Abstract
In this paper we generalize an equation studied by Mossino and Temam in [7], to the fully nonlinear case. This equation arises in plasma physics as an approximation to Grad equations, which were introduced by Harold Grad in [4], to model the behavior of plasma confined in a toroidal vessel called TOKAMAK. We prove existence of a $W^{2,p}$-viscosity solution and regularity up to $C^{1,\alpha}$ for any $\alpha < 1$ (we improve this regularity near the boundary). The difficulty of this problem lies in the right-hand side which involves the measure of the superlevel sets, making the problem nonlocal. © 2021 Wiley Periodicals LLC.

Introduction
We will consider $W^{2,p}$-viscosity solutions $u : \Omega \subset \mathbb{R}^n \to \mathbb{R}$ for
\begin{align}
\begin{cases}
F(D^2 u(x)) = g(|u \geq u(x)|) & \text{in } \Omega, \\
u = \psi & \text{on } \partial \Omega,
\end{cases}
\end{align}
where $\Omega \subset \mathbb{R}^n$ is an open, bounded, and connected set, with $C^{1,1}$ boundary. The operator $F : S \to \mathbb{R}$ is a convex, uniformly elliptic operator with ellipticity constants $0 < \lambda \leq \Lambda$, where $S := \{n \times n$ symmetric matrices$\}$. For simplicity we will assume $F(0) = 0$. We will also require that $F$ satisfies the following structure condition:
\begin{align}
\mathcal{M}^-(M - N) \leq F(M) - F(N) \leq \mathcal{M}^+(M - N)
\end{align}
for all $M, N \in S$. Here, $\mathcal{M}^-$ and $\mathcal{M}^+$ are the extremal Pucci operators
\begin{align}
\mathcal{M}^-(M) = \lambda \sum_{e_i > 0} e_i + \Lambda \sum_{e_i < 0} e_i \quad \text{and} \quad \mathcal{M}^+(M) = \Lambda \sum_{e_i > 0} e_i + \lambda \sum_{e_i < 0} e_i,
\end{align}
where $e_i = e_i(M)$ are the eigenvalues of $M$. In the right-hand side of (0.1), $| \cdot |$ denotes the $n$-dimensional Lebesgue measure, and $g : [0; |\Omega|] \to \mathbb{R}$ is a continuous function. We will adopt the notation
\begin{align}
u \geq u(x) := \{y \in \Omega : u(y) \geq u(x)\}
for the superlevel sets of $u$. Finally, we consider a boundary value $\psi \in W^{2,p}(\Omega)$ for $p > n$.

The motivation to study this problem is to generalize Grad equations in plasma physics and its approximations to nonlinear operators. These equations were introduced by Harold Grad in [4] and appear in the literature as queer differential equations (QDEs), or Grad equations. They arise in modeling plasma, which is confined under magnetic forces in a toroidal container (TOKAMAK). Grad noticed that a simplified version of plasma equations was possible using $u^*$, the increasing rearrangement of $u$:

$$u^*(t) := \inf\{s : |u < s| \geq t\}.$$ 

Here is where we start building a connection with our approximation problem (0.1). Notice that heuristically, $u^*$ is the inverse of the measure of the sublevel sets of $u$. In [4], he demonstrated that there are profile functions $\mu$ and $\nu$ which are prescribed by the dynamics of the plasma; consequently, his equation reads

$$\Delta u = -\mu'(u)(u^*)^\gamma - \nu \mu(u)(u^*)^{\gamma-2} u^{*''} - \frac{1}{2}(\nu^2(u))'(u^*)^2 - \nu^2(u) u^{*''}$$

for some power $\gamma$. For clarity we avoided the arguments: $u$ and its derivatives are evaluated at some point $x$ while the rearrangements and its derivatives are evaluated at $t := |u < u(x)|$. Many authors attacked the problem trying to approximate these equations. The first one was introduced by Roger Temam in [8], and then improved by Mossino and Temam in [7]. They studied properties of directional derivatives of the rearrangement function, and proved existence results for

$$\Delta u(x) = g([u < u(x)], u(x)) + f(x).$$

Years later, Laurence and Stredulinsky, in [5][6], studied a model equation, closer to Grad’s formulation. They considered the particular case when $\gamma = 2, \mu = \frac{1}{2}$, and $\nu = 0$ obtaining

$$\Delta u(x) = -u^{*''}([u < u(x)]).$$

Even this simplified case presents many difficulties. The authors introduced a very interesting approach to the problem: they described an approximation with solutions to an $N$-free boundary problem. In order to apply this process they assumed extra regularity for the level sets of a solution, which is mentioned later in Section 3.

