Molecular hydrogen regulates gene expression by modifying the free radical chain reaction-dependent generation of oxidized phospholipid mediators

Katsuya Iuchi1,*, Akemi Imoto1,†, Naomi Kamimura1,*, Kiyomi Nishimaki1,*, Harumi Ichimiya1, Takashi Yokota1 & Shigeo Ohta1,2

We previously showed that H2 acts as a novel antioxidant to protect cells against oxidative stress. Subsequently, numerous studies have indicated the potential applications of H2 in therapeutic and preventive medicine. Moreover, H2 regulates various signal transduction pathways and the expression of many genes. However, the primary targets of H2 in the signal transduction pathways are unknown. Here, we attempted to determine how H2 regulates gene expression. In a pure chemical system, H2 gas (approximately 1%, v/v) suppressed the autoxidation of linoleic acid that proceeds by a free radical chain reaction, and pure 1-palmitoyl-2-arachidonyl-sn-glycero-3-phosphocholine (PAPC), one of the major phospholipids, was autoxidized in the presence or absence of H2. H2 modified the chemical production of the autoxidized phospholipid species in the cell-free system. Exposure of cultured cells to the H2-dependently autoxidized phospholipid species reduced Ca2+ signal transduction and mediated the expression of various genes as revealed by comprehensive microarray analysis. In the cultured cells, H2 suppressed free radical chain reaction-dependent peroxidation and recovered the increased cellular Ca2+, resulting in the regulation of Ca2+-dependent gene expression. Thus, H2 might regulate gene expression via the Ca2+ signal transduction pathway by modifying the free radical-dependent generation of oxidized phospholipid mediators.

Molecular hydrogen (H2) was originally thought to behave as an inert gas in mammalian cells; however, our previous studies showed that this is not always the case1, demonstrating that H2 neutralizes the hydroxyl radical (·OH) and peroxynitrite (ONOO−) inside cells and acts as a novel antioxidant to protect the cells against oxidative stress1,2. Inhalation of 1%–4% (v/v) H2 gas is effective for the treatment of ischemia/reperfusion injuries1,3,4. Recently, inhalation of 1.3% H2 gas from a premixed gas was shown to protect neurons in a cardiac arrest model5. However, the mechanism of how such a low concentration of H2 exerts the positive effects is not known.

Numerous studies have strongly suggested that H2 has the potential for a variety of therapeutic and preventive applications6–7. In addition to extensive animal experiments, more than 10 clinical studies examining the efficacy of H2 have been reported6–7, including double-blinded clinical studies in patients with Parkinson’s disease and rheumatism6,8. Based on these studies, the field of hydrogen medicine is rapidly growing.

Subsequently, H2 was shown to exhibit multiple functions, including anti-inflammatory, anti-apoptotic, anti-allergic, and antioxidant activities, as well as regulation of differentiation and energy metabolism6–7. To exert multiple functions in addition to anti-oxidative roles, H2 regulates various signal transduction pathways and the expression of many genes6–7. For examples, H2 protects neural cells and stimulates energy metabolism by

stimulating the hormonal expression of ghrelin\(^{19}\) and fibroblast growth factor 21 (FGF21)\(^{14,15}\), respectively. In contrast, \(\text{H}_2\) relieves inflammation by decreasing pro-inflammatory cytokines\(^{12}\). However, it is difficult to explain the molecular mechanisms by which \(\text{H}_2\) exerts these functions by conventional concepts alone. To understand the molecular mechanisms by which \(\text{H}_2\) exerts these multiple functions, it is essential to identify the primary targets of \(\text{H}_2\) that modulate signal transduction and gene expression.

Therefore, in this study, we aimed to elucidate one of the molecular mechanisms by which \(\text{H}_2\) mediates signal transduction and gene expression. Our results suggested that low concentrations of \(\text{H}_2\) modulated \(\text{Ca}^{2+}\) signal transduction and regulated gene expression by modifying the production of oxidized phospholipid species.

