Metric inequalities for polygons

Adrian Dumitrescu

February 9, 2011

Abstract

Let \(A_1, A_2, \ldots, A_n\) be the vertices of a polygon with unit perimeter, that is \(\sum_{i=1}^{n} |A_iA_{i+1}| = 1\). We derive various tight estimates on the minimum and maximum values of the sum of pairwise distances, and respectively sum of pairwise squared distances among its vertices. In most cases such estimates on these sums in the literature were known only for convex polygons.

In the second part, we turn to a problem of Braß regarding the maximum perimeter of a simple \(n\)-gon (\(n\) odd) contained in a disk of unit radius. The problem was recently solved by Audet et al. [3], who gave an exact formula. Here we present an alternative simpler proof of this formula. We then examine what happens if the simplicity condition is dropped, and obtain an exact formula for the maximum perimeter in this case as well.

Keywords: Metric inequalities, polygon, perimeter, sum of distances.

1 Introduction

Let \(A_1, A_2, \ldots, A_n\) be the vertices of a possibly self-crossing polygon (i.e., closed polygonal chain) with unit perimeter in the Euclidean plane. Here the perimeter is \(\text{per}(A_1A_2\ldots A_n) = \sum_{i=1}^{n} |A_iA_{i+1}|\), where indices are taken modulo \(n\) (i.e., \(A_{n+1} = A_1\)). Let \(s(n)\) be the infimum of the sum of pairwise distances among the \(n\) vertices, and \(s_c(n)\) be the same infimum for the case of convex polygons:

\[s(n) = \inf_{\text{per}(A_1A_2\ldots A_n) = 1} \sum_{i<j} |A_iA_j|. \tag{1}\]

\[s_c(n) = \inf_{\text{per}(A_1A_2\ldots A_n) = 1, A_1A_2\ldots A_n \text{ convex}} \sum_{i<j} |A_iA_j|. \tag{2}\]

Larcher and Pillichshammer [14] proved that \(s_c(n)\) grows linearly in \(n\), and more precisely, that \(s_c(n) \geq \frac{n-1}{2}\). Alternative proofs were recently given by Aggarwal [1] and Lükö [15]. We have nearly equality, if \(A_1\) is close to \((0,0)\) and the other \(n-1\) vertices \(A_i\) (\(i > 1\)) are all close to \((\frac{1}{2},0)\). Hence \(s_c(n) = \frac{n-1}{2}\), as previously conjectured by Audet et al. [3]. Here we extend this result for arbitrary polygons and show that \(s(n)\) has a similar behavior.

**Theorem 1.** For every \(n \geq 3\), \(s(n) \geq \frac{n}{3}\). For \(n\) even equality holds; for \(n\) odd, \(s(n) \leq \frac{n+1}{4}\).

Let now $S(n)$ be the supremum of the sum of pairwise distances among the vertices, and $S_c(n)$ be the same supremum for the case of convex polygons:

\[
S(n) = \sup_{\text{per}(A_1A_2\ldots A_n)=1} \sum_{i<j} |A_iA_j|.
\]

\[
S_c(n) = \sup_{A_1A_2\ldots A_n\text{ convex}} \sum_{i<j} |A_iA_j|.
\]

Larcher and Pillichshammer [13] considered the following generalization of the sum of pairwise distances, for which they proved:

**Theorem A.** [13, Theorem 1] Let $f: [0,1/2] \rightarrow \mathbb{R}^+_0$ be a function such that $f(x)/x \leq 2f(1/2)$. Then for any $n \geq 3$ and for any convex polygon with $n$ vertices and unit perimeter we have

\[
\sum_{i<j} f(|A_iA_j|) \leq f\left(\frac{1}{2}\right) \frac{n}{2} \left\lfloor \frac{n}{2} \right\rfloor.
\]

This bound is best possible.

By taking $f(x) = x$, it follows from Theorem A (as proved in [13]) that $S_c(n)$ is quadratic in $n$, and more precisely, that $S_c(n) \leq \frac{1}{2} \left\lfloor \frac{n}{2} \right\rfloor \left\lceil \frac{n}{2} \right\rceil$, as previously conjectured by Audet et al. [3]. An alternative proof was given recently by Aggarwal [1] based on classical results of Altman [2] for convex polygons. We have nearly equality if $A_1, \ldots, A_{\lfloor n/2 \rfloor}$ are close to $(0,0)$ and $A_{\lfloor n/2 \rfloor}+1, \ldots, A_n$ are close to $(\frac{1}{2},0)$; see [3]. Hence the above upper bound is best possible, thus $S_c(n) = \frac{1}{2} \left\lfloor \frac{n}{2} \right\rfloor \left\lceil \frac{n}{2} \right\rceil$. Here we show that convexity can be dropped and the same inequality holds for arbitrary (not necessarily convex, and possibly self-crossing) polygons: that is, $S(n) \leq \frac{1}{2} \left\lfloor \frac{n}{2} \right\rfloor \left\lceil \frac{n}{2} \right\rceil$. This result has been also obtained recently by Lükö [15]. (Since both his proof as well as ours rely on the triangle inequality, both work in any metric space.)