The idea behind this paper is the following: all of these previous papers addressed the problem with a variational method for the Laplacian; instead, we will use a viscosity approach for a general family of fully nonlinear operators. A similar equation to the one by Mossino and Temam is studied, and even for the case with the Laplacian we improve the regularity results.

The paper is organized as follows: In the first section we cite some preliminary definitions. Mainly, we state the basics of $W^{2,p}$-viscosity solutions. The classic
theory of viscosity solutions does not apply to this particular problem because of our right-hand side in (0.1). Disregarding the regularity of \( g \) and \( u \), we notice that having \( |u - c| > 0 \) for some constant \( c \) makes the right-hand side of our equation discontinuous. Therefore, we adopt this \( W^{2,p} \)-viscosity notion defined in [2] by Caffarelli, Crandall, Kocan, and Swiech, which allows merely measurable “ingredients”. In their paper they proved existence and interior \( W^{2,p} \)-estimates for solutions to an equation with a fixed right-hand side \( f(x) \). Strongly based on their results, Winter [9] extended this regularity up to the boundary proving global \( W^{2,p} \)-estimates for viscosity solutions and an existence result for \( W^{2,p} \)-strong solutions. For clarity in the presentation, the results from the literature that will be used throughout the paper will be addressed in the Appendix.

In Section 2 we state and prove the main theorem of existence and global regularity. The idea of the proof is to

- freeze \( u \) on the right-hand side,
- solve the resulting equation using [2] theory,
- build a sequence of right-hand sides and solutions,
- use a fixed point argument and a convergence theorem to find a solution.

In Section 3 we prove more regularity under additional hypotheses. As long as \( |
abla u| \) is uniformly bounded below, or equivalently, if we have a uniform interior ball condition for the level sets of \( u \), then we have \( C^{0,\alpha} \) regularity for the right-hand side. This estimate turns into \( C^{2,\alpha} \) regularity for the solution \( u \). We cannot ensure regularity for the level sets, but if we start with a regular enough domain, say \( \partial \Omega \) with a uniform interior ball condition, then we gain \( C^{2,\alpha} \) regularity for \( u \) in a neighborhood of the boundary.

1 Preliminary Definitions

First we are going to present the definitions of viscosity solutions for fully non-linear equations with measurable ingredients, described in the paper of Caffarelli-Crandall-Kocan-Swiech [2]. In this setting we work with the problem

\[
\begin{align*}
F(D^2 u(x)) &= f(x) \quad \text{in } \Omega, \\
\quad u &= \psi \quad \text{on } \partial \Omega,
\end{align*}
\]

where our right-hand side is a fixed measurable function \( f \).

**Definition 1.1.** Let be \( F \) a uniformly elliptic operator, \( f \in L^p(\Omega) \) for \( p > \frac{n}{2} \). Let \( u : \Omega \rightarrow \mathbb{R} \) be a continuous function; we say it is a \( W^{2,p} \)-viscosity subsolution of (1.1) in \( \Omega \) if \( u \leq \psi \) on \( \partial \Omega \) and the following holds: for all \( \varphi \in W^{2,p}(\Omega) \) such that \( u - \varphi \) has a local maximum at \( x_0 \in \Omega \), then

\[
\text{ess lim sup}_{x \to x_0} F(D^2 \varphi(x)) - f(x) \geq 0.
\]

We define supersolutions in the same way: \( u \) is a \( W^{2,p} \)-viscosity supersolution of (1.1) in \( \Omega \) if \( u \geq \psi \) on \( \partial \Omega \) and the following holds: for all \( \varphi \in W^{2,p}(\Omega) \) such that
$u - \varphi$ has a local minimum at $x_0 \in \Omega$, then
\[
\liminf_{x \to x_0} F(D^2\varphi(x)) - f(x) \leq 0.
\]

Remark 1.2. We can also use this alternative definition for $W^{2,p}$-viscosity subsolutions. For all $\varphi \in W^{2,p}_{\text{loc}}(\Omega)$, for all $\varepsilon > 0$, and $O \subset \Omega$ open such that
\[
F(D^2\varphi(x)) - f(x) \leq -\varepsilon,
\]
a.e. in $O$, then $u - \varphi$ cannot have a local maximum in $O$.

