CLASSIFICATION OF FINITE ALEXANDER QUANDLES

SAM NELSON

Abstract. Two finite Alexander quandles with the same number of elements are isomorphic iff their $\mathbb{Z}[t^\pm 1]$-submodules $\text{Im}(1-t)$ are isomorphic as modules. This yields specific conditions on when Alexander quandles of the form $\mathbb{Z}_n[t^\pm 1]/(t - a)$ where $\gcd(n, a) = 1$ (called linear quandles) are isomorphic, as well as specific conditions on when two linear quandles are dual and which linear quandles are connected. We apply this result, obtaining a procedure for classifying Alexander quandles of any finite order and as an application we list the numbers of distinct and connected Alexander quandles with up to fifteen elements.

1. Introduction

In [4], D. Joyce defined the fundamental quandle, an algebraic invariant of knots which classifies classical knots. The set of quandles forms a category whose axioms are algebraic versions of the three Reidemeister moves. Quandles are useful both for defining new knot invariants (as in [1]) and for improving our understanding of old ones (see [2], for example).

The ability to distinguish quandles would allow us to distinguish knots. While there is not yet a complete classification theorem for general quandles, there are classification results for quandles of prime order [6] and for indecomposable quandles of prime squared order [3]. In this paper we classify finite Alexander quandles by

2000 Mathematics Subject Classification. 57M27.
Key words and phrases. Alexander Quandles, Knot Invariants.
reducing the problem of comparing finite Alexander quandles to comparing certain $\mathbb{Z}[t^{\pm 1}]$-submodules.

**Definition 1.1.** A **quandle** is a set $X$ with a binary operation written as exponentiation satisfying

(i) For every $a, b \in X$ there exists a unique $c \in X$ such that $a = c^b$,

(ii) For every $a, b, c \in X$ we have $a^{bc} = a^{cb}$, and

(iii) For every $a \in X$ we have $a^a = a$.

Any module over $\Lambda = \mathbb{Z}[t^{\pm 1}]$ is a quandle under the operation $a^b = ta + (1 - t)b$. Quandles of this form are called **Alexander quandles**. To obtain finite Alexander quandles, we typically consider $\Lambda_n/(t - a)$ where $\Lambda_n = \mathbb{Z}_n[t^{\pm 1}]$ and $h$ is a monic polynomial in $t$. In an earlier version of [6], the questions of when two Alexander quandles of the form $\Lambda_n/(t - a)$ with $\gcd(n,a) = 1$ (we call Alexander quandles of this form **linear**) are isomorphic and of when two linear quandles are dual were posed.

To answer these questions, we first consider the general case of when two arbitrary Alexander quandles of finite cardinality are isomorphic. We obtain a result which reduces the problem of comparing Alexander quandles to comparing certain $\Lambda$-submodules. We then apply this result, obtaining a pair of simple conditions on $a$ and $b$ which are necessary and sufficient for two linear Alexander quandles $\Lambda_n/(t - a)$ and $\Lambda_n/(t - b)$ to be isomorphic.

In the course of answering the question of classifying linear quandles, we also answer the question of when linear quandles are dual and we obtain results on when Alexander quandles are connected.

## 2. Alexander Quandles and $\Lambda$-modules

Since the quandle structure of an Alexander quandle is determined by its $\Lambda$-module structure, any isomorphism of $\Lambda$-modules is also an isomorphism of Alexander quandles. The converse is not true, however: $\Lambda_9/(t - 4)$ is isomorphic to $\Lambda_9/(t - 7)$ as an Alexander quandle but not as a $\Lambda$-module.

Nonetheless, an isomorphism of Alexander quandles is in a sense almost an isomorphism of $\Lambda$-modules; in fact, (after applying a shift if necessary) the restriction of a quandle isomorphism $f : M \to N$ to the submodule $(1 - t)M$ is a $\Lambda$-module isomorphism onto the
image of the restriction. Theorem 2.1 says that the converse is true as well; that is, we can determine whether two Alexander quandles of the same finite cardinality are isomorphic simply by comparing these $\Lambda$-submodules. This reduces the problem of classifying finite Alexander quandles to comparing $\Lambda$-modules of the form $(1-t)M$.

**Theorem 2.1.** Two finite Alexander quandles $M$ and $N$ of the same cardinality are isomorphic as quandles iff there is an isomorphism of $\Lambda$-modules $h : (1-t)M \to (1-t)N$.