**Theorem 2.** For every $n \geq 3$,

\[
S(n) = \frac{1}{2} \left\lfloor \frac{n}{2} \right\rfloor \left\lceil \frac{n}{2} \right\rceil.
\]

Next we consider the sum of squared distances. Let now $t(n)$ be the infimum of the sum of pairwise squared distances among the vertices, and $t_c(n)$ be the same infimum for the case of convex polygons:

\[
t(n) = \inf_{\text{per}(A_1A_2\ldots A_n)=1} \sum_{i<j} |A_iA_j|^2.
\]

\[
t_c(n) = \inf_{A_1A_2\ldots A_n\text{ convex}} \sum_{i<j} |A_iA_j|^2.
\]

For convex polygons, it is known that $t_c(n)$ is linear in $n$. The current best lower bound, $t_c(n) \geq \frac{2n}{3\pi^2}$, is due to Jamuszewski [11]. From the other direction, placing $A_1$ near $(0,0)$, $A_2$ near $(\frac{1}{2},0)$ and the other $n-2$ points near the midpoint of $A_1A_2$, all in convex position, shows that $t_c(n) \leq \frac{2}{9} [16]$. (An earlier version of this/current paper [arXiv:0912.3929] reports a lower bound $t_c(n) \geq \frac{5n-1}{16}$. However, its proof had an error.)
For arbitrary polygons, it is easy to make a construction for which this sum converges to 1/4 as \( n \) tends to infinity. For even \( n \), place the odd index vertices at \((0,0)\), and the even index vertices at \((\frac{1}{n},0)\). Then \( Z = \frac{n^2}{4} \cdot \frac{1}{n^2} = \frac{1}{4} \). For odd \( n \), place the odd index vertices at \((0,0)\), and the even index vertices at \((\frac{1}{n-1},0)\). Then \( Z = \frac{n^2-1}{4} \cdot \frac{1}{(n-1)^2} = \frac{1}{4} \cdot \frac{n+1}{n-1} \to \frac{1}{4} \). Here we obtain a lower bound that is off by a factor of 2.

**Theorem 3.** For every \( n \geq 3 \),
\[
\frac{1}{8} \leq t(n) \leq \frac{1}{4}.
\]

Finally, let \( T(n) \) be the supremum of the sum of pairwise squared distances among the vertices, and \( T_c(n) \) be the same supremum for the case of convex polygons:
\[
T(n) = \sup_{\text{per}(A_1A_2\ldots A_n)=1} \sum_{i<j} |A_iA_j|^2. 
\]
\[
T_c(n) = \sup_{\text{per}(A_1A_2\ldots A_n)\text{ convex}} \sum_{i<j} |A_iA_j|^2. 
\]

By taking \( f(x) = x^2 \), it follows from Theorem A (see [13]) that \( T_c(n) \) is quadratic in \( n \), and more precisely, that \( T_c(n) \leq \frac{1}{4} \left\lfloor \frac{n}{2} \right\rfloor \left\lceil \frac{n}{2} \right\rceil \). An easy construction (also mentioned earlier in connection to \( S_c(n) \)) with vertices \( A_1, \ldots, A_{n/2} \) near \((0,0)\) and \( A_{n/2+1}, \ldots, A_n \) near \((1/2,0)\), all in convex position, shows that the above inequality is tight: \( T_c(n) = \frac{1}{4} \left\lfloor \frac{n}{2} \right\rfloor \left\lceil \frac{n}{2} \right\rceil \). Again, here we show that convexity can be dropped and the same inequality holds for arbitrary (not necessarily convex, and possibly self-crossing) polygons. That is, \( T(n) \leq \frac{1}{4} \left\lfloor \frac{n}{2} \right\rfloor \left\lceil \frac{n}{2} \right\rceil \), and we obtain:

**Theorem 4.** For every \( n \geq 3 \),
\[
T(n) = \frac{1}{4} \left\lfloor \frac{n}{2} \right\rfloor \left\lceil \frac{n}{2} \right\rceil.
\]

In the second part of the paper we turn to the following problem [8, p. 437] posed by Braß: For \( n \geq 5 \) odd, what is the maximum perimeter of a simple \( n \)-gon (\( n \) odd) contained in a disk of unit radius? The problem can be traced back to the collection of open problems in [7] (Problem 4, p. 449). A solution was recently found by Audet et al. [5] (Theorem 5 below), and another more general solution was offered by Langi [12]. Here we give yet another alternative solution. As noted in [7, 8], for even \( n \), one can come arbitrarily close to the trivial upper bound \( 2n \) by a simple polygon whose sides go back and forth near a diameter of the disk, but for odd \( n \) this construction does not work. Let \( \Omega \) be a disk of unit radius, and let
\[
F(n) = \sup_{\{A_1, A_2, \ldots, A_n\} \subset \Omega} \text{per}(A_1A_2 \ldots A_n).
\]

So trivially, \( F(n) = 2n \), for even \( n \). Fortunately, an exact formula for \( F(n) \) can be also determined for odd \( n \):

**Theorem 5.** [5]. For every \( n \geq 3 \) odd,
\[
F(n) = \frac{\sqrt{8(n-2)^2 - 2 + 2\sqrt{1 + 8(n-2)^2}} \cdot \left( \sqrt{1 + 8(n-2)^2} + 3 \right)}{4(n-2)}.
\]
A natural question is: What happens if the simplicity condition is dropped? As before (for simple polygons) for even \( n \), one can come arbitrarily close to the trivial upper bound \( 2^n \); however, for odd \( n \), the construction described previously (with the sides which go back and forth near a diameter of the disk) still does not work. Let

\[
G(n) = \sup_{\{A_1, A_2, \ldots, A_n\} \subset \Omega} \per(A_1 A_2 \ldots A_n). \tag{11}
\]

