FoxO3 suppresses Myc-driven lymphomagenesis

CJ Vandenberg1,2, N Motoyama3 and S Cory*1,2

This study demonstrates, for the first time, that loss of a single forkhead box class O (FoxO) transcription factor, can promote lymphomagenesis. Using two different mouse models, we show that FoxO3 has a significant tumour-suppressor function in the context of Myc-driven lymphomagenesis. Loss of FoxO3 significantly accelerated myeloid tumorigenesis in vavP-MYC10 transgenic mice and B lymphomagenesis in Eμ-myc transgenic mice. Tumour analysis indicated that the selective pressure for mutation of the p53 pathway during Eμ-myc lymphomagenesis was not altered. Frank tumours were preceded by elevated macrophage numbers in FoxO31/− vavP-MYC10 mice but, surprisingly, pre-B-cell numbers were relatively normal in healthy young FoxO31/−Eμ-myc mice. In vitro assays revealed enhanced survival capacity of Myc-driven cells lacking FoxO3, but no change in cell cycling was detected. The loss of FoxO3 may also be affecting other tumour-suppressive functions for which FoxO1/4 cannot fully compensate.

Cell Death and Disease (2016) 7, e2046; doi:10.1038/cddis.2015.396; published online 14 January 2016

The evolutionarily conserved forkhead box class O (FoxO) transcription factors have important roles in cellular metabolism, stress tolerance and probably lifespan.1,2 They are key regulators of cell proliferation and survival, a large number of their transcriptional targets being involved in apoptosis,3–5 cell cycle arrest,6,7 DNA repair, oxidative stress resistance and metabolic processes.8–9

Regulation of FoxOs is complex, involving acetylation and ubiquitination as well as phosphorylation (reviewed in Eijkelenboom and Burgering10). Under normal conditions of growth factor signalling, FoxO transcription factors are inactivated through phosphorylation by activated AKT. For FoxO3 this occurs at three conserved residues (Thr-32, Ser-253 and Ser-315), resulting in the export of FoxO3 from the nucleus into the cytoplasm11 and proteasomal degradation.12 During conditions of oxidative stress, nuclear translocation and activation of FoxOs occurs through Jun N-terminal kinase phosphorylation, which overrides growth factor signalling.13

The FoxOs are highly related and to some degree can act redundantly as they bind to the same consensus sequence.14 Of the four mammalian FoxO family members, FoxO1, FoxO3 and FoxO4 are widely expressed,14 whereas FoxO6 is mainly expressed in adult brain tissue.15 In haemopoietic tissues, FoxO1 and FoxO3 are the major FoxOs, with FoxO1 levels highest in lymphoid cells and FoxO3 levels highest in myeloid cells.16

Although FoxO41/− mice do not have an obvious phenotype,17 FoxO61/− mice show impaired memory consolidation18 and deletion of FoxO1 results in defects in embryonic vascular development, resulting in death at embryonic day 10.5.17,19 FoxO3-deficient mice display early onset female infertility because of depletion of ovarian follicles caused by widespread follicular activation.17,20 Aged FoxO31/− mice were found to have reduced numbers of haemopoietic stem cells (HSCs),21 implying that FoxO3 contributes to the maintenance of the HSC pool during aging by reducing oxidative stress.22 FoxO3 primes HSCs for metabolic stress (starvation)-induced autophagy, which is necessary for HSC survival.23

Activation of AKT, and thus inactivation of FoxOs, is frequently observed in a range of cancers,24 raising the possibility that FoxO proteins may serve as tumour suppressors. An early study found that loss of individual FoxOs did not cause cancer predisposition, except for loss of FoxO1.17,20 When FoxO1 was deleted using Mx-Cre (at 4 weeks of age), mice developed systemic hemangiomas, but with long latency and low frequency.25 However, compound somatic deletion of three FoxOs, FoxO1/3/4, resulted in thymic lymphomagenesis.26 Furthermore, a dominant-negative FoxO construct, which expresses the conserved DNA-binding domain of FoxO4 but lacks the transactivation domain and thus inhibits the activity of all FoxOs, greatly accelerated the onset of Eμ-myc lymphomas.28 This effect is due, at least in part, to FoxO upregulation of p19ARF expression, which promotes p53-dependent apoptosis. In fact, the dominant-negative FoxO Eμ-myc tumours arose as rapidly as those on a p53−/− background.26 FoxO3 and MYC compete for binding to some promoters and appear to antagonise each other’s activity.27,28 FoxO3 directly regulates expression of the MYC inhibitor MXI1, whereas other Max-interacting protein (MXD) family members are regulated indirectly.30