Results

\(\text{H}_2\) accumulated in the lipid phases. To understand the difference between intracellular conditions and aqueous solutions, we focused on the lipid phases to determine the intracellular localization of \(\text{H}_2\) accumulation at room temperature. \(\text{H}_2\) incorporation was two- or three-fold higher in the liquid fatty acid phases than in the aqueous phase in the presence of both water and fatty acids, and was retained longer in the fatty acid phases than in the aqueous phase in open vessels (Fig. 1a,b). In particular, \(\text{H}_2\) seemed to be retained significantly longer in the unsaturated fatty acid (linolenic acid) than in the saturated fatty acids (octanoic acid) (Fig. 1c), although this difference in retention time might be attributed to the difference in the number of carbons. Since unsaturated fatty acids are the primary targets for initiating a free radical chain reaction, we assumed that \(\text{H}_2\) could efficiently suppress this reaction in biomembranes, even at low concentrations.

Autoxidation of unsaturated fatty acids was suppressed by low concentrations of \(\text{H}_2\) gas. Autoxidation of unsaturated fatty acids proceeds by a free radical chain reaction in air\(^{13}\). Thus, we measured autoxidation of a filmy di-unsaturated fatty acid (linoleic acid: \(\text{R}-\text{CH}=\text{CH}-\text{CH}=\text{C}(-\text{R'})\) at 37 °C for 20 h in the dark in the presence of various concentrations of \(\text{H}_2\) gas. A conjugated diene, which should be formed by autoxidation, was estimated by the absorption at 234 nm (Fig. 2a). The absorption at 234 nm was increased depending on the formation of the conjugated diene \([\text{R}-\text{CH}=\text{CH}=\text{CH}=\text{C}(-\text{R'})]\) accompanied by peroxidation in a pure chemical system (\(\text{H}_2\), \(\text{O}_2\), and \(\text{N}_2\) were supplied from gas cylinders) (Fig. 2b). \(\text{O}_2\) was essential for autoxidation (Fig. 2c). As a result, even only approximately 1% \(\text{H}_2\) gas significantly suppressed autoxidation of linoleic acid at 37 °C, even in the absence of any catalysts in the dark in a pure chemical system (Fig. 2c).

\(\text{Ca}^{2+}\) signal transduction by \(\text{H}_2\)-dependent chemical oxidation of phospholipids. Phospholipids are converted into oxidized mediators that modulate various signal transduction pathways by not only enzymatic reactions, but also by chemical oxidation\(^{14,15}\). Oxidized phospholipids, including \(1\)-palmitoyl-2-(5-oxovaleroyl)-\(sn\)-glycero-3-phosphocholine (POVPC) and \(1\)-palmitoyl-2-glutaroyl-\(sn\)-glycero-3-phosphocholine (PGPC), are present in oxidatively modified low-density lipoproteins (oxLDLs) and have been found in atherosclerotic lesions\(^{15}\). These compounds are important as inducers of different cellular responses, including inflammation, proliferation, and cell death. Moreover, autoxidation of \(1\)-palmitoyl-2-archachidonyl-\(sn\)-glycero-3-phosphocholine (PAPC) leads to the chemical production of various bioactive phospholipid species, such as POVPC, PGPC, \(1\)-palmitoyl-2-(5-hydroxy-8-oxo-6-enoyl)-\(sn\)-glycero-3-phosphocholine (\(\text{HOOA-PC}\)), and 5-hydroxy-8-oxo-6-oxo-6-octenedioic acid (\(\text{HOdiA-PC}\))\(^{14,15}\).

We assumed that low concentrations of \(\text{H}_2\) would influence some chemical reactions leading to the production of putative oxidized lipid mediators for the modulation of signal transduction. Because PAPC is one of the major phospholipids in mammalian biomembranes, the role of \(\text{H}_2\) in the chemical production of oxidized phospholipid...
Comprehensive analysis of H2-dependent regulation of gene expression. Next, we investigated how H2OxPAPC influences gene expression. PAPC was autoxidized in the absence or presence of various concentrations of H2 for 3 days and then administered to cultured THP-1 cells. In a preliminary experiment, the change in the expression level of tumor necrosis factor (TNF-α) was investigated to compare to those of PAPC. Next, the expression of transcription factors involved in Ca2+ signaling16 and the notation of H2[x%]OxPAPC was used when autoxidized in the presence of x% H2. H2 suppressed the generation of total peroxides as revealed by Liperfluo fluorescence intensity (Fig. 3d). Ca2+ signaling was observed when PAPC was autoxidized with less than 0.3% H2, whereas more than 1.3% H2 significantly disrupted this signaling (Fig. 3e).