Clearly, \( G(n) \geq F(n) \) holds, so \( G(n) = 2^n \), for even \( n \). For odd \( n \), we determine an exact formula for \( G(n) \) as well:

**Theorem 6.** For every \( n \geq 3 \) odd,

\[
G(n) = 2n \cos \frac{\pi}{2n}. \tag{12}
\]

**Notation.** Throughout the paper, let \( P \) be a polygon with \( n \) vertices and unit perimeter, and \( V(P) = \{A_1, A_2, \ldots, A_n\} \) denote its vertex set. Let \( \ell(s) \) denote the line containing a segment \( s \). Let \( x(p) \) and \( y(p) \) stand for the \( x \)- and \( y \)-coordinates of a point \( p \). For brevity we denote the set \( \{1, 2, \ldots, n\} \) by \([n]\).

**Related problems and results.** Various extremal problems on the sum of distances and respectively squares of distances among \( n \) points in \( \mathbb{R}^d \) have been raised over time. For instance, more than 30 years ago, Witsenhausen [22] has conjectured that the maximum sum of squared distances among \( n \) points in \( \mathbb{R}^d \), whose pairwise distances are each at most 1 is maximized when the points are distributed as evenly as possible among the \( d + 1 \) vertices of a regular simplex of edge-length 1. He also proved that this maximum is at most \( \frac{d}{2(d+1)} n^2 \), which verified the conjecture at least when \( n \) is a multiple of \( d + 1 \). The conjecture has been proved for the plane by Pillichshammer [15], and subsequently in higher dimensions by Benassi and Malagoli [6]. See also [1, 3, 4, 5, 9, 10, 11, 16, 17, 18, 19] for related questions on the sum of pairwise distances. In the spirit of Theorems 5 and 6 a mathematical puzzle from Winkler’s collection [21, p. 114] asks for the minimum area of a simple polygon with an odd number of sides, each of unit length.

## 2 Sum of distances: proofs of Theorems 1 and 2

**Proof of Theorem 1.** Let \( p \in V(P) \) be an arbitrary vertex of \( P \), and let \( Z(p) = \sum_{q \in V(P)} |pq| \) be the sum of distances from \( p \) to the other vertices. The sum of pairwise distances \( Z \) satisfies \( 2Z = \sum_{p \in V(P)} Z(p) \). By the triangle inequality, for any \( i \in [n] \), we have

\[
|pA_i| + |pA_{i+1}| \geq |A_i A_{i+1}|.
\]

By summing over \( i \in [n] \), we get

\[
2Z(p) \geq \sum_{i=1}^{n} |A_i A_{i+1}| = 1.
\]

By summing over \( p \in V(P) \), we get \( 4Z \geq n \), or \( Z \geq n/4 \), as required.

To see that this inequality is almost tight, construct a non-convex polygon as follows: For even \( n \), place the odd index vertices at \((0, 0)\), and the even index vertices at \(\left(\frac{1}{n}, 0\right)\). Then \( Z = \frac{n^2}{4} \cdot \frac{1}{n} = \frac{n}{4} \).
For odd \( n \), place the odd index vertices at \((0, 0)\), and the even index vertices at \((\frac{1}{n-1}, 0)\). Then \( Z = \frac{n^2 - 1}{4} \cdot \frac{1}{n-1} = \frac{n+1}{4} \).

The following simple fact is needed in the proofs of Theorems 2 and 4.

**Lemma 1.** Given an arbitrary polygon \( P = A_1 A_2 \ldots A_n \), let \( Q = A_{i_1} A_{i_2} \ldots A_{i_k} \), where \( i_1 < i_2 < \ldots < i_k \), \( k \geq 3 \), be a sub-polygon of it. Then \( \text{per}(Q) \leq \text{per}(P) \).

**Proof.** By the triangle inequality, for any \( j \in [k] \), we have

\[
|A_{i_j} A_{i_{j+1}}| \leq \sum_{r=i_j}^{i_{j+1}-1} |A_r A_{r+1}|.
\]

By adding up the above inequality over all \( j \in [k] \), yields \( \text{per}(Q) \leq \text{per}(P) \), as required.

**Proof of Theorem 2.** (Sketch.) The proof is identical to that given by Larcher and Pillichshammer [14] for the convex case, and we refer the reader to their paper for details. A set of quadrilaterals \( \{Q_{ij}\} \) and a set of triangles \( \{R_i\} \) are defined [14] so that the edges of the quadrilaterals \( Q_{ij} \) and the triangles \( R_i \) form a partition of the edge set \( \{A_i A_j \mid i < j\} \) (each edge appears exactly once). By Lemma 1 one has \( \text{per}(Q_{ij}) \leq 1 \), and \( \text{per}(R_i) \leq 1 \), for the quadrilaterals \( Q_{ij} \) and for the triangles \( R_i \) defined in their proof. By adding up the perimeters of these polygons, it follows that the overall sum is bounded as \( S(n) \leq \frac{1}{2} \left\lfloor \frac{n}{2} \right\rfloor \left\lceil \frac{n}{2} \right\rceil \).

From the other direction, we clearly have \( S(n) \geq S_c(n) = \frac{1}{2} \left\lfloor \frac{n}{2} \right\rfloor \left\lceil \frac{n}{2} \right\rceil \), and the equality \( S(n) = \frac{1}{2} \left\lfloor \frac{n}{2} \right\rfloor \left\lceil \frac{n}{2} \right\rceil \) is proved.