To determine whether loss of a single FoxO can cooperate in Myc-driven tumorigenesis, we crossed FoxO31/− mice24 with vavP-MYC10 mice, which express the transgene in all haemopoietic lineages and primarily develop myeloid tumours with some T lymphomas,31–33 and with Eμ-myc mice, which

constitutively express Myc in B lymphoid cells and are susceptible to pre-B and B lymphomas.\textsuperscript{33,34}

Results

Loss of FoxO3 accelerates Myc-driven tumorigenesis. vavP-MYC\textsuperscript{10} (hereafter MYC\textsuperscript{10}) transgenic mice develop macrophage tumours with a median onset of approximately 300 days. Lymphomagenesis was significantly accelerated by the loss of FoxO3, all FoxO3\textsuperscript{−/−} MYC\textsuperscript{10} mice having succumbed to disease by 300 days compared with 400 days for the MYC\textsuperscript{10} mice (Figure 1a) (median survival of FoxO3\textsuperscript{−/−} MYC\textsuperscript{10} 256 days versus 295 days for MYC\textsuperscript{10}; \( P < 0.0001 \)).

Comparison of spleen weights and white blood cell (WBC) counts of tumour-bearing mice showed that the tumour burden was higher in the FoxO3\textsuperscript{−/−} MYC\textsuperscript{10} mice (Figures 1b and c). The tumour phenotype (Figure 1d) was comparable between the cohorts, being predominantly monocyte/macrophage tumours (Mac1\textsuperscript{+}F4/80\textsuperscript{+}) with a small proportion of T-cell tumours (Thy1\textsuperscript{+}CD3\textsuperscript{+} and variable CD4 and CD8 expression), as previously reported for MYC\textsuperscript{10} mice.\textsuperscript{32}

When we assessed the impact of FoxO3 loss on lymphomagenesis in E\textsubscript{μ}-myc mice, again we found a significant acceleration in morbidity. The median survival of FoxO3\textsuperscript{−/−} E\textsubscript{μ}-myc mice was 93 versus 125 days for E\textsubscript{μ}-myc mice (\( P < 0.0001 \)), with no FoxO3\textsuperscript{−/−} E\textsubscript{μ}-myc mice surviving beyond 150 days (Figure 2a). Tumour-bearing mice typically presented with enlarged spleen, lymph nodes and/or thymus, with no significant difference in lymphoma burden between genotypes (Figures 2b and c). Although E\textsubscript{μ}-myc mice

**Figure 1** Loss of FoxO3 accelerates Myc-induced myeloid tumorigenesis. (a) Kaplan–Meier survival curves for MYC\textsuperscript{10} (\( n = 32 \), median survival 295 days), FoxO3\textsuperscript{−/−} MYC\textsuperscript{10} (\( n = 35 \), median survival 270 days), FoxO3\textsuperscript{−/−} MYC\textsuperscript{10} (\( n = 33 \), median survival 256 days) and FoxO3\textsuperscript{−/−} (\( n = 24 \)). Non-tumour-related deaths have been censored. Tumorigenesis is significantly accelerated in FoxO3\textsuperscript{−/−} MYC\textsuperscript{10} versus MYC\textsuperscript{10} mice, \( P < 0.0001 \), log-rank test. (b) Spleen weights and (c) WBC counts of sick mice. Leukocytes were elevated in FoxO3\textsuperscript{−/−} MYC\textsuperscript{10} mice, \( **P < 0.01 \), Student’s t-test. (d) Proportions of myeloid and T-cell tumours in sick mice. Tumour cell suspensions were stained for cell surface markers and analysed by FACS. \( n = 22–32 \)
generally succumb to sIgM−B220+ pre-B lymphomas or sIgM+B220+ B-cell lymphomas, certain crosses have led to changes in tumour phenotype, either predominantly B-cell lymphomas (e.g., in p53−/−/Eµ-myc and vavP-Mcl-1/Eµ-myc mice) or a complete change in immunophenotype (e.g., in Eµ-bcl-2/ Eµ-myc and Eµ-v-abl/ Eµ-myc mice). However, immunophenotyping of the FoxO3−/−Eµ-myc lymphomas revealed no major difference in the proportion of pre-B versus B-cell tumours compared with Eµ-myc lymphomas (Figure 2d).