In order to investigate the molecule(s) influenced by H2, we analyzed H2OxPAPCs by using mass spectrometry on autoxidation day 3. In all, 209 bands were detected, with molecular masses ranging from 126.3754 to 991.6494 Da. This was consistent with the findings of a previous report15 (Supplementary Fig. 1). The differences in the production of H2OxPAPC and OxPAPC species were presented using a heat map (Supplementary Fig. 1i). The levels of many bands were increased or decreased with differences in concentrations of H2. For examples as the relatively increased species, the levels of the Ca2+ signaling inducers POVPC16, HOOA-PC, HOdiA-PC, and hydroxyeicosatetraenoic acid-3-phosphocholine (HETE-PC)17 were slightly increased in response to H2. For example, the heat map showed that H2OxPAPCs were produced in an oxidation time-dependent manner (Fig. 3c).

Because the reduced form of POVPC was reported to function as an antagonist18, it is possible that increased levels of the reduced form(s) of some OxPAPC species, rather than the decreased levels of putative agonists (such as POVPC), might have disrupted Ca2+ signaling as a putative antagonist(s). Further studies are warranted to identify the H2-dependent bioactive mediator(s).

Figure 2. Suppression of autoxidation of linoleic acid-film by H2 gas. (a) Profile of ultraviolet absorption of 9-hydroxyoctadecadienoic acid; CH(H2)4-CH = CH-CH = CH-CH(-OH)-(CH3)7-COOH) (9-HODE) in cyclohexane, shown as a standard conjugated diene. (b) Linoleic acid-film was autoxidized at 37 °C for 20 h in a glass tube placed in a closed aluminum bag in the presence of various concentrations of H2 and O2 as described in Methods. Representative profiles of ultraviolet absorption of the cyclohexane solution of H2-dependent autoxidized linoleic acid are shown. (c) Linoleic acids autoxidized with various concentrations of H2 were evaluated by measuring absorption at 234 nm. *P = 0.034 (0.3% H2), #P = 0.069 (1% H2), **P < 0.01 (3% H2), ***P < 0.001 (80% H2) vs. 0% H2 (n = 15).
classified the 86 selected genes (Fig. 4e, lower). Of these 86 genes, 46.5% belonged to those involved in signaling pathways (Fig. 4d, upper), whereas 25.8% of the total number of 7,143 genes is involved in signaling pathways (Fig. 4d, lower). Genes encoding factors involved in signal transduction and transcription factors are indicated by blue and black, respectively, on the right in the heat map (Fig. 4a).

Among the genes involved in signaling pathways, the proportion of those belonging to Ca\(^{2+}\) signaling were lower in the selected genes than in those in the entire genome, indicating that \(H_2\) regulates fewer components of the Ca\(^{2+}\) signaling pathways (Fig. 4e, lower). This was consistent with the finding that \(H_2\) had decreased Ca\(^{2+}\) signaling. In contrast, the proportion of genes belonging to the mitogen-activate protein kinase (MAPK)
Figure 4. Changes in gene expression regulated by H2OxPAPC. (a) Three samples of PAPC, OxPAPC, and H2OxPAPC were exposed to THP-1 cells for 4 h, and the gene expression was comprehensively analyzed using microarray. Eighty-six genes were selected according to the following criteria; genes up-regulated by OxPAPC (more than 2.5-fold, vs. PAPC) and those down-regulated by H2[1.3%]OxPAPC and H2[5%]OxPAPC (less than 0.75-fold and 0.5-fold, respectively, vs. OxPAPC) are shown in a heat map (red and green indicate the up-regulation vs. PAPC treatment, and the down-regulation vs. OxPAPC treatment, respectively, as shown in the color gradient). Possible target genes of NFAT and CREB are marked with red on the right. Genes encoding factors involved in signal transduction and transcription are indicated by blue and black, respectively, on the right. The release of TNF-α (b) (from THP-1) and IL-8 (c) (from HAEC) was investigated using ELISA as described in Methods. (d, lower) Ratio of genes belonging to each category in the 86 selected genes listed in a. (e, upper) Ratio of genes belonging to each signaling pathway identified by the whole KEGG database. (d, lower) Ratio of genes belonging to each signaling pathway in the selected genes listed in (a). (f) The H2OxPAPC-dependent expression of genes transcribed by CREB and NFAT. Transcription factors are indicated in yellow.
signaling was higher (Fig. 4e, lower), indicating that \( \text{H}_2 \) regulates more components of MAPK signal transduction pathways (Fig. 4e, lower).