Because we will use Winter’s results, we also add the definition of $W^{2,p}$-strong subsolutions.

**Definition 1.3.** In the same setting as before, $u$ is a $W^{2,p}$-strong subsolution of (1.1) in $\Omega$, if $u \leq \psi$ on $\partial \Omega$ and
\[
F(D^2 u(x)) \geq f(x)
\]
a.e. in $\Omega$.

## 2 Main Result

In this section we state and prove existence and a first global regularity result.

**Theorem 2.1.** Our problem (0.1)
\[
\begin{cases}
F(D^2u(x)) = g(|u \geq u(x)|) & \text{in } \Omega, \\
u = \psi & \text{on } \partial \Omega,
\end{cases}
\]
with the setting given in the introduction, has a $W^{2,p}$-viscosity solution $u$. Furthermore, $u \in W^{2,p}(\Omega)$, and we have the following estimate:
\[
\|u\|_{W^{2,p}(\Omega)} \leq C \left[ \|u\|_{L^\infty(\Omega)} + \|\psi\|_{W^{2,p}(\Omega)} + \|g(|u \geq u(x)|)\|_{L^p(\Omega)} \right].
\]

**Corollary 2.2.** Using the Sobolev embedding theorem, we get that a solution is in $C^{1,\alpha}(\Omega)$ for any $\alpha < 1$ provided that $\psi \in W^{2,p}$ for every $p > n$.

The structure of the proof for Theorem 2.1 is somehow simple; we set an approximating problem (2.3), we prove the existence of a solution for it, and then we take the limit to obtain the solution to (0.1). Before presenting this approximating problem in Lemma 2.3, we give a quick explanation on the reasoning behind it. Note that the results from the Appendix will be used next: existence and uniqueness, fixed point, and convergence.

If in (0.1) we freeze a function $v \in \text{Lip}(\Omega)$ for the right-hand side, i.e., $f_v(x) := g(|\{y \in \Omega : v(y) \geq v(x)\}|)$, we get
\[
\begin{cases}
F(D^2u(x)) = f_v(x) & \text{in } \Omega, \\
u = \psi & \text{on } \partial \Omega.
\end{cases}
\]
Then the hypotheses of Theorem A.1 are satisfied, and there exists a unique $W^{2,p}$-viscosity solution $u$ to (2.1). The next step would be to apply the fixed point Theorem A.2 for the application $T(v) = u$. The problem is that we cannot ensure continuity for $T$ because of the right-hand side of (2.1), not even if we require more regularity for $v$ (not even $C^\infty$ works). We will overcome this inconvenience by solving an auxiliary problem with a smoothened right-hand side, which allows us to perform the fixed point argument. Given $v \in \text{Lip}(\Omega), \varepsilon > 0$, consider

$$
F(D^2 u(x)) = f^\varepsilon_v(x) := g \left( \frac{1}{\varepsilon} \int_0^1 |v(x) - h| \, dh \right) \quad \text{in} \ \Omega,
$$

$$
u = \psi \quad \text{on} \ \partial \Omega.
$$

Because $f^\varepsilon_v \in L^p(\Omega)$, using Theorem A.1 we have existence and uniqueness of a $W^{2,p}$-viscosity solution $u \in W^{2,p}(\Omega)$ to (2.2) with the estimate

$$
\|u\|_{W^{2,p}(\Omega)} \leq C \left[ \|v\|_{L^\infty(\Omega)} + \|\psi\|_{W^{2,p}(\Omega)} + \|f^\varepsilon_v\|_{L^p(\Omega)} \right].
$$

Now we can state our approximation lemma.

**Lemma 2.3.** Given $\varepsilon > 0$, there exists a $W^{2,p}$-viscosity solution $u_\varepsilon$ to

$$
\begin{cases}
F(D^2 u(x)) = f^\varepsilon_u(x) & \text{in} \ \Omega, \\
u = \psi & \text{on} \ \partial \Omega.
\end{cases}
$$

**Proof.** The existence is proved, as we remarked, using the fixed point Theorem A.2. We define $T : \text{Lip}(\Omega) \rightarrow \text{Lip}(\Omega)$ as the application defined by (2.2) and the existence and uniqueness theorem, i.e., $T(v) = u$. In order to prove the hypothesis required for $T$, we will make use of the convergence Theorem A.3.