Figure 2 Loss of FoxO3 accelerates Myc-induced lymphomagenesis. (a) Kaplan–Meier survival curves for Eµ-myc (n = 33, median survival 125 days), FoxO3−/−Eµ-myc (n = 59, median survival 101 days) and FoxO3−/−Eµ-myc (n = 23, median survival 93 days). Non-tumour-related deaths have been censored. Lymphomagenesis is significantly accelerated by loss of FoxO3. FoxO3−/−Eµ-myc versus Eµ-myc mice, P < 0.0001; FoxO3−/−Eµ-myc versus Eµ-myc mice, P = 0.0502; FoxO3−/−Eµ-myc versus FoxO3−/−Eµ-myc, P = 0.0076; log-rank test. (b) Spleen weights and (c) WBC counts of sick mice. (d) Proportions of pre-B, mixed (pre-B/B), B and other lymphoid (T or primitive) tumours in sick mice; determined by staining for cell surface markers and FACS analysis. n = 20–42.

Haemopoietic homeostasis is perturbed by loss of FoxO3. To determine whether loss of FoxO3 alters the preneoplastic phenotype of MYC10 mice, which could contribute to the enhanced tumorigenesis, we compared the composition of blood and haemopoietic tissues of healthy mice at 8 weeks of age (Figure 3, Supplementary Figure 1 and Supplementary Table 1).

Perhaps surprisingly, loss of FoxO3 alone had a greater impact on haemopoietic homeostasis than expression of the MYC10 transgene, which provokes only a mild preneoplastic phenotype. The FoxO3−/− mice had significantly increased T cells in the spleen and blood, but not in lymph nodes. Herold et al. have also reported an increase in splenic T cells using the same FoxO3−/− mice, although increased T-cell numbers were not observed in an earlier study using a different line. Consistent with previous reports, the FoxO3−/− mice also had increased myeloid cells in the spleen and bone marrow, reduced recirculating B cells in the bone marrow and elevated immature erythroid cells (Ter119+), presumably due to impaired maturation.

In general, the phenotype of FoxO3−/−MYC10 mice resembled that of FoxO3−/− mice. However, in the spleen,
there was an additional increase in the number of T cells in FoxO3−/−MYC10 mice compared with FoxO3+/− mice (Figure 3). Significant increases in myeloid populations were also observed in the blood, spleen and bone marrow, in particular Mac1+Gr1− cells, which were elevated approximately 2- to 2.5-fold in each organ (Figure 3, Supplementary Figure 1). As the majority of tumours arising in the MYC10 mice are Mac1+Gr1−, it is likely that the increase in this population in FoxO3−/−MYC10 mice is a factor in the acceleration of tumour onset.

Haemopoietic analysis of pre-leukaemic FoxO3−/− Eμ-myc mice and littermates was performed at 4 weeks of age (Figure 4, Supplementary Figure 2 and Supplementary Table 2). Loss of FoxO3 resulted in increased myeloid cells in the blood, spleen and bone marrow of Eμ-myc mice, as in MYC10 mice, but no significant differences were seen in T-cell numbers. As Eμ-myc and FoxO3−/− Eμ-myc mice develop pre-B or B-cell lymphomas, the impact of FoxO3 loss on B lymphopoesis was of particular interest. As documented previously,46 young preneoplastic Eμ-myc mice had a greatly expanded pre-B-cell (B220+IgM−IgD−) population, with 15- to 20-fold increases in the spleen, blood and lymph nodes, and there was a modest further increase in the blood of FoxO3−/− Eμ-myc mice.

**Figure 3** Loss of FoxO3 increases myeloid and T-cell populations in MYC10 mice. Enumeration of total leukocytes and indicated populations in the spleen of preneoplastic 8-week-old male mice (n=8–9 per genotype). Bars represent mean ± S.E.M.; statistical significance is shown only for WT versus FoxO3−/−, MYC10 versus FoxO3−/− MYC10 and FoxO3−/− versus FoxO3−/− MYC10 (*P<0.05, **P<0.01, ***P<0.001, Student’s t-test). See also Supplementary Table S1 and Supplementary Figure 1.

Cell cycle analysis. Deregulation of c-myc promotes tumorigenesis through altered expression of genes regulating cell cycling and proliferation.47 Loss of FoxO may be expected to amplify the cell cycle impact of myc, as FoxO3 regulates genes that promote cell cycle arrest.6,48 We tested this possibility in preneoplastic populations, to avoid the complication of additional oncogenic mutations.