**Proof.** Let $M$ and $N$ be finite Alexander quandles and $f : M \to N$ a quandle isomorphism. We may assume without loss of generality that $f(0) = 0$ since $f' : M \to N$ defined by $f'(x) = f(x) + c$ is also an isomorphism of Alexander quandles for any $c \in N$. Then $f(tx + (1-t)y) = tf(x) + (1-t)f(y)$ implies

$$f(tx) = f(tx + (1-t)0) = tf(x) + (1-t)f(0) = tf(x)$$

and

$$f((1-t)y) = f(t0 + (1-t)y) = tf(0) + (1-t)f(y) = (1-t)f(y)$$

so that

$$(2.1) \hspace{1cm} f(tx + (1-t)y) = f(tx) + f((1-t)y).$$

Denote $M' = (1-t)M$ and $N' = (1-t)N$. Since $t^{-1} \in \Lambda$, every element of $M$ is $tx$ for some $x \in M$, and since $f(0) = 0$, $f$ takes the coset $0 + M'$ of $M'$ in $M = M/M'$ to the coset $0 + N'$ of $N'$ in $N = N/N'$, so we have that $h = f|_{M'} : M' \to N'$ is a homomorphism of $\Lambda$-modules. Since $f$ is injective, its restriction $h$ is a bijection onto its image $0 + N' = N'$, and hence $h$ is an isomorphism of $\Lambda$-modules.

Conversely, suppose $h : M' \to N'$ is an isomorphism of finite $\Lambda$-modules with $|M| = |N|$. Let $A \subset M$ be a set of representatives of cosets of $M'$ in $M$. Then every $m \in M$ has the form $m = \alpha + \omega$ for a unique $\alpha \in A$ and $\omega \in M'$. We will show that there exists a bijection $k : A \to B$ onto a set $B$ of representatives of cosets of $N'$ in $N$ such that the map $f : M \to N$ defined by

$$f(\alpha + \omega) = k(\alpha) + h(\omega)$$

is an isomorphism of Alexander quandles (though typically not of $\Lambda$-modules).
Let $\alpha_1, \alpha_2 \in A$ and $\omega_1, \omega_2 \in (1-t)M$. For any $\alpha_1 \in A$ we have $t\alpha_1 = \alpha_1 - (1-t)\alpha_1$, so that
\[
\begin{align*}
f(t(\alpha_1 + \omega_1) + (1-t)(\alpha_2 + \omega_2)) &= f(\alpha_1 + t\omega_1 + (1-t)(\alpha_2 - \alpha_1 + \omega_2)) \\
&= k(\alpha_1) + h(t\omega_1 + (1-t)(\alpha_2 - \alpha_1 + \omega_2)) \\
&= k(\alpha_1) + th(\omega_1) + h((1-t)\alpha_2) \\
&= -h((1-t)\alpha_1) + (1-t)h(\omega_2).\end{align*}
\]
On the other hand,
\[
\begin{align*}
tf(\alpha_1 + \omega_1) + (1-t)f(\alpha_2 + \omega_2) &= t(k(\alpha_1) + h(\omega_1)) + (1-t)(k(\alpha_2) + h(\omega_2)) \\
&= tk(\alpha_1) + th(\omega_1) + (1-t)k(\alpha_2) + (1-t)h(\omega_2)
\end{align*}
\]
so for $f$ to be a homomorphism of quandles it is sufficient that
\[
(2.2) \quad (1-t)k(\alpha_1) - h((1-t)\alpha_1) = (1-t)k(\alpha_2) - h((1-t)\alpha_2)
\]
for all $\alpha_1, \alpha_2 \in A$. We will show that given a set of coset representatives $A \subset M$ we can choose a set $B \subset N$ of coset representatives and a bijection $k : A \rightarrow B$ so that $(1-t)k(\alpha) = h((1-t)\alpha)$ for all $\alpha \in A$, which satisfies $(2.2)$ and thus yields a homomorphism $f : M \rightarrow N$ of Alexander quandles. Since this $f$ is setwise the Cartesian product $k \times h$ of the bijections $k : A \rightarrow B$ and $h : M' \rightarrow N'$, $f$ is bijective and hence an isomorphism of quandles.