### 3 Sum of squared distances: proofs of Theorems 3 and 4

We will need the following simple inequality:

**Lemma 2.** Let \( AB \) be a segment of length \( a \), and \( O \) be any point in the plane. Then

\[
OA^2 + OB^2 \geq \frac{a^2}{2} + 2y^2,
\]

where \( y \) is the distance from \( O \) to the line \( \ell(AB) \) determined by \( A \) and \( B \). In particular, \( OA^2 + OB^2 \geq \frac{a^2}{2} \).

**Proof.** Let \( M \) be the projection of \( O \) onto \( \ell(AB) \), and write \( a_1 = MA \), and \( a_2 = MB \). Clearly,

\[
OA^2 + OB^2 = a_1^2 + y^2 + a_2^2 + y^2 \geq \frac{a^2}{2} + 2y^2,
\]

as desired.

**Proof of Theorem 3.** The proof follows the same line of argument as that of Theorem 1. Let \( p \in V(P) \) be an arbitrary vertex of \( P \), and let \( Z(p) = \sum_{q \in V(P)} |pq|^2 \) be the sum of squared distances from \( p \) to the other vertices. The sum of squared pairwise distances \( Z \) satisfies \( 2Z = \sum_{p \in V(P)} Z(p) \). By Lemma 2 for any \( i \in [n] \), we have

\[
|pA_i|^2 + |pA_{i+1}|^2 \geq \frac{|A_i A_{i+1}|^2}{2}.
\]
By summing over \( i \in [n] \), we get
\[
2Z(p) \geq \frac{1}{2} \sum_{i=1}^{n} |A_i A_{i+1}|^2.
\]
The Cauchy-Schwarz inequality yields
\[
\sum_{i=1}^{n} |A_i A_{i+1}|^2 \geq \frac{1}{n} \left( \sum_{i=1}^{n} |A_i A_{i+1}| \right)^2 = \frac{1}{n}.
\]
Hence \( 4Z(p) \geq \frac{1}{n} \) for any \( p \in V(P) \). Summing up this inequality over all \( p \in V(P) \) yields
\[
8Z = 4 \sum_{p \in V(P)} Z(p) \geq \sum_{i=1}^{n} \frac{1}{n} = 1,
\]
so \( Z \geq 1/8 \), as required. \( \square \)

**Remark.** Interestingly enough, besides the construction mentioned in the Introduction (with two groups of vertices, \( [n/2] \) near \((0,0)\) and \([n/2]\) near \((\frac{1}{n},0)\)), there is yet another construction for which the sum of the squares of the distances is at most \( 1/4 \) in the limit. For odd \( n \), consider \( n \) points evenly distributed on a circle of radius \( r = 1/(2n \cos \frac{\pi}{2n}) \), and labeled from 1 to \( n \), say in clockwise order. The polygon \( P \) is the thrackle which connects the point labeled \( i \) with the point labeled \( i + \frac{n-1}{2} \) (as usually the indexes are taken modulo \( n \)). It is easy to verify that \( P \) has unit perimeter (see also Theorem 6). Write \( Z = \sum_{i<j} |A_i A_j|^2 \). We have
\[
Z = n \sum_{i=1}^{(n-1)/2} 4r^2 \sin^2 \frac{i\pi}{n} = 4nr^2 \left( \sum_{i=1}^{(n-1)/2} \sin^2 \frac{i\pi}{n} \right).
\]
Setting \( k = \frac{n-1}{2} \) and \( \alpha = \frac{\pi}{n} \) in the trigonometric identity \[20\] p. 64]
\[
\sum_{i=1}^{k} \sin^2 i\alpha = \frac{k+1}{2} - \frac{\sin[(k+1)\alpha] \cdot \cos[k\alpha]}{2 \sin \alpha}
\]
yields
\[
\sum_{i=1}^{(n-1)/2} \sin^2 \frac{i\pi}{n} = \frac{n+1}{4} - \frac{1}{4} = \frac{n}{4} \implies Z = 4nr^2 \cdot \frac{n}{4} = \frac{n^2}{4} \cdot \frac{1}{\cos^2 \frac{\pi}{2n}} = \frac{1}{4} \cdot \frac{1}{\cos^2 \frac{\pi}{2n}} \xrightarrow{n \to \infty} \frac{1}{4}.
\]
For even \( n \), duplicate one point in the above construction, and obtain a similar estimate.

**Proof of Theorem 4** (Sketch.) We only need to observe that the proof given by Larcher and Pillichshammer [13] for the convex case, [13, Theorem 1], can be extended for arbitrary polygons. We refer the reader to their paper for the missing details; see also [14] for a simpler proof of a slightly weaker upper bound, \( n^2/16 \). A set of quadrilaterals \( \{Q_{ij}\} \) and a set of triangles \( \{R_i\} \) are defined [13] so that the edges of the quadrilaterals \( Q_{ij} \) and the triangles \( R_i \) form a partition of the edge set \( \{A_i A_j \mid i < j\} \) (each edge appears exactly once). By Lemma 1 one has \( \text{per}(Q_{ij}) \leq 1 \), and
per(\(R_i\)) \leq 1$, for the quadrilaterals \(Q_{ij}\) and for the triangles \(R_i\) defined in their proof. Moreover, the proof of Lemma 1 in [13] continues to hold without the convexity assumption. By this lemma it follows that the sum of the squares of the edges of each such quadrilateral or triangle (along their perimeters) is at most 1/2. Similarly to the proof of Theorem 2, by adding up the sums of the squares of the edges of all these quadrilaterals and triangles, it follows that the overall sum is bounded as \(T(n) \leq \frac{1}{4} \left\lfloor \frac{n}{2} \right\rfloor \left\lceil \frac{n}{2} \right\rceil\).