As the MYC10 and FoxO3−/− MYC10 mice are predisposed to myeloid tumours, we analysed the cell cycle profiles of bone marrow macrophages and granulocytes from healthy young mice. No differences in the cell cycle distribution were detectable in either Mac1+Gr1− or Mac1−Gr1+ cells (Figure 5).

For the Eμ-myc and FoxO3−/− Eμ-myc mice, preneoplastic pre-B cells were analysed immediately after isolation from the bone marrow and also during culture in simple medium lacking exogenous cytokines. However, there was no difference between Eμ-myc and FoxO3−/− Eμ-myc pre-B-cell cycle profiles either before culture (first panel, Figure 6a) or at any of the time points analysed (4 h, 8 h, 24 h; Figure 6a). Furthermore, tumour cells isolated from Eμ-myc and FoxO3−/− Eμ-myc mice had similar cell cycle profiles (Figure 6b).

**Impact of loss of FoxO3 on apoptosis of Myc-overexpressing cells.** The proliferative effect of Myc overexpression is partially counteracted by Myc-driven apoptosis.49,50 We therefore investigated whether loss of FoxO3 inhibited apoptosis of cells overexpressing Myc. We reasoned that the impact of loss of FoxO3 may become more apparent during culture, as the deficiency in cytokine signalling would normally inactivate AKT and activate FoxO3.

As expression of the vavP-MYC transgene is highest in thymocytes,32 we isolated the four major thymocyte populations by flow cytometry from wild-type (WT), FoxO3−/−, MYC10 and FoxO3−/− MYC10 mice and cultured them in simple medium (i.e., in the absence of cytokines) either immediately (Supplementary Figure 3A) or following exposure to 1.25 Gy γ-irradiation (Supplementary Figure 3B). For double-positive thymocytes, the most sensitive population,
there was a trend toward an increased viability of FoxO3−/− compared with WT cells under these conditions, but this was not apparent on the MYC10 background. Loss of FoxO3 also enhanced the survival of peripheral T-cell blasts following removal of interleukin 2 (IL-2), as noted previously, 39 and this was evident even in the face of expression of the MYC10 transgene (Supplementary Figure 3C).

Apoptosis was also assessed for B lymphoid cells from Eμ−myc and FoxO3−/−Eμ−myc mice. Frank tumours had comparable numbers of apoptotic cells (Figure 7a and Supplementary Figure 4). When pre-leukaemic pre-B cells sorted from bone marrow were cultured in the absence of cytokines, no significant survival advantage could be detected for those lacking FoxO3 (Figure 7b). However, when IL-7 was removed from IL-7-supported cultures of pre-B cells, loss of FoxO3 significantly enhanced the survival of Eμ−myc (but not WT) pre-B cells (Figure 7c). As IL-7 has a critical role in early B lymphopoiesis, this protective effect may account for the modest increase in pre-B cells in FoxO3−/−Eμ−myc compared with Eμ−myc mice (Figure 4, Supplementary Table 2).

Loss of FoxO3 does not select against inactivation of the p53 pathway. Lymphomas arising in Eμ−myc mice commonly bear mutations that inactivate the p19Arf/Mdm2/p53 pathway, either by p53 mutation or deletion, p19Arf deletion, or overexpression of Mdm2. 51 Although expression of dominant-negative FoxO (dnFoxO) reduced selective pressure to inactivate the p19Arf/p53 pathway during lymphomagenesis in Eμ−myc mice, 26 this was not the case for FoxO3−/−Eμ−myc lymphomas (Figure 8). One FoxO3−/−Eμ−myc tumour (# 81) had high levels of p53 and p19Arf, suggestive of a p53 inactivating mutation (as carried by the tumour).
by the positive control, Eμ-myc lymphoma #22). Certain other FoxO3−/−Eμ-myc lymphomas (#322 and #430) had high levels of p19Arf but expressed no p53, apparently because of upregulation of Mdm2. Two, perhaps three, other FoxO3−/−Eμ-myc lymphomas lacking p53 expression had elevated Mdm2 but did not express p19Arf (#124, #240 and perhaps #94), suggestive of p19Arf deletion, as observed previously.51 Thus, overall, 5 or 6 of 13 (38–46%) FoxO3−/−Eμ-myc lymphomas analysed showed evidence of loss of p53 or Arf function, comparable to the 13/25 (52%) reported by Eischen et al.51 Thus, the absence of FoxO3 alone appears insufficient to select against inactivation of the p53 pathway.