Denote $M'' = (1-t)^2M$, $M = M'/M''$ and similarly for $N$. The isomorphism $h : M' \rightarrow N'$ induces an isomorphism $\tilde{h} : \tilde{M} \rightarrow \tilde{N}$. There are surjective maps $\psi : \tilde{M} \rightarrow \tilde{M}$ and $\phi : \tilde{N} \rightarrow \tilde{N}$ induced by multiplication by $(1-t)$. Then $|M'| = |N'|$ and $|M| = |N|$ imply that $|\tilde{M}| = |\tilde{N}|$, and in turn $|\tilde{M}| = |\tilde{N}|$.

Then $|\psi^{-1}(y)| = |\psi^{-1}(y')|$ for all $y, y' \in \tilde{M}$, since $\psi(y) = \psi(0) + \psi(y)$ implies that for each element of $\psi^{-1}(0)$ there is an element of $\psi^{-1}(y)$, that is, $|\psi^{-1}(y)| \geq |\psi^{-1}(0)|$, and similarly $\psi(0) = \psi(y) + \psi(-y)$ implies that $|\psi^{-1}(0)| \geq |\psi^{-1}(y)|$. Hence $|\psi^{-1}(y)| = |M|/|\tilde{M}|$ for all $y \in \tilde{M}$, and similarly $|\phi^{-1}(h(y))| = |\tilde{N}|/|\tilde{N}| = |\tilde{M}|/|\tilde{N}|$ for all $y \in \tilde{M}$. Thus there is a bijection of sets $g : \tilde{M} \rightarrow \tilde{N}$.
such that the diagram

\[
\begin{array}{ccc}
\bar{M} & \xrightarrow{g} & \bar{N} \\
\psi \downarrow & & \downarrow \phi \\
\bar{M} & \xrightarrow{\bar{h}} & \bar{N}
\end{array}
\]

commutes.

Let \( B \) be a set of coset representatives for \( \bar{N} \). Then there is a unique bijection \( k : A \to B \) such that

\[
\begin{array}{ccc}
A & \xrightarrow{k} & B \\
\downarrow & & \downarrow \\
\bar{M} & \xrightarrow{\bar{h}} & \bar{N}
\end{array}
\]

commutes. In particular, \( \bar{h}\psi(\alpha) = \phi k(\alpha) \), that is,

\[
(2.3) \quad \bar{h}((1-t)\alpha + (1-t)^2M) = (1-t)k(\alpha) + (1-t)^2N.
\]

Define \( \gamma : M' \to \bar{M} \) and \( \epsilon : N' \to \bar{N} \) by \( \gamma((1-t)m) = (1-t)m + (1-t)^2M \in \bar{M} \) and \( \epsilon((1-t)n) = (1-t)n + (1-t)^2N \in \bar{N} \), the classes of \((1-t)m\) and \((1-t)n\) in \( \bar{M} \) and \( \bar{N} \) respectively. We then have commutative diagrams

\[
\begin{array}{ccc}
A & \xrightarrow{(1-t)} & M' \\
\downarrow & & \downarrow \gamma \\
\bar{M} & \xrightarrow{\psi} & \bar{M}
\end{array} \quad \text{and} \quad 
\begin{array}{ccc}
B & \xrightarrow{(1-t)} & N' \\
\downarrow & & \downarrow \epsilon \\
\bar{N} & \xrightarrow{\phi} & \bar{N}
\end{array}
\]

Equation (2.3) then says that outside rectangle of the diagram

\[
\begin{array}{ccc}
(1-t)A & \xrightarrow{k} & (1-t)B \\
\downarrow & & \downarrow \\
M' & \xrightarrow{\bar{h}} & N'
\end{array}
\]

commutes. The bottom square commutes by definition of \( \bar{h} \), and thus we have \( \epsilon(\bar{h}((1-t)\alpha)) = \epsilon((1-t)k(\alpha)) \), that is,

\[
h((1-t)\alpha) + (1-t)^2N = (1-t)k(\alpha) + (1-t)^2N.
\]
In particular, there is a $\xi \in N$ so that
\[ h((1 - t)\alpha) = (1 - t) k(\alpha) + (1 - t)^2 \xi = (1 - t)(k(\alpha) + (1 - t)\xi). \]
Then for each $\alpha \in A$ with $\xi \neq 0$ we may replace $k(\alpha)$ with the
coset representative $k'(\alpha) = k(\alpha) + (1 - t)\xi$ to obtain a new set
$B'$ of coset representatives for $N$ and a bijection $k' : A \to B'$ with
$(1 - t)k'(\alpha) = h((1 - t)\alpha)$ so that (2.2) is satisfied. Then $f : M \to N$
by $f(\alpha + \omega) = k'(\alpha) + h(\omega)$ for all $\alpha \in A$ is an isomorphism of
Alexander quandles, as required. \qed

As a consequence, we obtain Corollary 2.2 which gives specific
conditions on $a$ and $b$ for $\Lambda_n/(t - a)$ and $\Lambda_n/(t - b)$ to be isomorphic
Alexander quandles when $a$ and $b$ are coprime to $n$.