From the other direction, we clearly have \(T(n) \geq T_\sigma(n) = \frac{1}{4} \left\lfloor \frac{n}{2} \right\rfloor \left\lceil \frac{n}{2} \right\rceil\), and the proof of Theorem 4 is complete. \(\square\)

4 Odd polygons: proofs of Theorems 5 and 6

**Proof of Theorem 5** For \(n = 3\) it is easily seen that the extremal polygon is an equilateral triangle of side \(\sqrt{3}\). Let \(a = a(n) = \sqrt{1 + 8(n - 2)^2}\) and let \(H(n)\) be the right hand side of (10). Then \(H(n)\) can be also written as

\[
H(n) = \frac{[(a + 1)^2 - 4]^{1/2}(a + 3)}{4(n - 2)}.
\]

Clearly, we have \(a \geq 2\sqrt{2}(n - 2) \geq 2\sqrt{2} \geq 3/2\), hence \((a + 1)^2 - 4 = a^2 + 2a - 3 \geq a^2\), and consequently \([(a + 1)^2 - 4]^{1/2} \geq a\). We show that this implies the inequality \(H(n) \geq 2(n - 2) + \frac{3\sqrt{2}}{2}\):

\[
H(n) \geq \frac{a(a + 3)}{4(n - 2)} \geq \frac{2\sqrt{2}(n - 2)}{4(n - 2)} \left(2\sqrt{2}(n - 2) + 3\right) = \frac{2\sqrt{2}(n - 2)}{2} = \frac{2(n - 2)}{2} + \frac{3\sqrt{2}}{2}.
\]

Let \(o\) be the center of \(\Omega\), and let \(P\) be an extremal (limit) polygon. Note that \(P\) may have overlapping edges but is otherwise non-crossing. We will show that \(P\) is unique and \(\text{per}(P) = H(n)\). We start with the upper bound \(\text{per}(P) \leq H(n)\). Let \(BC\) be a longest side of \(P\) of length \(|BC| = z \leq 2\). We can assume that \(BC\) is horizontal. Label each side \(A_i A_{i+1}\) by 1 or 0 depending on whether it goes from left to right, or from right to left in the \(x\)-direction (vertical sides are labeled arbitrarily). Since \(n\) is odd, we can find two consecutive sides of \(P\) with the same label, say 1: they form a (weakly) \(x\)-monotone path, \(\sigma\), of two edges. By relabeling the vertices (if necessary), we can assume that this path consists of the edges \(A_1 A_2\) and \(A_2 A_3\): \(\sigma = A_1 A_2 A_3\). Let \(L_1 = |\sigma| = |A_1 A_2| + |A_2 A_3|\), and let \(L_2\) be the total edge length of the other \(n - 2\) edges, so that \(\text{per}(P) = L_1 + L_2 \leq |\sigma| + (n - 2)z\).

Since \(z \leq 2\) we can write \(z = 2\sin \alpha\), for some \(\alpha \in [0, \pi/2]\). We first note that if \(z \leq \sqrt{3}\) the upper bound \(\text{per}(P) \leq H(n)\) follows immediately. Indeed: (i) for \(n = 5\), \(\text{per}(P) \leq 5 \cdot \sqrt{3} = 8.66\ldots \leq H(5) = 8.87\ldots \) and we are done; (ii) for \(n = 7\), \(\text{per}(P) \leq 7 \cdot \sqrt{3} = 12.12\ldots \leq H(7) = 12.92\ldots\) and we are done; (iii) for \(n \geq 9\), by (14), \(\text{per}(P) \leq n\sqrt{3} \leq 2(n - 2) + \frac{3\sqrt{2}}{2} \leq H(n)\), and we are also done. Therefore we can assume that \(z \geq \sqrt{3} = 2\sqrt{3}/2\), hence \(z = 2\sin \alpha\), for some \(\alpha \in [\pi/3, \pi/2]\).

**Lemma 3.** If \(z = 2\sin \alpha\), for some \(\alpha \in [\pi/3, \pi/2]\), then \(L_1 \leq 4\cos \frac{\alpha}{2}\).

**Proof.** Since the path \(\sigma = A_1 A_2 A_3\) is \(x\)-monotone and the polygon \(P\) is non-crossing, the vertical segments extended from interior points of \(BC\) meet the path on the same side of \(BC\), if at all. Assume without loss of generality that \(\sigma\) lies above \(BC\) in this sense. See Fig. 4(left and center) for two examples.
Consider for a moment the case when $BC$ is a right sub-segment of the horizontal diameter $\Delta$ of $\Omega$; see Fig. 1(right). Let $v$ be the length of the vertical chord incident to $B$. We have

$$v = 2\sqrt{1 - x^2} = 2\sqrt{1 - (z - 1)^2} = 2\sqrt{1 - (2\sin \alpha - 1)^2} = 4\sqrt{\sin \alpha - \sin^2 \alpha}.$$ 

We next verify that for $\alpha \in \left[\frac{\pi}{3}, \frac{\pi}{2}\right]$ we have

$$z + v < 4 \cos \frac{\alpha}{2}, \quad (15)$$

or equivalently,

$$\sin \alpha + 2\sqrt{\sin \alpha - \sin^2 \alpha} < 2 \cos \frac{\alpha}{2}. \quad (16)$$