The signal transduction pathways that were regulated by \( \text{H}_2 \) are shown in Supplementary Table 1 according to the KEGG Pathway Database. These data suggested the possibility that low concentrations of \( \text{H}_2 \) contribute to various signal transduction pathways via oxidized phospholipid species.

**Free radical inducers contributed to the NFAT pathway in cultured cells.** Autodissociation of unsaturated fatty acids, including PAPC, proceeds by a free radical chain reaction\(^3\), and -OH is the primary trigger for this reaction\(^3\). We previously showed that \( \text{H}_2 \) reduces -OH levels inside cultured cells by using the spin trapping method and a specific fluorescent indicator\(^1\). Thus, in this study, we investigated the effects of \( \text{H}_2 \) on the lipid free radical chain reaction by using cultured cells. To initiate a free radical chain reaction inside the cells, we used 2,2'-azobis(2-methylpropionamidine)dihydrochloride (AAPH)\(^2\), which is not affected by \( \text{H}_2 \) (Supplementary Fig. 4) and is suitable for the slow generation of free radicals by a spontaneous chemical reaction. The lipid free radical chain reaction results in the production of lipid peroxides (LPOs)\(^2\), which can be detected using the fluorescent dye Liperfluo\(^2\). Thus, we exposed cultured THP-1 cells to AAPH and estimated LPO production based on the Liperfluo signal. The Liperfluo signal significantly decreased in the presence of low levels of \( \text{H}_2 \) gas (e.g., 1.3%; Fig. 5a,b). Thus, even at such low concentrations, \( \text{H}_2 \) has the potential to reduce the generation of LPOs by suppressing the initiation and/or propagation of free radical chain reactions in cultured cells.

Next, we determined whether the responses induced by chemically produced \( \text{H}_2 \text{OxPAPC} \) (Figs 3 and 4) could simulate the effects induced by the free radicals in cultured cells. When THP-1 cells were exposed to AAPH, the cellular \( \text{Ca}^{2+} \) levels increased (Fig. 5c) in a time-dependent manner (Fig. 5d), as shown by the analysis of Fluo-3, and the \( \text{Ca}^{2+} \) signaling was suppressed by \( \text{H}_2 \) (Fig. 5c,e). NFAT was also activated, as shown by the translocation of NFAT into the nucleus (Fig. 5f,g), and the nuclear translocation of NFAT were recovered by \( \text{H}_2 \) (Fig. 5f,g). Moreover, the free radical inducer stimulated the expression of some target genes of NFAT, including \( \text{NFATc} \) (NF-κB), early growth response protein 1 (\( \text{EGR1} \)), and activating transcription factor 3 (\( \text{ATF3} \)), which have been shown in Supplementary Table 1, and \( \text{H}_2 \) decreased their expressions (Fig. 5h), suggesting that \( \text{H}_2 \) regulates these genes via NFAT signaling.

In contrast, AAPH-mediated activation of CREB was not observed (Supplementary Fig. 5) in this cultured cell line, regardless of the stimulation of cellular \( \text{Ca}^{2+} \). In particular, the expression of the CREB-target gene \( \text{NFKB2} \) (NF-κB, subunit 2 gene) was not affected by AAPH (Fig. 5i), and the expression of \( \text{HMox1} \) (Heme Oxygenase 1 gene), a nuclear factor-E2-related factor 2 (Nrf2)-target, was slightly but not significantly increased by \( \text{H}_2 \) (Fig. 5i). This result was consistent with those of a previous study\(^2\). Thus, the NFAT pathway could mainly contribute to the \( \text{H}_2 \)-dependent transcriptional response induced by free radicals at least in THP-1 cells.

Taken together, these cellular responses, at least partly, are in agreement with those obtained using the \textit{in vitro} \( \text{H}_2 \)-dependent products of OxPAPC species (Figs 3, 4). Therefore, we proposed a model in which \( \text{H}_2 \) is linked to the modulation of \( \text{Ca}^{2+} \) signal transduction and the NFAT pathway via oxidized phospholipid species, as illustrated in Fig. 6.