**Continuity of $T$:** If we consider $v_k \xrightarrow{\text{Lip}} v$, then does $u_k := T(v_k) \xrightarrow{\text{Lip}} T(v)$?

We know that $u_k \in W^{2,p}(\Omega)$ and

$$
\|u_k\|_{W^{2,p}(\Omega)} \leq C \left[ \|u_k\|_{L^\infty(\Omega)} + \|\psi\|_{W^{2,p}(\Omega)} + \|f^\varepsilon_u\|_{L^p(\Omega)} \right] \leq \tilde{C}
$$

with $\tilde{C}$ independent of $k$. This is achieved using Alexandroff-Bakelman-Pucci (ABP) estimates

$$
\sup_{\Omega} u_k \leq \sup_{\partial \Omega} u_k + C \|f^\varepsilon_u\|_{L^p(\Omega)}
$$

and the equivalent for the inf $u_k$. This ABP version for measurable ingredients is stated in Caffarelli-Crandall-Kocan-Swiech (proposition 3.3 in [2]). We also have the estimate

$$
\|f^\varepsilon_u\|_{L^p(\Omega)} \leq |\Omega|^{1/p} g(|\Omega|),
$$

which makes $\tilde{C}$ even independent of $\varepsilon$. Now consider $u_{kj}$ any subsequence of $u_k$. Using the Rellich-Kondrachov theorem, we can find a subsequence $u_{kj_i}$ of $u_{kj}$ (for simplicity we will use the notation $u_i := u_{kj_i}$) converging to some $\bar{u}_\varepsilon$ in the Lipschitz norm, i.e.,

$$
u_i \xrightarrow{\text{Lip}} \bar{u}_\varepsilon.
$$
If we can prove that \( u_\varepsilon \) is the unique \( W^{2,p} \)-viscosity solution to (2.2) \( (v) = u_\varepsilon \),
then we have the convergence \( u_k = T(v_k) \xrightarrow{\text{Lip}} u_\varepsilon = T(v) \). Therefore, we obtain
the continuity for \( T \).

Every \( u_i \in C^0(\Omega) \) is the unique \( W^{2,p} \)-viscosity solution to (2.2) with \( v_i \) in the
right-hand side. We have \( \Omega_i = \Omega \), and \( F_i = F \) fixed for every \( i \). The convergence
\( u_i \xrightarrow{\text{Lip}} u_\varepsilon \)
implies the locally uniformly convergence. So we only need to check the convergence
\[
|f_{v_i}^e(x) - f_{v_j}^e(x)|_{L^p(B_r(x_0))} \xrightarrow{\text{Lip}} 0
\]
in order to satisfy all the hypotheses in the convergence Theorem A.3. We know
that \( v_i \xrightarrow{\text{Lip}} v \), then \( \delta_i := |v_i - v| \xrightarrow{L^\infty} 0 \). Thus, letting \( x \) and \( h \) be fixed,
\[
|v_i \geq v_i(x) - h| \leq |v + \delta_i \geq v(x) - \delta_i - h| \xrightarrow{\nabla} |v \geq v(x) - h|
\]
as \( i \rightarrow \infty \) and also
\[
|v_i \geq v_i(x) - h| \geq |v - \delta_i \geq v(x) + \delta_i - h| \xrightarrow{\nabla} |v \geq v(x) - h|.
\]
We can show that \( |v \geq v(x) - h| = |v \geq v(x) - h| \) for a.e. \( h \in [0;\varepsilon] \). This
happens if and only if \( |v = v(x) - h| = |v^{-1}(v(x) - h)| = 0 \) for a.e. \( h \in [0;\varepsilon] \).
A corollary of the Rademacher theorem says that if \( v \) is a Lipschitz function, then
for a.e. \( y \in v^{-1}(\alpha), \nabla v(y) = 0 \). Therefore
\[
|v^{-1}(v(x) - h)| = |v^{-1}(v(x) - h) \cap \{\nabla v(y) = 0\}|.
\]
Using a corollary of the coarea formula, we also get that
\[
\mathcal{H}^{n-1}(v^{-1}(v(x) - h) \cap \{\nabla v(y) = 0\}) = 0.
\]
Here \( \mathcal{H}^{n-1} \) stands for the \((n - 1)\)-dimensional Hausdorff measure. Then for every
\( x \in \Omega \) we get the convergence
\[
|v_i \geq v_i(x) - h| \xrightarrow{\nabla} |v \geq v(x) - h|
\]
for a.e. \( h \). Applying the dominated convergence theorem first and the continuity of \( g \), we get
\[
(2.4) \qquad g \left( \frac{1}{\varepsilon} \int_0^\varepsilon |v_i \geq v_i(x) - h|dh \right) \xrightarrow{\text{Lip}} g \left( \frac{1}{\varepsilon} \int_0^\varepsilon |v \geq v(x) - h|dh \right)
\]
as \( i \rightarrow \infty \). This last result is the pointwise convergence of \( f_{v_i}^e \) to \( f_v^e \). Again, applying
the dominated convergence theorem, we get the \( L^p \) convergence needed. So all
the hypotheses are satisfied to apply the theorem and therefore \( T \) is continuous.