Discussion

We have demonstrated, for the first time, that loss of a single FoxO transcription factor, can promote lymphomagenesis. Whereas Paik et al.25 found that complete loss of FoxO activity (both alleles of FoxO1, FoxO3 and FoxO4) is required for lymphomagenesis, we have shown using two different mouse models that loss of FoxO3 alone suffices to accelerate Myc-driven lymphomagenesis. In the absence of FoxO3, myeloid tumours arose more rapidly in vavP-MYC10 mice and pre-B and B lymphomas arose more rapidly in Eμ-myc transgenic mice (Figures 1 and 2). Unsurprisingly, the reduction in tumour latency was not as great as that observed when a dominant-negative FoxO construct was used to inhibit all FoxOs in the Eμ-myc model.25 Deficiency in a single FoxO does not have an observable effect in all tumour models, however, as loss of FoxO3 or FoxO4 does not accelerate or increase the incidence of DMBA-induced tumorigenesis.25

The larger population of myeloid cells in FoxO3-deficient MYC10 mice is likely to be a significant factor contributing to accelerated myeloid tumour formation in this model (Figure 3, Supplementary Figure 1 and Supplementary Table 1). In the Eμ-myc model, expansion of the pre-B-cell pool, although modest, may contribute to accelerated lymphoma development in the absence of FoxO3.

Several factors may contribute to increasing the size of the susceptible populations. The absence of FoxO3 had no discernible impact on the cycling of preneoplastic and neoplastic Eμ-myc pre-B cells. (a) Pre-B cells (B220+slg−) were purified from the bone marrow of 4-week-old Eμ-myc and FoxO3−/−Eμ-myc mice by flow cytometry and cultured without cytokines. Cell cycle analysis was performed using Nicoletti staining at the indicated time points and flow cytometry. Cell cycle phases were determined using the Watson pragmatic model within the flow cytometry data analysis software FlowJo. Bars represent mean ± S.E.M.; n = 4–5 per genotype. (b) Pre-B/B cells were purified from tumours of Eμ-myc and FoxO3−/−Eμ-myc mice using CD19 beads and MACS columns. Cells were fixed then stained with PI/RNase staining solution. Cell cycle populations were analysed by FACS. Bars represent mean ± S.E.M.; n = 5 per genotype.
FoxO3 genotype.

Impact of loss of FoxO3 on the apoptosis of preneoplastic and neoplastic Eµ-µc cells. (a) Quantification of cleaved caspase-3 positive cells in the spleen and lymph node of sick Eµ-µc and FoxO3−/− Eµ-µc mice. For each tumour section (blinded as to the genotype), cleaved caspase-3-positive cells were enumerated from images of three independent fields of view at x200 magnification. Bars represent mean ± S.E.M.; n = 4–6 per genotype. (b) Spontaneous death of FACS purified preneoplastic pre-B cells (B220+slg) from 4-week-old Eµ-µc and FoxO3−/− Eµ-µc mice cultured in simple medium (no cytokines) was assessed by staining with PI and annexin V followed by FACS analysis (n = 5–6 per genotype). Values represent mean ± S.E.M.; n = 3–4 mice for each genotype. (c) Enhanced survival upon IL-7 withdrawal of cultured FoxO3−/− Eµ-µc pre-B cells. Pre-B cells isolated from bone marrow of mice of the indicated genotypes were cultured in the presence of 2% IL-7 supernatant for 5 days. Survival following removal of IL-7 was determined at the indicated time points by flow cytometry, with data normalised to the viability of each culture when IL-7 was withdrawn, day 0. Bars represent mean ± S.E.M.; n = 4–6 per genotype.

Loss of FoxO3 does not relieve the pressure for mutation of the p53 pathway in Eµ-µc lymphomagenesis. Western blot analysis of p53, p19ARF and Mdm2 in the indicated Eµ-µc and FoxO3−/− Eµ-µc lymphomas; Eµ-µc #22 (right-hand lane on each gel), a known p53 mutant cell line, was included as a positive control. MW markers are indicated (koa). High expression of p19ARF is indicative of p53 mutation (e.g., FoxO3−/− Eµ-µc #B1) or loss (e.g., FoxO3−/− Eµ-µc #322, #430 and Eµ-µc #97). High expression of Mdm2 promotes ubiquitylation and degradation of p53, thereby abrogating p53-mediated apoptosis.