Denote $N(n, a) = \frac{n}{\gcd(n, 1 - a)}$ for any $a \in \mathbb{Z}_n$. We will use the
symbol $\cong$ to denote an isomorphism of quandles and $\approx$ to denote
an isomorphism of $\Lambda$-modules.

**Corollary 2.2.** Let $a$ and $b$ be coprime to $n$. Then the Alexander
quandles $\Lambda_n/(t - a)$ and $\Lambda_n/(t - b)$ are isomorphic iff $N(n, a) = N(n, b)$ and $a \equiv b(\text{mod } N(n, b))$.

**Proof.** By theorem 2.1

\[ \Lambda_n/(t - a) \cong \Lambda_n/(t - b) \iff (1 - t)[\Lambda_n/(t - a)] \cong (1 - t)[\Lambda_n/(t - b)]. \]

As a $\mathbb{Z}$-module, $(1 - t)[\Lambda_n/(t - a)]$ is $(1 - a)\mathbb{Z}_n$ and $(1 - t)[\Lambda_n/(t - b)]$
is $(1 - b)\mathbb{Z}_n$ with the action of $t$ given by multiplication by $a$ in
$(1 - a)\mathbb{Z}_n$ and by $b$ in $(1 - b)\mathbb{Z}_n$.

The $\mathbb{Z}$-module $(1 - a)\mathbb{Z}_n$ is isomorphic to $\mathbb{Z}_n/\text{Ann}(1 - a)$, so

\[ \Lambda_n/(t - a) \cong \Lambda_n/(t - b) \iff \mathbb{Z}_n/\text{Ann}(1 - a) \cong \mathbb{Z}_n/\text{Ann}(1 - b) \]
\[ \iff \text{Ann}(1 - a) = \text{Ann}(1 - b) \]
\[ \iff \text{Ord}_{\mathbb{Z}_n}(1 - a) = \text{Ord}_{\mathbb{Z}_n}(1 - b) \]
\[ \iff \frac{n}{\gcd(n, 1 - a)} = \frac{n}{\gcd(n, 1 - b)} \]
\[ \iff N(n, a) = N(n, b). \]

Denote $n' = N(n, a) = N(n, b)$. Then $(1 - t)[\Lambda_n/(t - a)]$ is $\mathbb{Z}_{n'}$ with $t$
acting by multiplication by $a$, and if $N(n, a) = N(n, b) = n'$ then
$(1 - t)[\Lambda_n/(t - b)]$ is $\mathbb{Z}_{n'}$ with $t$ acting by multiplication by $b$.

Multiplication by $a$ agrees with multiplication by $b$ on $\mathbb{Z}_{n'}$ iff $a \equiv b(\text{mod } n')$, so the $\Lambda$-module structures on $\mathbb{Z}_{n'}$ determined by $a$
and $b$ agree iff $a \equiv b(\text{mod } n')$. \qed
Definition 2.3. A quandle \( M \) is connected if it has only one orbit, i.e. if the set \( \{a^b : b \in M\} = M \) for all \( a \in M \). In particular, an Alexander quandle is connected if \((1-t)M = M\).

Corollary 2.4. Two finite connected Alexander quandles are isomorphic iff they are isomorphic as \( \Lambda \)-modules.

Proof. This follows from the proof of theorem 2.1. Specifically, if \( M \) and \( N \) are connected and \( f : M \to N \) is an isomorphism of quandles with \( f(0) = 0 \), then \( f \) is an isomorphism of \( \Lambda \)-modules.

Corollary 2.5. A linear Alexander quandle \( \Lambda_n/(t-a) \) is connected iff \( \gcd(n, 1-a) = 1 \).

Proof. An Alexander quandle is connected iff \( M = (1-t)M \). Since \((1-t)[\Lambda_n/(t-a)] \) is \( \mathbb{Z}_{n_a} \) with \( t \) acting by multiplication by \( a \), we have \( \Lambda_n/(t-a) \) is connected iff \( n_a = n \), that is, iff \( \gcd(n, 1-a) = 1 \).