**Compactness of \( T \):** Let \( v_k \) be a bounded sequence in \( \text{Lip}(\Omega) \). Then \( u_k := T(v_k) \in W^{2,p}(\Omega) \) is bounded as before. After Rellich-Kondrachov there exists a
convergent subsequence.
**Boundedness of the eigenvectors:** We have to prove that the set
\[
\Gamma := \{ v \in \text{Lip}(\Omega) : \exists \gamma \in [0; 1] \text{ such that } v = \gamma T(v) \}
\]
is bounded. Suppose by contradiction that it is not. First we note that \(0 \in \Gamma\) with \(\gamma = 0\), and for every \(0 \neq v \in \Gamma\) the \(\gamma\) associated with \(v\) is not zero. Suppose then that there exists a sequence of nonzero elements \(v_k \in \Gamma\), and a respective sequence \(\gamma_k\) such that \(v_k = \gamma_k T(v_k)\) and \(\|v_k\|_{\text{Lip}(\Omega)} \to \infty\). Because \(v_k \in \text{Lip}(\Omega)\), then
\[
\|v_k\|_{\text{Lip}(\Omega)} \leq \frac{\|v_k\|}{\gamma_k} \leq C \|v_k\|_{W^{2,p}(\Omega)} \leq \tilde{C},
\]
which is a contradiction. Therefore \(\Gamma\) is bounded.

The hypotheses of Schaefer’s theorem are satisfied, so there exists a Lipschitz fixed point \(u_e\) for \(T\), i.e., \(u_e = T(u_e)\). Moreover, by Theorem [A.1], \(u_e\) is a \(W^{2,p}\)-viscosity solution to (2.3), which is in \(W^{2,p}(\Omega)\).

The purpose of finding such a \(u_e\) was to approximate a solution for (0.1). Then the following question is whether we can take the limit \(\varepsilon \to \infty\).

**Proof of Theorem 2.1**

For every \(\varepsilon > 0\) we have a solution \(u_e \in W^{2,p}(\Omega)\) with uniformly bounded \(W^{2,p}\) norm (with respect to \(\varepsilon\)). Then there exists a subsequence (that we will also call \(u_e\)) and a Lipschitz function \(u\) such that
\[
\frac{u_e}{L_{\text{Lip}}(\Omega)} \to u.
\]

So \(u_e \to u\) locally uniformly and we will be able to apply again the convergence Theorem [A.3]. In this case we have on the right-hand sides, the \(L^p\) functions
\[
f_u(x) := g(|u \geq u(x)|) \quad \text{and} \quad f_{u_e}^\varepsilon(x) := g \left( \frac{1}{\varepsilon} \int_0^\varepsilon |u \geq u_e(x) - h| dh \right).
\]

We are left to prove the convergence
\[
\|f_u - f_{u_e}^\varepsilon(x)\|_{L^p(B_r(x_0))} \to 0.
\]

By the triangle inequality
\[
\|f_u - f_{u_e}^\varepsilon(x)\|_{L^p(\Omega)} \leq \|f_u - f_{u_e}^\varepsilon(x)\|_{L^p(\Omega)} + \|f_{u_e}^\varepsilon - f_{u_e}^\varepsilon(x)\|_{L^p(\Omega)}.
\]