Activation of p53 is a principal route for Myc-induced apoptosis. Myc upregulates p19Arf expression, probably indirectly, and p19Arf binds to and neutralises Mdm2, thereby preventing inhibition and degradation of p53 and facilitating expression of pro-apoptotic p53 targets, BH3-only proteins Puma and Noxa and, in a negative feedback loop, Mdm2.53 Although expression of dnFoxO reduced the selective pressure to inactivate the p19Arf/p53 pathway during lymphomagenesis in Eµ-µc mice,26 this was not the case for FoxO3−/− Eµ-µc lymphomas (Figure 8).

In summary, we have demonstrated using two different mouse models that FoxO3 has a significant tumour-suppressor function in the context of Myc-driven lymphomagenesis. Although our data suggest a role for FoxO3-mediated inhibition of apoptosis in restraining Myc-driven tumour development, we suspect that loss of FoxO3 may also be affecting other tumour-suppressive functions for which FoxO1-/4 cannot fully compensate. Of note, the tumour-suppressive activity of p53 does not involve its capacity to promote apoptosis or cell cycle arrest.54,55
Materials and Methods

Mice. Experimental protocols involving the use of mice were approved by the Walter and Eliza Hall Institute’s Animal Ethics Committee. All mice were on a C57BL/6 background and were bred at the Walter and Eliza Hall Institute (WEHI). To generate FoxO3−/−MYC10 mice, FoxO3−/+ (ref. 21) females were crossed with MYC10tm12mz males (i.e., homozygous for the MYC10 transgene) then offspring were interbred. FoxO3−/−EP-myc mice were produced by mating FoxO3−/− females with EP-myc mice followed by interbreeding of offspring. Analysis was performed on healthy young mice (4 or 8 weeks of age) and cohorts of mice were age-matched to the end point.

Haemopoietic analysis. Blood counts and composition were determined using an ADVIA 2120 haematology analyser (Siemens, Erlangen, Germany). In addition, for preneoplastic analysis, the remaining blood was depleted of red blood cells using 0.168 M ammonium chloride and cell composition determined by flow cytometry, as below. Single-cell suspensions were prepared from spleen, thymus, lymph nodes (axillary, brachial, inguinal) and bone marrow and leukocytes enumerated with a CASY Cell Counter (Scharfe System GmbH, Reutlingen, Germany). Cell composition was determined by staining with fluorochrome-labelled surface marker-specific monoclonal antibodies followed by fluorescence-activated cell sorting (FACS) analysis using an LSR (BD Biosciences, Franklin Lakes, NJ, USA). Data were processed using FlowJo Version 9.3.2 (TreeStar, Ashland, OR, USA). The monoclonal antibodies, produced and labelled with fluorescein isothiocyanate (FITC), R-phycocerythrin or allophycocyanin at WEHI, were: RB6-8C5, anti-Gr1; M1/70, anti-Mac1; H129.19, anti-CD4; YTS169, anti-CD8; Ter119, anti-erythroid marker; RA3-2B8, anti-CD45R-B220; 5.1, anti- IgM; 11-26C, anti-IgD; T24-31, anti-Thy1.

Cell cycle analysis. Pre-B cells (B220+IgM+IgD−) were purified from the bone marrow of 4-week-old mice by flow cytometry, or by using CD19 MicroBeads (Miltenyi Biotech, Bergisch Gladbach, Germany) and MS columns (Miltenyi Biotech) according to the manufacturer’s protocols. The Nicoletti assay26 was used for cell cycle analysis of the purified pre-B cells – cells were resuspended in 0.1% sodium citrate, 0.1% Triton X and 50 μM μl pipidium iodide (PI) and incubated for 30 min on ice before FACS analysis. Alternatively, mixed cell populations, such as bone marrow, were stained with surface markers for the population of interest before fixation and permeabilisation with the Transfection Factor Staining Buffer Set (eBioscience, San Diego, CA, USA). Cells were then stained with PI/RNase staining solution (Cell Signaling Technology, Danvers, MA, USA) for 30 min before analysis on an LSR II flow cytometer (BD Biosciences). Cell cycle profiles were characterised using FlowJo using the Watson pragmatic model (see above).