Corollary 2.6. No linear Alexander quandle \( \Lambda_n/(t-a) \) with \( n \) even is connected.

Proof. To have a linear quandle \( \Lambda_n/(t-a) \) with \( n \) elements, we must have \( \gcd(n, a) = 1 \), so if \( n \) is even, \( a \) must be odd. But then \( 1-a \) is even and \( \gcd(n, 1-a) \neq 1 \), and \( \Lambda_n/(t-a) \) is not connected.

For each \( y \in X \) we can define a map of sets \( f_y : X \to X \) by \( f_y(x) = x^y \). Quandle axiom (i) then says that \( f_y \) is a bijection for each \( y \in X \). We may then define a new quandle structure on \( X \) by \( x^y = f_y^{-1}(x) \); this is the dual quandle of \( X \).

Lemma 2.7. The dual of an Alexander quandle \( X \) is the set \( X \) with quandle operation given by \( x^y = t^{-1}x + (1-t^{-1})y \).

Proof. If \( f_y(x) = c = tx + (1-t)y \) then \( t^{-1}c = x + (t^{-1} - 1)y \Rightarrow x = t^{-1}c + (1-t^{-1})y \); thus \( f_y^{-1}(x) = t^{-1}x + (1-t^{-1})y \).

Corollary 2.8. Let \( a, b \) be coprime to \( n \). Then \( \Lambda_n/(t-a) \) is dual to \( \Lambda_n/(t-b) \) iff \( n_a = n_b \) and \( ab \equiv 1 \pmod{n_a} \). In particular, a linear Alexander quandle \( \Lambda_n/(t-a) \) is self-dual iff \( a \) is a square mod \( n_a \).

Proof. If \( n \) and \( a \) are coprime, then \( a \) is invertible in \( \mathbb{Z}_n \) and the dual of \( \Lambda_n/(t-a) \) is given by \( \Lambda_n/(t-a^{-1}) \) by lemma 2.7. Then
Corollary 2.2 says that $\Lambda_n / (t - b)$ is isomorphic to $\Lambda_n / (t - a^{-1})$ iff $n_b = n_{a^{-1}}$ and $b \equiv a^{-1} \pmod{n_b}$.

Since $\gcd(n, a) = 1$ we have $\gcd(n, 1 - a) = \gcd(n, -a(1 - a^{-1})) = \gcd(n, 1 - a^{-1})$ so that $n_a = n_{a^{-1}}$ as required. \hfill \qed

3. $\mathbb{Z}$-automorphisms and Computations

Let $X$ be a finite Alexander quandle and let $X_A$ denote $X$ regarded as an Abelian group, called the underlying Abelian group of $X$. The map $\phi : X_A \to X_A$ defined by $\phi(x) = tx$ is a homomorphism of $\mathbb{Z}$-modules. Since $t^{-1} \in \Lambda$, the map $\psi : X_A \to X_A$ defined by $\psi(x) = t^{-1}x$ is a two-sided inverse for $\phi$ as $\psi(\phi(x)) = t^{-1}tx = x$ and $\phi(\psi(x)) = tt^{-1}x = x$, and $\phi$ is in fact a $\mathbb{Z}$-automorphism.

Conversely, if $A$ is a finite Abelian group and $\phi : A \to A$ is a $\mathbb{Z}$-module automorphism, we can give $A$ the structure of an Alexander quandle by defining $tx = \phi(x)$. This yields a general strategy for listing all finite Alexander quandles of a given size $n$: first, list all Abelian groups $A$ of order $n$; then, for each element of $\text{Aut}_\mathbb{Z}(A)$ find $(1 - t)A = \text{Im}(1 - \phi)$ and compare these as $\Lambda$-modules. In practice, for low order (i.e., $|A| \leq 15$) Alexander quandles this procedure in its full generality is necessary only for one case, namely Alexander quandles with underlying Abelian group isomorphic to $\mathbb{Z}_4 \oplus \mathbb{Z}_2$. We shall see that Alexander quandles with underlying Abelian group isomorphic to $\mathbb{Z}_4 \oplus \mathbb{Z}_2$ are isomorphic to linear Alexander quandles (in six cases) or to Alexander quandles with underlying group $(\mathbb{Z}_2)^3$ (in two cases).