**Discussion** While the biological effects of \( \text{H}_2 \) have been evaluated in more than 300 animal studies and 10 clinical analyses in humans\(^5\), the molecular mechanisms by which \( \text{H}_2 \) at low concentrations exerts its multiple effects on signal transduction remained unknown. Therefore, in this study, we aimed to examine how \( \text{H}_2 \) regulates signal transduction pathways that mediate gene expression. Our results suggested that low concentrations of \( \text{H}_2 \) modulated \( \text{Ca}^{2+} \) signal transduction and regulated gene expression by modifying the production of oxidized phospholipid species. Hence, these data provide important insights into one of the molecular mechanisms by which \( \text{H}_2 \) mediates gene expression.

\( \text{H}_2 \) can be ingested via several methods. Drinking of \( \text{H}_2 \)-infused water (\( \text{H}_2 \text{-water} \)) has been shown to be efficacious in the treatment of various diseases in animal models and humans\(^6\); however, \( \text{H}_2 \) can be infused up to only 0.8 mM under atmospheric pressure, and drinking saturated \( \text{H}_2 \)-water provides a blood concentration up to only ~10 μM, with a short dwelling time in the body\(^11\). Moreover, inhaling 1%–4% (v/v) \( \text{H}_2 \) gas was shown to be effective, reaching concentrations of 8–32 μM \( \text{H}_2 \) in the blood\(^13\). However, initiation of cellular signals by these low concentrations of \( \text{H}_2 \) may be difficult to be explained because \( \text{H}_2 \) should be too inert to react with most molecules. To activate \( \text{H}_2 \) for reaction with the other molecules, a sufficient level of a putative catalyst must be present; however, it is unlikely that such a putative catalyst would be abundant inside cells. Moreover, \( \text{H}_2 \) is very small and is unlikely to bind to a putative \( \text{H}_2 \)-binding receptor because its intra-molecular fluctuation would be
Figure 5. H₂ suppressed free radical inducer-dependent fatty acid peroxidation and Ca²⁺ and NFAT signaling. (a) THP-1 was exposed to a free radical inducer (10 mM AAPH) in the absence or presence of the indicated concentrations of H₂ for 4.5 h. Representative flow cytometric profiles are shown to demonstrate lipid peroxides with Liperfluo signals. (b) The Liperfluo signals were quantified. *P = 0.015, **P < 0.001 vs. 0% H₂ (n = 6). (c) THP-1 cells were treated with 10 mM AAPH for 3 h in the presence of the indicated concentrations of H₂. Intracellular Fluo-3 fluorescence intensity was observed using a laser scanning confocal microscope. Scale bar: 50 μm. (d) THP-1 cells were treated with 10 mM AAPH for the indicated periods in the absence of H₂ and then time-dependent increase in Ca²⁺-signal was monitored by intracellular Fluo-3 fluorescence intensity as described in (c). (e) Fluo3-positive cells were semi-quantified after the treatment with 10 mM AAPH for 3 h in the absence or presence of the indicated concentrations of H₂. **P < 0.01 vs. no H₂ (n = 3). (f) THP-1 was
treated with 10 mM AAPH for 3 h in the presence of the indicated concentrations of H₂. The translocation of NFAT into the nucleus was examined as described in Methods and shown by immunostaining in yellow. The nucleus was counter-stained with Hoechst 33342 as shown in blue. Scale bar: 50 μm. (g) The NFAT-expressing areas were semi-quantified and shown by the ratio of NFAT in the nucleus with that in cytosol. *P = 0.023 and **P < 0.01 vs. no H₂ (n = 10). (h,i) The expressions of the NFAT-target genes (TNF-α, EGR1, and ATF3) (h) and non-NFAT target genes (NFKB2 and HMOX1) (i) were estimated using RT-PCR coupled with a TaqMan probe (the probes are listed in Supplementary Table 2). The names of the genes are described in Supplementary Table 1. *P = 0.015 (for ATF3) (+ AAPH and + H₂ vs. + AAPH and –H₂). #P = 0.14 (for HMOX1) (+ AAPH and –H₂ vs. + AAPH and + H₂), and **P < 0.01 (n = 3).

expected to lead to instability in terms of thermodynamics, as previously discussed. Thus, it was unknown how low concentrations of H₂ regulate signal transduction and gene expression.

