^{II}. Probably due to the protonated N3 atom, Im^{OC} was found to exhibit superior metal selectivity compared to the structurally related imidazole-4-carboxylate (Im^{F}) nucleobase.

Further investigation of the possibility of heterologous base pairing in the absence and presence of metal ions revealed that the Im^{OC}–Cu^{III}–Im^{OC} base pair was more stable than heterologous base pairing with natural nucleobases (i.e. Im^{OC}–N), suggesting the specificity of metal-mediated homologous base pairing among the possible base pairing patterns. When paired with the previously reported Im^{C}, the resulting Im^{OC}–Cu^{III}–Im^{C}...
mediated base pairing with highly promising and will be probed in the future. Thus, metal-nanotechnology.

The stable ImOC–CuII–ImOC base pairing is expected to have applications such as the construction of DNA-templated metal arrays. In the preliminary experiments using a duplex containing three ImOC–ImOC base pairs, we succeeded in quantitatively assembling three CuII ions. Since the ImOC nucleoside can be prepared from a commercially available nucleoside by a short-step synthesis, ImOC oligomers are considered suitable for constructing one dimensional metal wires. In addition, the significant increase in duplex stability and high metal selectivity brought by the formation of the ImOC–CuII–ImOC base pair makes it a promising candidate for constructing metal-responsive DNA nanodevices and nanomachines. The newly introduced 2-oxo functional group is expected to play an important role in recognition by DNA polymerases. Applications such as enzymatic synthesis\textsuperscript{55,56} and PCR amplification\textsuperscript{57} are highly promising and will be probed in the future. Thus, metal-mediated base pairing with ImOC is believed to have high potential applications in DNA supramolecular chemistry and nanotechnology.

It has been reported that the $pK_{a2}$ of 1-methyl-2-oxoimidazole-4-carboxylate is greater than 13 (ref. 54). Therefore, the N3 atom of the ImOC nucleobase is considered to be protonated under neutral conditions.