We have that the second term goes to zero as in previous calculations (2.4). We will use a similar argument for bounding the first term.

\[
|u \geq u(x)| \leq |u \geq u(x) - h| = |u \geq u(x)| + |u(x) > u \geq u(x) - h| \\
\leq |u \geq u(x)| + |u(x) > u \geq u(x) - \varepsilon|.
\]

Then
\[
\frac{1}{\varepsilon} \int_0^\varepsilon |u \geq u(x) - h| dh \geq \frac{1}{\varepsilon} \int_0^\varepsilon |u \geq u(x)| dh \\
= |u \geq u(x)|
\]
and
\[
\frac{1}{\varepsilon} \int_0^\varepsilon |u \geq u(x) - h|dh \leq \frac{1}{\varepsilon} \int_0^\varepsilon |u \geq u(x)| + |u(x) > u \geq u(x) - \varepsilon|dh \\
= |u \geq u(x)| + |u(x) > u \geq u(x) - \varepsilon|.
\]

Therefore
\[
\frac{1}{\varepsilon} \int_0^\varepsilon |u \geq u(x) - h|dh \nrightarrow |u \geq u(x)|
\]
as \(\varepsilon \to \infty\). Accordingly, we obtained pointwise convergence for \(f^\varepsilon_u\) to \(f_u\), which after the dominated convergence theorem implies the convergence on the \(L^p\) norm.

The hypotheses of Theorem A.3 are satisfied, and we finally obtain our main result: \(u\) a \(W^{2,p}\)-viscosity solution to (0.1), in \(W^{2,p}(\Omega)\) and with the corresponding estimates. \(\square\)

The last remark of this section is that we obtain an explicit formula for the 0 Dirichlet problem in a ball.

**Example 2.4.** When \(\Omega = B_r(x_0)\), \(F = \Delta\), \(g(t) = -t\), and \(\psi = 0\), we have the solution
\[
\tilde{u}(x) = \frac{\omega_n}{2n(n+2)}[r^{n+2} - |x - x_0|^{n+2}],
\]
where \(\omega_n\) is the measure of the \(n\)-dimensional unit ball. In a similar way we can prove that \(\frac{1}{\lambda}u\) is a solution when \(F = \mathcal{M}^-\) (respectively, \(\frac{1}{\lambda}u\) for \(F = \mathcal{M}^+\)). We will use this example in the next section to build subsolutions that can be used as barriers to prove gradient bounds.

### 3 Further Regularity

In order to gain more regularity for our solution \(u\), we probably need to get some regularity for the right-hand side \(f_u\). So far, in the case when \(u\) has flat regions, \(f_u\) is not even continuous. In principle, this discontinuity does not depend on the regularity of \(u\) but on its flat regions. We can prove that under the negativity of \(g\), \(u\) is not allowed to have these flat regions with positive measure.

**Remark 3.1.** Let \(u\) be a solution for (0.1) with right-hand side \(g < 0\) in \((0; |\Omega|)\); then
\[
|u = a| = 0
\]
for every constant \(a \in \mathbb{R}\).

**Proof.** Suppose that there exists an \(a \in \mathbb{R}\) such that \(A := \{u = a\}\) satisfies that \(|A| > 0\). Then, by a classic result from Stampacchia, we obtain that
\[
\nabla u(x) = 0 \quad \text{for a.e. } x \in A.
\]

Now we can define \(A' := A \cap \{\nabla u = 0\}\) and apply Stampacchia’s result again,

(3.1) \(D^2 u(x) = 0 \quad \text{for a.e. } x \in A'\).
We are left with the set $A'' := A' \cap \{ D^2 u = 0 \}$ with the same measure $|A''| = |A'| = |A| > 0$. By the definition of $u$ being a $W^{2,p}$-strong supersolution of (0.1), we have that for a.e. $x$ in $\Omega$

$$F(D^2 u(x)) - g(|u \geq u(x)|) \leq 0.$$ 

Moreover, for $x_0 \in A''$, the argument inside $g$ is strictly positive: $|u \geq u(x_0)| \geq |A''| > 0$. So in the particular case when $g < 0$ in $(0; |\Omega|)$, we get the contradiction

$$F(D^2 u(x_0)) - g(|u \geq u(x_0)|) > 0.$$ 

Then, for this specific case we obtain continuity for $f_u$. But we need at least $C^{0,\alpha}$ regularity on $f_u$ in order to apply Schauder-type estimates to obtain $u \in C^{2,\alpha}$. We will have this regularity in two particular cases listed in the next two theorems. The first one is an adaptation (simplification) of Laurence and Stredulinsky’s theorem and requires an additional lower bound for the gradient.