Since increased oxidative stress involving ·OH triggers free radical chain reactions, we assumed that the chemically produced mediators derived from phospholipids could contribute to various pathogenic conditions. In the present study, we verified that a small amount of H₂ (as low as 1.3%) affected free radical-dependent lipid peroxidation, from which oxidized lipid mediators should be derived.

Generally, H₂ hydrogenates unsaturated fatty acids at higher temperatures with a palladium catalyst. To the best of our knowledge, no studies have examined autoxidation-dependent hydrogenation at approximately 1% (v/v) H₂ gas at 37 °C without any catalysts. Although H₂ was thought to be inert in the absence of a catalyst at body temperature, we demonstrated that approximately 1% (v/v) H₂ suppressed autoxidation of an unsaturated fatty acid in a chemically pure system in this study; thus, our data provided insights into the biological activities of H₂.

There are two possibilities: the effects of oxidized phospholipid species on Ca²⁺ signaling may be explain by decreased levels of a putative agonist that induces Ca²⁺ signaling or by increased levels of a putative antagonist that disturbs Ca²⁺ signaling. Although we could not identify these species in this study, it is likely that H₂ modified the production of reduced forms of oxidized phospholipid species during free radical chain reactions by the following previous findings: POVPc is a bioactive phospholipid-mediator that is produced by chemical oxidation of PAPC, and the reduced form of POVPc has been shown to function as an antagonist for signal transduction. Thus, it is possible that during a lipid free radical chain reaction, H₂ contributes to the generation of a reduced form(s) that function(s) as an antagonist(s). Therefore, we proposed a hypothetic model in which H₂ is linked to the modulation of Ca²⁺ signal transduction and the NFAT pathway via oxidized phospholipid species as illustrated in Fig. 6.

Previous studies have shown that 1%–4% was efficacious in inhaling H₂ gas in various animal experiments. Since a mixed gas containing 1.3% H₂, 30% O₂ and 68.7% N₂ is available, the effects of around 1.3% needed to be investigated in further studies, including clinical ones. The effective concentrations of H₂ gas were approximately consistent throughout this study (Figs 2–5).

No receptors involved in Ca²⁺ signaling were identified in the present study; however, a previous study showed that some chemically oxidized phospholipid mediators, such as 9-HODE and 11-HETE, could bind a G-protein coupled receptor (G2A) to induce Ca²⁺ signaling. Thus, putative oxidized phospholipid mediators or antagonists might bind to G-protein coupled receptors to modulate signal transduction.

In addition to the anti-oxidative roles of H₂, it has shown to function as an immunosuppressant in allotransplantation. This immunosuppressant effect can be explained by the suppression of NFAT activation because an immunosuppressant such as CsA and tacrolimus (FK506) acts through the inactivation of calcineurin. Since pro-inflammatory cytokines are regulated by NFAT-dependent mechanisms, the anti-inflammatory effects by H₂ can be explained by the suppression of NFAT. Additionally, the anti-allergic effects of H₂ can be explained by the decrease in Ca²⁺/NFAT signaling.

A considerable number of the multiple functions of H₂, as shown by previous studies, might be explained by the link between H₂ and NFAT because of the numerous multiple functions of NFAT. For example, decreased expression of inducible nitric oxide synthase (iNOS) by H₂ can be explained by the inactivation of NFAT. The suppression of osteoclast differentiation and improvement of hypertension by H₂ could involve the NFAT pathway. Moreover, the decreased expression of gene products through an NFAT-dependent pathway might be involved in α-synuclein-induced degeneration of midbrain dopaminergic neurons in Parkinson’s disease. This NFAT-dependent pathway might explain the beneficial effects of H₂ in these patients. Further studies are needed to elucidate the mechanisms by which H₂ exerts multiple functions in terms of the involvement of the NFAT pathway.

In summary, in this study, we investigated the link among H₂, oxidized phospholipids, and Ca²⁺ signaling. Further studies are warranted to identify the H₂-dependent bioactive mediator(s). Our data provided important insights into one of the mechanisms by which H₂ regulates signal transduction and gene expression; however, H₂ might contribute to other types of signaling pathways as well because H₂ regulates many genes belonging to various signaling pathways. A more detailed understanding of the molecular mechanisms of H₂-dependent signal transduction and gene expression is expected to facilitate the application of H₂ in a wide range of medical applications.