We first obtain a few simplifying results:

**Lemma 3.1.** If the underlying Abelian group $X_A$ of $X$ is cyclic, then $X$ is linear.

*Proof.* Suppose $X_A = \mathbb{Z}_n$. Then for any $x \in \mathbb{Z}_n$ and any $\phi \in \text{Aut}_\mathbb{Z}(\mathbb{Z}_n)$, we must have $\phi(x) = \phi(x \cdot 1) = x\phi(1)$, so the action of $t$ agrees with multiplication by $a = \phi(1)$ on $\mathbb{Z}_n$. Further, we must have $\gcd(n, a) = 1$ since $\phi$ is surjective. Hence $X$ is $\mathbb{Z}_n$ with $t$ acting by multiplication by $a$, that is, $X \cong \Lambda_n / (t - a)$.

*Remark 3.2.* Lemma 3.1 was also noted in [6].

**Corollary 3.3.** For any prime $p$, there are exactly $p - 1$ distinct Alexander quandles with $p$ elements, namely $\Lambda_p / (t - a)$ for $a = 1, \ldots, p - 1$. Further, every Alexander quandle of prime order is
either trivial ($\Lambda_p/(t-1) \cong T_p$, the trivial quandle of $p$ elements) or connected.

**Proof.** If $p$ is prime, $n_a = \frac{n}{\gcd(p,1-a)} = 1$ for each $a \in 1, \ldots, p-1$. Then by corollary 2.2 these are all distinct. By lemma 3.1 every quandle of order $p$ is linear, so these are all of the Alexander quandles of order $p$.

Since $\gcd(p,1-a) = 1$ for $a = 2, \ldots, p-1$, corollary 2.5 gives us that $\Lambda_p/(t-a)$ is connected. \hfill \Box

**Corollary 3.4.** Let $n = p_1^{e_1}p_2^{e_2}\cdots p_k^{e_k}$ be a product of powers of distinct primes. Then there are exactly $N_{p_1}N_{p_2}\cdots N_{p_k}$ distinct Alexander quandles of order $n$, where $N_{p_i}$ is the number of distinct Alexander quandles of order $p_i^{e_i}$.

**Proof.** Since any $\mathbb{Z}$-automorphism must respect order, any Alexander quandle structure on a direct sum of Abelian groups $A_{p_1^{e_1}} \oplus \cdots \oplus A_{p_k^{e_k}}$ with order $p_1^{e_1}, \ldots, p_k^{e_k}$ must respect this direct sum structure. Hence we may obtain a complete list of Alexander quandles of order $n$ by listing all direct sums of Alexander quandles of orders $p_1^{e_1}, \ldots, p_k^{e_k}$.

\hfill \Box

**Corollary 3.5.** If the order of an Alexander quandle $n \equiv 2(\text{mod } 4)$, the quandle is not connected.

**Proof.** If $n \equiv 2(\text{mod } 4)$, then the underlying Abelian group of the quandle has a summand of $\mathbb{Z}_2$. Hence the quandle has a summand isomorphic to $\Lambda_2/(t+1) \cong T_2$, and therefore is not connected. \hfill \Box

In light of corollary 3.4 to classify finite Alexander quandles it is sufficient to consider Alexander quandles of prime power order. Alexander quandles with prime order are cyclic as Abelian groups and hence are linear quandles, and so are classified by corollary 3.3. Alexander quandles with order a product of distinct primes are classified by corollary 3.4.

If the underlying Abelian group of $X$ is $(\mathbb{Z}_p)^n$, then $X$ is not only a $\Lambda$-module but also a $\Lambda_p$-module, so we may use the classification theorem for finitely generated modules over a PID. Thus any Alexander quandle $X$ with $X_A = (\mathbb{Z}_p)^n$ must be of the form $\Lambda_p/(h_1) \oplus \cdots \oplus \Lambda_p/(h_k)$ with $h_1|h_2|\cdots|h_k$, $h_i \in \Lambda_p$ and $\sum \deg(h_i) = n$. We may further assume without loss of generality that each $h_i \in \mathbb{Z}_p[t]$, is monic, and has nonzero constant term.
Hence every $m$ that every $l$− and hence $\ker(1 - t)$ is bijective. If $(1 - t) M = M$ iff $(1 - t) : M \to M$ is bijective. If $(1 - t) h$ then $h = (1 - t) g$ for some nonzero $g \in M$, and hence $\ker(1 - t) \neq \{0\}$, so $(1 - t)$ fails to be injective.