**Theorem 3.2** (Theorem 3.1 in [6]). Let $u \in W^{2,p}_0(\Omega)$ with a uniform lower bound $|\nabla u| > c_0 > 0$ in the set $\Omega_{t_0} := \{ y \in \Omega : u(y) < t_0 \}$, where $t_0 < \|u\|_{L^\infty}$ and $c_0 = c_0(t_0)$. Then $f_u \in C^1(\Omega_{t_0})$.

In other words, the theorem asserts that if we have an uniform lower bound for the gradient (away from the maximum of $u$), then we get: regularity for the level sets of $u$ and we discard a possible “flatness” that ruins the smoothness of $f_u$. The proof presented in [6] includes an approximation argument by $C^\infty_0$ functions and coarea formula.

This last theorem translates into regularity for our problem. We state this in the following corollary.

**Corollary 3.3.** If we have a solution $u$ to our problem (0.1), with 0 boundary condition and a gradient lower bound as in Theorem 3.2 then $f_u \in C^1(\Omega_{t_0})$, and therefore $u \in C^{2,\alpha}(\Omega_{t_0})$.

**Proof.** In order to get $C^{2,\alpha}$ estimates we just need to apply the classical theory of viscosity solutions for fully nonlinear equations as in chapter 8 from [1]. Recall that at this point we have a right-hand side in $C^1(\Omega_{t_0})$ that allows us to use classical viscosity solutions instead of $W^{2,p}$-viscosity solutions.

The second theorem states that, under certain conditions, a barrier argument implies lower bounds as in Theorem 3.2.

**Theorem 3.4.** If $\Omega$ has a uniform inner ball condition (i.e., for any point $y$ in $\partial \Omega$, there exists a ball $B_\varepsilon \subset \Omega$ with $\varepsilon > \varepsilon_0 > 0$ and $y \in \partial B_\varepsilon$), then $|\nabla u| > c_0 > 0$ in a neighborhood of $\partial \Omega$, where $c_0 = c_0(\|u\|_{C^1,\alpha}(\Omega))$. We consider the case where $g(t) = -t$ and $u = 0$ on $\partial \Omega$.

**Proof.** If we pick any point $y \in \partial \Omega$, we can touch it with a ball $B_{\varepsilon_0} \subset \Omega$. As in Example 2.4, we can build a an explicit solution $\tilde{u}$ in $B_{\varepsilon_0}$ for $F = M^-$. Now
we apply a comparison between \( u \) and \( \tilde{u} \) in order to get gradient estimates. Without loss of generality we can take \( \varepsilon_0 \) small enough such that

\[
|u - u(x)| \geq \frac{1}{2}|\Omega| \geq |B_{\varepsilon_0}|
\]

for every \( x \in B_{\varepsilon_0} \). This is possible because of the continuity of \( u \) and of the right-hand side, i.e.,

\[
|u| \geq t \quad \text{as } t \to 0 \quad |\Omega|.
\]

If this is the case then

\[
\mathcal{M}^{-}(D^2\tilde{u}(x)) = -\{|\tilde{u} \geq u(x)| \cap B_{\varepsilon_0}| \geq \frac{1}{2}|\Omega|
\]

\[
\geq -|u \geq u(x)| = F(D^2u(x)) \geq \mathcal{M}^{-}(D^2u(x))
\]

in \( B_{\varepsilon_0} \). In addition, we have that \( 0 = \tilde{u} \leq u \) at \( \partial B_{\varepsilon_0} \). So comparison applies and forces \( \tilde{u} \leq u \) in \( B_{\varepsilon_0} \). Therefore we also have a lower bound for the gradient at the boundary, with the estimate

\[
|\nabla u| \geq \tilde{u}_{-\nu} = \frac{\omega_n}{2n\Lambda}\varepsilon_0^{n+1} = c_0 > 0
\]

where \(-\nu\) is the inner normal to \( \partial \Omega \). Finally, we can extend a lower bound (say \( c_0/2 \)) to a neighborhood of the boundary of \( \Omega \) that will depend on the \( C^{1,\alpha}(\overline{\Omega}) \) norm of \( u \).