Observe that both $f(\alpha) = \sin \alpha + 2\sqrt{\sin \alpha - \sin^2 \alpha}$ and $g(\alpha) = 2 \cos \frac{\alpha}{2}$ are decreasing functions on the interval $\left[\frac{\pi}{3}, \frac{\pi}{2}\right]$. Partition the interval $\left[\frac{\pi}{3}, \frac{\pi}{2}\right]$ into two interior-disjoint intervals:

$$\left[\frac{\pi}{3}, \frac{\pi}{2}\right] = [\alpha_1, \beta_1] \cup [\alpha_2, \beta_2],$$

where $\alpha_1 = \pi/3$, $\beta_1 = \alpha_2 = 5\pi/12$, and $\beta_2 = \pi/2$. It is enough to check that $f(\alpha_i) < g(\beta_i)$, for $i = 1, 2$: $f(\alpha_1) = 1.547\ldots < g(\beta_1) = 1.586\ldots$, and $f(\alpha_2) = 1.328\ldots < g(\beta_2) = 1.414\ldots$. We have thereby verified (16).

According to whether the slopes of $A_1A_2$ and $A_2A_3$ are $\geq 0$ or $\leq 0$, we say that the path $\sigma = A_1A_2A_3$ is of type $++$, $+-$, $-+$, or $--$ (zero slopes are labeled arbitrarily). For example, $\sigma$ in Fig. 1(left) is of type $-+$, while $\sigma$ in Fig. 1(center) is of type $-+$. We distinguish three cases:

**Case 1:** The path $A_1A_2A_3$ is of type $-+$, as in Fig. 1(center) or in Fig. 2(left). If $A_2$ lies below $\ell(BC)$, then $|A_1A_2| \leq v$ and obviously $|A_2A_3| \leq z$, and by (15), the inequality claimed in the lemma follows. Assume now that $A_2$ lies above $\ell(BC)$ and refer to Fig. 2. By symmetry we can assume that $x(o) \leq x(A_2)$. Let $MN$ be the vertical chord through $A_2$, and $Q = \ell(BC) \cap \ell(MN)$. Assume that $MN$ subtends a center angle $2\beta$, for some $\beta \in [0, \pi/2]$. For a fixed $x(A_2)$, the length $|\sigma|$ is maximized when $A_2 = Q$, $A_3 = M$, and $A_1 \in \partial \Omega$. Observe that the width and height of the rectangle with opposite vertices $o$ and $Q$ are $\cos \beta$ and $\cos \alpha$, respectively. Note that $|A_2A_3| = \cos \alpha + \sin \beta$. By the triangle inequality (used twice) we have

$$|A_1A_2| \leq |A_1o| + |oQ| \leq |A_1o| + \cos \alpha + \cos \beta = 1 + \cos \alpha + \cos \beta.$$
Note also the standard trigonometric inequality \( \cos \beta + \sin \beta \leq \sqrt{2} \). Putting these together we obtain

\[
|\sigma| = |A_1A_2| + |A_2A_3| \leq (1 + \cos \alpha + \cos \beta) + (\cos \alpha + \sin \beta)
\]

\[
= 1 + 2 \cos \alpha + (\cos \beta + \sin \beta) \leq 1 + \sqrt{2} + 2 \cos \alpha. \tag{17}
\]

Since \( \cos \alpha = 2 \cos^2 \frac{\alpha}{2} - 1 \), it remains to verify that \( 1 + \sqrt{2} + 2 \cos^2 \frac{\alpha}{2} - 2 \leq 4 \cos \frac{\alpha}{2} \). Make the substitution \( t = \cos \frac{\alpha}{2} \); then \( t \in [\cos \pi/4, \cos \pi/3] = [\sqrt{2}/2, \sqrt{3}/2] \), and we need to verify that

\[
1 + \sqrt{2} + 4t^2 - 2 \leq 4t,
\]

or equivalently,

\[
(2t - 1)^2 \leq 2 - \sqrt{2}, \quad \text{for} \quad t \in [\sqrt{2}/2, \sqrt{3}/2]. \tag{18}
\]

It is easy to see that for the above range of \( t \) we have

\[
(2t - 1)^2 \leq (2\sqrt{3}/2 - 1)^2 = (\sqrt{3} - 1)^2 \leq 2 - \sqrt{2},
\]

as required.