Survival assays. Thymocyte populations or pre-B cells isolated by flow cytometry were cultured at 0.2–0.5×10^6 cells/ml in high-glucose Dulbecco’s Modified Eagle’s medium supplemented with 10% foetal calf serum (JRH Biosciences, Brooklyn, VIC, Australia); 50 μM 2-mercaptoethanol; 2-ME, Sigma-Aldrich, St Louis, MO, USA) and 100 μg asparagine (Sigma-Aldrich) without additional cytokines. In addition, thymocytes were treated before culture with 1.25 Gy γ-irradiation. Cell viability was determined by staining with FITC-conjugated annexin V and PI followed by flow cytometry. Specific viability was calculated at each time point as (viability of treated cells/viability of untreated cells) x 100%.

Cytokine withdrawal. Pre-B cells (B220+IgM+IgD−) purified from bone marrow by flow cytometry were cultured at a starting density of 1×10^6/ml in Iscove’s modified Dulbecco’s medium supplemented with 1× GlutaMAX, 1 mM sodium pyruvate, 0.1 mM nonessential amino acids, 10 mM HEPES pH 7.4 (all media supplements from Life Technologies, Carlsbad, CA, USA); 50 μM 2-ME; 10% foetal calf serum and 2% IL-7 supernatant (produced by transfected x63/0 hybridoma calves).57 Cultures were split if required. After 5 days, cells were washed three times to remove IL-7, then replated at 0.3×10^6/ml with or without IL-7 for 2 days. Viability was determined by flow cytometry as above.

T-cell blasts were generated by stimulation of splenocytes (2×10^6/ml) for 3 days with 1% IL-2 supernatant57 and 2 μg/ml concanavalin A (Sigma-Aldrich) in cell culture medium as for survival assays above. Cells were then washed three times to remove concanavalin A and cultured with IL-2 alone for 24 h. To set up the death assay, cells were washed three times to remove IL-2 then cultured with or without IL-2 for 2 days. Viability was determined by flow cytometry as above.

Cleaved caspase-3 immunohistochemistry. Splenies and lymph nodes from lymphoma-bearing mice were fixed in 10% formalin then embedded in paraffin. Sections were stained for cleaved caspase-3 using the SignalStain Apoptosis (Cleaved Caspase-3) IHC Detection Kit (Cell Signaling Technology) according to the manufacturer’s protocols. Stained slides were imaged (blinded as to genotype) using an Olympus BX43 microscope (Olympus, Tokyo, Japan) and Olympus DP72 camera at x200 magnification.

Immunoblotting. Protein extracts were prepared by lysis in RIPA buffer (300 mM NaCl, 2% IGEPL, 0.5% SDS, 10 mM Tris-HCl pH 8.0) containing complete ULTRA protease inhibitors (Roche, Basel, Switzerland). Western blots were carried out using 30 μg total protein per sample run on NuPAGE Bis-Tris gels (Life Technologies) and transferred to nitrocellulose membranes with an iBlot (Life Technologies) according to the manufacturer’s protocols. Blots were probed with the following antibodies: p53 (FL-393, Santa Cruz Biotechnology, Santa Cruz, CA, USA); p19ARF (p19ARF exon 2, Rockland, Gilbertsville, PA, USA); Mdm2 (C-18, Santa Cruz Biotechnology); FoxO3 (75D8, Cell Signaling Technology); FoxO1 (C29H4, Cell Signaling Technology); and b-actin (clone AC-74, Sigma-Aldrich).

Statistical analysis. GraphPad Prism (Version 6.0d, GraphPad Software, San Diego, CA, USA) was used to graph and statistically analyse data. Student’s t-test (an unpaired two-tailed t-test) or the log-rank (Mantel–Cox) test, for Kaplan–Meier mouse survival curves, were used to determine statistical significance.

Acknowledgements. We thank our institute colleagues A Strasser, MJ Herold and Steve Nutt for useful discussions; J Mansheim, K Hughes, S Allan, M Robati and J Corbin for excellent technical assistance; and the institute’s Flow Cytometry Facility for skilled support. This work was supported by the NHMRC (Australia) program grants 461221; 1016647; NCI grant CA43540; Leukemia and Lymphoma Society (CJV); and infrastructure support to WEHI from the NHMRC Independent Research Institute Infrastructure Support Scheme (OIS) and the Victorian State Government Operational Infrastructure Support (OIS).

Author contributions

CJV and SC conceived the studies, planned experiments, analysed data and wrote the manuscript. CJV performed the experiments. NM provided mice and intellectual input.