Conversely, $(1 - t)$ is prime in $\Lambda$, so $(1 - t)$ coprime to $h$ implies that every $l \in \Lambda$ may be written as $a(1 - t) + bh$ for some $a, b \in \Lambda$. Hence every $m \in M$ is $a(1 - t)$ for some $a \in M$.

Proposition 3.7. The Alexander quandle $\Lambda_p^\times / \left( t^n + \sum_{i=0}^{n-1} a_i t^i \right)$ is connected iff $\sum_{i=0}^{n-1} a_i = -1$.

Proof. By 3.6, $\Lambda_p^\times / \left( t^n + \sum_{i=0}^{n-1} a_i t^i \right)$ is connected iff $(t - 1) \left( t^{n-1} + \sum_{i=0}^{n-2} b_i t^i \right) = t^n + \sum_{i=0}^{n-1} a_i t^i$.

Comparing coefficients, we must have that $a_{n-1} + b_{n-2} = -1$, $b_i = a_i + b_{i-1}$ for all $1 \leq i \leq n - 2$, and $b_0 = a_0$. Then $\sum_{i=0}^{n-1} a_i = -1$.

Conversely, if $\sum_{i=0}^{n-1} a_i = -1$, define $b_0 = a_0$, $b_i = a_i + b_{i-1}$ for all $1 \leq i \leq n - 2$, and $a_{n-1} + b_{n-2} = -1$.

Proposition 3.8. There are $2p^2 - 3p - 1$ connected Alexander quandles of order $p^2$ where $p$ is prime.\footnote{This agrees with the result of Graña in \cite{Graña}.}

Proof. Every Alexander quandle of order $p^2$ has underlying Abelian group $\mathbb{Z}_{p^2}$ or $\mathbb{Z}_p \oplus \mathbb{Z}_p$. A linear quandle $\Lambda_p^\times / (t - a)$ of order $p^2$ is connected iff gcd$(1 - a, p) = 1$, and there are $p(p - 2)$ such quandles.

An Alexander quandle $M$ with underlying Abelian group $\mathbb{Z}_p \oplus \mathbb{Z}_p$ is a module over the PID $\Lambda_p$, so we have either $M \cong \Lambda_p / (t - a) \oplus \Lambda_p / (t - a)$ or $M \cong \Lambda_p / (t^2 + at + b)$ where $b \neq 0$. There are $p - 2$ connected quandles of the first type and $(p - 1)^2$ of the second type, so in total there are $2p^2 - 3p - 1$ connected Alexander quandles of order $p^2$.\qed
CLASSIFICATION OF FINITE ALEXANDER QUANDLES

For arbitrary values of $n$ and $p$ we may classify Alexander quandles with underlying Abelian group $(\mathbb{Z}_p)^n$ listing all possible $\Lambda$-modules with underlying group $(\mathbb{Z}_p)^n$ and comparing the submodules $\operatorname{Im}(1-t)$.

Results of applying this procedure to Alexander quandles with underlying Abelian group $(\mathbb{Z}_2)^2$, $(\mathbb{Z}_2)^3$ and $(\mathbb{Z}_3)^2$ are collected in Table 1. As we expect, these results agree with proposition 3.8.

Note that by theorem 2.1 and corollary 2.2 the results in table 1 show that $\Lambda_2/(t^2+1) \cong \Lambda_4/(t-3)$ and $(\Lambda_2/(t+1))^2 \cong \Lambda_4/(t-1) \cong T_4$, the trivial quandle of order 4, while $\Lambda_2/(t^2+t+1)$ is the only connected Alexander quandle of order 4.

Alexander quandles with underlying Abelian group $(\mathbb{Z}_2)^3$ include $\Lambda_2/(t+1) \oplus \Lambda_2/(t^2+1) \cong \Lambda_8/(t-5)$ and $(\Lambda_2/(t+1))^3 \cong T_8$. Also, theorem 2.1 yields an isomorphism $\Lambda_8/(t-3) \cong \Lambda_8/(t-7)$; otherwise, the order eight quandles listed are all distinct. Of these,
only $\Lambda_9/(t^3 + t^2 + 1)$ and $\Lambda_2/(t^3 + t + 1)$ are connected. Note that none of the linear Alexander quandles of order eight are connected.