**Case 2:** The path \( A_1A_2A_3 \) is of type +−, as in Fig. 1(left). If \( x(A_2) \leq x(B) \) (the other case when \( x(A_2) \geq x(C) \) is symmetric), then \( |A_1A_2| \leq v \) and \( |A_2A_3| \leq z \), and inequality (15) concludes the proof. Otherwise, replace \( A_1A_2A_3 \) by a longer path as follows. Move \( A_1 \) on \( \ell(A_1A_2) \) away from \( A_2 \) to the intersection point of this line with the circle \( \partial \Omega \) or \( BC \), whichever comes first. In the latter case, move \( A_1 \) left on \( \ell(BC) \) to the intersection point of \( \partial \Omega \) and \( \ell(BC) \) (a strict increase in length follows from the fact that \( \sigma \) is \( x \)-monotone). Proceed similarly with \( A_3 \) by extending \( A_2A_3 \). Now move \( A_2 \) upward to the circle \( \partial \Omega \) while increasing \( |\sigma| \). We now have a path \( A_1A_2A_3 \) of type +− with all three points \( A_1, A_2, A_3 \) on the circle. Move \( BC \) downward until it hits \( \partial \Omega \), and then rotate it around the endpoint on \( \partial \Omega \); so now both endpoints \( B \) and \( C \) lie on the circle, and \( z = |BC| \) is unchanged. Unless \( A_1 = B \) and \( A_3 = C \), further increase \( |\sigma| \) while keeping \( z \) fixed by moving the points \( A_1 \) and \( A_3 \) on the circle towards \( B \) and respectively \( C \). In such a configuration, the chord \( BC \) subtends an angle of \( 2\alpha \) from the center \( o \). Hence for a fixed \( z \), \( L_1 \) is maximized when the triangle \( \Delta A_1A_2A_3 \) is isosceles with \( |A_2A_1| = |A_2A_3| \). Indeed, \( L_1 = 2(\sin \beta + \sin \gamma) \), where \( 2(\alpha + \beta + \gamma) = 2\pi \), thus

\[
L_1 = 2(\sin \beta + \sin \gamma) = 4 \sin \frac{\beta + \gamma}{2} \cos \frac{\beta - \gamma}{2} \leq 4 \sin \frac{\beta + \gamma}{2} = 4 \cos \frac{\alpha}{2},
\]
Observe that in the (unique) maximizing position, $\beta = \gamma = \frac{\pi - \alpha}{2}$.

**Case 3:** The path $A_1A_2A_3$ is of type ++ (or symmetrically, −−). If $A_2$ lies below $\Delta$, $|A_1A_2|$ can be (possibly) increased by moving $A_1$ to the intersection between $\partial \Omega$ and the horizontal line through $A_2$. The new path $A_1A_2A_3$ is $x$-monotone, still lies above $BC$, but is now of type ++ (Case 1, above). If $A_2$ lies above $\Delta$, $|A_2A_3|$ can be (possibly) increased by moving $A_3$ to the intersection between $\partial \Omega$ and the horizontal line through $A_2$. The new path $A_1A_2A_3$ is $x$-monotone, still lies above $BC$, but is now of type −− (Case 2, above). In either case, since one edge of $A_1A_2A_3$ is horizontal, the length of $A_1A_2A_3$ can be further strictly increased by using the operations described in Case 2.

This concludes our case analysis. If any increase had occurred, a simple polygon whose perimeter is strictly larger than that of $P$ could be constructed by taking the new path $A_1A_2A_3$ and then going back and forth near $A_2A_3$ with the remaining $n-2$ edges. However, this would contradict the fact that $P$ was an extremal polygon. Observe that $L_1 \leq 4\cos \alpha$ can hold with equality only in Case 2. We have thus shown that for a fixed length $z$, $L_1$ is maximized when $z$ is a chord of $\Omega$, $A_1 = B$, $A_3 = C$, and $|A_2A_1| = |A_2A_3|$ with $A_1, A_2, A_3$ on the circle.

Since $z = 2\sin \alpha$ is the length of a longest side, by Lemma 3 we get

\[ F(n) \leq L_1 + (n-2)z \leq 4\cos \alpha + 2(n-2)\sin \alpha. \] (19)

We are thus led to maximizing the following function of one variable $\alpha \in [0, \pi/2]$

\[ f(\alpha) = 4\cos \alpha + 2(n-2)\sin \alpha. \]

The function $f(\cdot)$ is maximized at the root of the derivative:

\[ f'(\alpha) = -2\sin \alpha + 2(n-2)\cos \alpha. \]

Making the substitution $x = \sin \alpha/2$, and using the trigonometric identity $\cos \alpha = 1 - 2\sin^2 \alpha/2$, yields the quadratic equation in $x$:

\[ -2x + 2(n-2)(1-2x^2) = 0, \text{ or } 2(n-2)x^2 + x - (n-2) = 0. \]

The solution (corresponding to $\alpha \in [0, \pi/2]$) is

\[ x = \sin \alpha/2 = \frac{-1 + \sqrt{1+8(n-2)^2}}{4(n-2)}. \] (20)

This implies

\[ \cos \alpha/2 = \sqrt{1-\sin^2 \alpha/2} = \frac{\sqrt{8(n-2)^2 - 2 + 2\sqrt{1+8(n-2)^2}}}{4(n-2)}. \]

Consequently, $F(n)$ is bounded from above by the maximum value of $f(\cdot)$, namely

\[ F(n) \leq 4\cos \alpha + 2(n-2)\sin \alpha = 4\cos \alpha/2 \left((n-2)\sin \alpha/2 + 1\right) \]

\[ = \frac{\sqrt{8(n-2)^2 - 2 + 2\sqrt{1+8(n-2)^2}} \cdot (\sqrt{1+8(n-2)^2} + 3)}{4(n-2)} = H(n). \] (21)
To see that this upper bound is tight construct a simple polygon as follows. Let $A_1A_3$ be a horizontal chord of length $z = 2 \sin \alpha$, below the center $o$, with $\alpha$ set according to (20). Let $A_2$ be the intersection point above $A_1A_3$ of the vertical bisector of $A_1A_3$ with the unit circle $\partial \Omega$. The remaining $n - 2$ sides of the polygon go back and forth near the horizontal chord $A_1A_3$. Thus formula (10) holds for every odd $n \geq 3$. This concludes the proof of Theorem 6. \hfill \Box

**Proof of Theorem 6.** We start with the upper bound on $G(n)$. Consider the set of $n$-gons contained in $\Omega$, where each such $n$-gon is given by the $n$-tuple of its vertex coordinates. Note that this forms a compact set, hence there exists an extremal polygon $P = A_1 \ldots A_n$, where $(A_{n+1} = A_1)$ which attains the maximum perimeter. Observe two properties of $P$ that we justify below:

- Each vertex of $P$ lies on $\partial \Omega$.
- All sides of $P$ have equal length $\leq 2$.