Remark 3.5. We can repeat this argument as long we have uniform inner ball conditions for the level sets \( \{ u = t \} \), and so \( C^{2,\alpha} \) regularity for the solution in that annulus.

Remark 3.6. We expect this condition to be satisfied for convex domains, where we deduce that the solutions will have convex level sets. On the other hand, for nonconvex domains, in particular for dumbbell-shaped domains, we expect to have a singular critical point where the superlevel sets separate into two components.

Appendix

In this appendix we gather the results from the literature that will be used in the proof of the main Theorem 2.1. First we have an existence and uniqueness result when the right-hand side is fixed. We refer to Winter’s version because it includes additional \( W^{2,p} \) bounds for the unique solution.

**Theorem A.1** (Winter 4.6 in [9]). Let \( F \) be a convex operator satisfying the structure condition \( (0.2) \) and \( F(0) = 0 \), \( f \in L^p(\Omega) \) for \( p > n \), \( \psi \in W^{2,p}(\Omega) \), and \( \partial\Omega \subset C^{1,1} \). Then, there exists a unique \( W^{2,p} \) viscosity solution to

\[
\begin{cases}
F(D^2u(x)) = f(x) & \text{in } \Omega, \\
u = \psi & \text{on } \partial\Omega.
\end{cases}
\]
Moreover, \( u \in W^{2,p}(\Omega) \) and 
\[
\|u\|_{W^{2,p}(\Omega)} \leq C[\|u\|_{L^\infty(\Omega)} + \|\psi\|_{W^{2,p}(\Omega)} + \|f\|_{L^p(\Omega)}]
\]
for \( C = C(n, \lambda, \Lambda, p, \Omega) \).

Second, we introduce a classic fixed point theorem that will be crucial to extract a solution to our problem, out of a family of approximations.

**Theorem A.2** (Schaefer fixed point theorem). Let \( T : V \to V \) be a continuous and compact mapping, with \( V \) a Banach space such that the set 
\[
\{v \in V : \exists \gamma \in [0; 1] \text{ such that } v = \gamma T(v)\}
\]
is bounded. Then \( T \) has a fixed point.

Third, we will need the next powerful convergence result that will be used for proving continuity in the fixed point argument and later for proving convergence of the solutions to auxiliary problems.

**Theorem A.3** (Caffarelli-Crandall-Kocan-Swiech 3.8 in [2]). Let \( \Omega_k \subset \Omega_{k+1} \) be a sequence of subdomains of \( \Omega \) converging to \( \Omega \). Let \( F \) and \( F_k \) be uniformly elliptic operators with the same ellipticity constants and satisfying the structure condition (0.2). Let \( f \in L^p(\Omega) \) and \( f_k \in L^p(\Omega_k) \) for \( p > n \). Let \( u_k \in C^0(\Omega_k) \) be \( W^{2,p} \)-viscosity subsolutions (supersolutions) of 
\[
F_k(D^2u(x)) = f_k(x)
\]
in \( \Omega_{k+1} \), with \( u_k \) converging locally uniformly to \( u \) in \( \Omega \). Finally, assume that for every \( B_r(x_0) \subset \Omega \) and for every \( \varphi \in W^{2,p}(B_r(x_0)) \), we have 
\[
\|[(F_k(D^2\varphi(x)) - f_k(x) - F(D^2\varphi(x)) + f(x))]^+\|_{L^p(B_r(x_0))} \to 0,
\]
\[
\|[(F_k(D^2\varphi(x)) - f_k(x) - F(D^2\varphi(x)) + f(x))]^-\|_{L^p(B_r(x_0))} \to 0.
\]
Then \( u \) is a \( W^{2,p} \)-viscosity subsolution (supersolution) of 
\[
F(D^2u(x)) = f(x)
\]
in \( \Omega \).

Finally, we note the following:

**Remark A.4.** Due to a result by Escauriaza in [3], we can extend \( p \) to the case where \( p > n - \varepsilon_0 \) for some universal \( \varepsilon_0 \) in Theorems A.1 and A.3.