Among Alexander quandles with Abelian group $(\mathbb{Z}_3)^2$, we have $\Lambda_9/(t-4) \cong \Lambda_9/(t-7) \cong \Lambda_9/(t^2 + t + 1)$ (the first isomorphism was noted in [4] and the second also follows from proposition 4.1 of [5]); otherwise, the linear quandles of order nine and the quandles listed in table 1 are all distinct. Note that five of the eight listed quandles of order nine are connected; of the linear quandles of order nine, $\Lambda_9/(t-2)$, $\Lambda_9/(t-5)$ and $\Lambda_9/(t-8)$ are connected.

To count distinct Alexander quandles whose underlying Abelian group is neither cyclic nor a direct sum of $n$ copies of $\mathbb{Z}_p$, the following observation is useful.

**Lemma 3.9.** The number of conjugacy classes in $\text{Aut}_\mathbb{Z}(X_A)$ is an upper bound on the number of distinct Alexander quandles $X$ with underlying Abelian group $X_A$.

**Proof.** Let $\phi_1, \phi_2 \in \text{Aut}_\mathbb{Z}X_A$. Then if $t_1 = \phi_1(1)$ and $t_2 = \phi_2(1)$, we have $\phi_2^{-1}\phi_1\phi_2$ acting by multiplication by $t_2^{-1}t_1t_2 = t_1$ since multiplication in $\Lambda$ is commutative. Thus any two conjugate automorphisms define the same Alexander quandle structure.

To complete the classification of Alexander quandles with up to fifteen elements, we now only need to consider the case $X_A = \mathbb{Z}_4 \oplus \mathbb{Z}_2$.

**Proposition 3.10.** There are three distinct Alexander quandle structures definable on the Abelian group $\mathbb{Z}_4 \oplus \mathbb{Z}_2$, given by $\mathbb{Z}$-automorphisms $\phi_1 = \text{id}$, $\phi_2((1,0)) = (1,1)$, $\phi_2((0,1)) = (0,1)$, $\phi_3((1,0)) = (1,1)$ and $\phi_3((0,1)) = (2,1)$. Further, these quandles are isomorphic to previously listed quandles, namely $(\mathbb{Z}_4 \oplus \mathbb{Z}_2, \phi_1) \cong T_8$, $(\mathbb{Z}_4 \oplus \mathbb{Z}_2, \phi_2) \cong \Lambda_2/(t+1) \oplus \Lambda_2/(t^2+1)$, and $(\mathbb{Z}_4 \oplus \mathbb{Z}_2, \phi_3) \cong \Lambda_2/(t^3 + t^2 + t + 1)$.

**Proof.** Direct calculation shows that $\text{Aut}_\mathbb{Z}(\mathbb{Z}_4 \oplus \mathbb{Z}_2) \cong D_8$, the dihedral group of order eight, so by lemma [39] there are at most five Alexander quandle structures on $\mathbb{Z}_4 \oplus \mathbb{Z}_2$. Of the eight $\mathbb{Z}$-automorphisms of $\mathbb{Z}_4 \oplus \mathbb{Z}_2$, one is the identity, yielding the trivial quandle structure; five have $\text{Im}(1-t) \cong \Lambda_2/(t+1)$ (including $\phi_2$) and hence yield quandles isomorphic to $\Lambda_2/(t+1) \oplus \Lambda_2/(t^2+1)$, and two have $\text{Im}(1-t) \cong \Lambda_2/(t^3 + t^2 + t + 1)$ (including $\phi_3$), yielding quandles isomorphic to $\Lambda_2/(t^3 + t^2 + t + 1)$.

\[\]
We now have enough information to determine all Alexander quandles with up to fifteen elements. In light of corollaries 3.3 and 3.4, we list in table 2 only the numbers of distinct and connected Alexander quandles of each order.

**Table 2.** The number of Alexander quandles and connected Alexander quandles of size $n \leq 15$.

| $n$ | # of Alexander quandles | # connected |
|-----|-------------------------|-------------|
| 2   | 1                       | 0           |
| 3   | 2                       | 1           |
| 4   | 3                       | 1           |
| 5   | 4                       | 3           |
| 6   | 2                       | 0           |
| 7   | 6                       | 5           |
| 8   | 7                       | 2           |
| 9   | 11                      | 8           |
| 10  | 4                       | 0           |
| 11  | 10                      | 9           |
| 12  | 6                       | 1           |
| 13  | 12                      | 11          |
| 14  | 6                       | 0           |
| 15  | 8                       | 3           |