First, assuming that $A_i$ lies in the interior of $\Omega$, per($P$) could be increased by moving $A_i$ orthogonally away from $A_{i-1}A_{i+1}$, or away from $A_{i-1}$ in case $A_{i-1} = A_{i+1}$. This would contradict the maximality of $P$, hence all vertices of $P$ lie on the circle. Second, assume now that $A_{i-1}, A_i, A_{i+1}$ lie on the circle $\partial \Omega$, and $|A_{i-1}A_i| \neq |A_iA_{i+1}|$. Then per($P$) could be increased by moving $A_i$ on the circle and further from $A_{i-1}A_{i+1}$ (to the midpoint of the arc). This again would contradict the maximality of $P$, hence all vertices of $P$ are equal. Since $n$ is odd, it is obvious that the common edge length is strictly smaller than 2, since otherwise $A_{n+1}$ cannot coincide with $A_1$.

Having established the two properties above, we can now easily obtain an upper bound on the perimeter of $P$. Let $o$ be the center of $\Omega$. For each $i \in [n]$, label the side $A_iA_{i+1}$ by + or − depending on whether the center $o$ lies on the right of $A_iA_{i+1}$ or on the left of $A_iA_{i+1}$. This labeling encodes the winding of the edges of $P$ around the center $o$. Let $[n] = \Gamma_+ \cup \Gamma_-$ be the corresponding partition of $[n]$ determined by a positive or, respectively, negative labeling of $A_iA_{i+1}$. Write $k = |\Gamma_+|$, and $l = |\Gamma_-|$, so $k + l = n$.

We can assume that $l = 0$; indeed if both $k > 0$ and $l > 0$, then there exist two consecutive sides, $A_{i-1}A_i$ and $A_iA_{i+1}$, one with a positive label and one with a negative label. This implies that $A_{i-1} = A_{i+1}$, hence per($P$) could be increased (recall that the side length is smaller than 2) by moving $A_i$ to the point diametrically opposite to $A_{i-1}$ (and $A_{i+1}$), a contradiction. Hence $l = 0$, $\Gamma_- = \emptyset$, and $\Gamma = \Gamma_+ = [n]$. For each $i \in [n]$, let $\angle A_i o A_{i+1} = 2\alpha$, where $0 < \alpha < \frac{\pi}{2}$. Since $P$ is a closed polygonal chain, $2n\alpha = m\pi$ for some positive integer $m$, $1 \leq m \leq n - 1$. Consequently, the perimeter of $P$ is

$$\text{per}(A_1 \ldots A_n) = 2n \sin \alpha = 2n \sin \frac{m\pi}{2n} \leq 2n \sin \frac{(n - 1)\pi}{2n} = 2n \cos \frac{\pi}{2n},$$

(22)

as claimed.

It remains to show that this bound can be attained. Consider $n$ points evenly distributed on the unit circle, and labeled from 1 to $n$, say in clockwise order. The polygon we need is the thrackle which connects the point labeled $i$ with the point labeled $i + \frac{n-1}{n}$ (as usually the indexes are taken modulo $n$). It is easy to verify that its perimeter is given by the upper bound in (22), and this concludes the proof of Theorem 6. \hfill \Box

**Remarks.** For instance, $F(3) = 3\sqrt{3} = 5.19 \ldots$ corresponds to an equilateral triangle of side $\sqrt{3}$, and $F(5) = \sqrt{70 + 2\sqrt{73} \cdot (\sqrt{73} + 3)/12} = 8.9774 \ldots$. The exact formula (10) easily yields an
approximation of the form:

\[ F(n) = 2(n - 2) + 2\sqrt{2} + O \left( \frac{1}{n} \right). \]

Note that the sum of the first two terms in this formula, \(2(n - 2) + 2\sqrt{2}\), gives (in the limit) the perimeter of a simple polygon whose first two sides have length \(\sqrt{2}\) each, and whose remaining \(n - 2\) sides go back and forth near a diameter of the unit disk. Thus the perimeter of the extremal polygon in Theorem 5 exceeds the perimeter of the polygon described above only by a term that tends to zero with \(n\).

It is interesting to observe that (for odd \(n\)) in contrast to \(F(n)\), \(G(n)\) does get arbitrarily close to \(2n\), as \(n\) tends to infinity; that is, \(G(n) = 2n - o(1)\). Indeed, the series expansion of \(\cos x\) around \(x = 0\), \(\cos x = 1 - \frac{x^2}{2} + \ldots\) gives

\[ G(n) = 2n \cos \frac{\pi}{2n} = 2n \left( 1 - \frac{\pi^2}{8n^2} + \ldots \right) = 2n - \frac{\pi^2}{4n} + \ldots = 2n - o(1). \]

Acknowledgment. The author is grateful to an anonymous reviewer for pointing out a gap in our earlier proof of Theorem 5 and for suggesting a significantly shorter proof of Theorem 6.