**Methods**

**Measurement of H₂.** Gases containing H₂ were prepared by mixing H₂, O₂, N₂, and CO₂ at various concentrations from each gas cylinder equipped with a flow meter. The H₂ concentration in the mixed gas or air was tested in each experiment by using gas chromatography (Breath Gas Analyzer, Model TGA2000; TERAMECS Co. Ltd., Kyoto, Japan) as described previously. For the measurement of H₂ in the solvent, H₂ was transferred to the air phase in a closed aluminum bag, and the concentration of H₂ measured by using gas chromatography.
as described previously\(^1\). The aluminum used in the bag was covered with a plastic film to avoid any influence of aluminum.

**Autoxidation of linoleic acid-film.** Linoleic acid and (±)-9-HODE were purchased from Nacalai Tesque (Kyoto, Japan) and CAY (MI, USA), respectively. Linoleic acid was dissolved in cyclohexane to 16 mM, and 2 \( \mu \)L was dispensed into each glass tube (φ10 × 50 mm) that had been filled with argon gas; it was allowed to dry up to form a linoleic acid-film at the bottom of a glass tube. The glass tubes were placed into a closed aluminum bag, and the gas in the bag was completely replaced with the indicated mixed gas, where pure H\(_2\), O\(_2\), and N\(_2\) were obtained from separate cylinders. The bag was incubated at 37 °C for 20 h for the autoxidation, and 0.2 mL cyclohexane was immediately added to the glass tube to obtain 0.16 mM peroxidized linoleic acid. The concentration of conjugated diene was estimated by measuring the absorption at 234 nm while scanning from 200 to 300 nm.

**Autoxidation of pure PAPC in air in the absence or presence of H\(_2\).** Chemically synthesized pure PAPC was purchased from Avanti Polar Lipids (Alabaster, AL, USA). PAPC was autoxidized in air as described previously\(^4\). Briefly, 0.5 mg of PAPC in 50 \( \mu \)L of chloroform was transferred to a φ10 × 50 mm glass tube and dried up under a gentle stream of nitrogen. The lipid residue was allowed to autoxidize in air with 100% humidity at 25 °C in the presence or absence of the indicated concentrations of H\(_2\) gas in a closed aluminum bag for the indicated periods, and then suspended in PBS at a concentration of 0.5 mg/mL.

**Estimation of OxPAPC with Liperfluo.** OxPAPC was assayed in ethanol with Liperfluo as described previously\(^25\). Five min after adding OxPAPC to 1 \( \mu \)M Liperfluo at room temperature, the fluorescence was measured using a fluorescence spectrophotometer (RF-5300PC; Shimadzu Corporation, Kyoto, Japan), where wavelengths of excitation and emission were set at 488 and 535 nm, respectively.

**Measurement of Ca\(^{2+}\) signaling.** Intracellular Ca\(^{2+}\) in THP-1 cells treated with OxPAPC was measured using a Calcium Kit-Fluo 4 (CS22; Dojindo, Kumamoto, Japan) according to the manufacturer's protocol. Briefly, THP-1 cells were washed with PBS and incubated with 4.5 \( \mu \)M Fluo 4-AM in recording medium (20 mM HEPES,
115 mM NaCl, 5.4 mM KCl, 0.8 mM MgCl₂, 1.8 mM CaCl₂, 13.8 mM glucose) containing 0.064% pluronic F-127 and 1.25 mM probenecid for 30 min at 37°C. The cells were washed with PBS and resuspended in recording medium containing 1.25 mM probenecid. The cells were seeded on 35-mm glass-bottomed dishes and then stimulated with 100 µg/mL OxPAPC or H₂OxPAPC, followed by 25 µM ATP. The changes in Fluo-4-AM fluorescence were monitored using a laser scanning confocal microscope (FV1200; Olympus Corporation, Tokyo, Japan). The strength of each fluorescent signal in 400 cells was examined and judged as positive if there was greater than 30% of the ATP signal.

Intracellular Ca²⁺ of THP-1 cells treated with the free radical inducer AAPH²³ was measured by Fluo-3 (F-23915; Molecular Probes, Eugene, OR, USA). Briefly, THP-1 cells were pre-incubated with 2 µM Fluo 3-AM in HBSS containing 0.02% pluronic F-127 for 30 min at 37°C, resuspended in RPMI1640 (with 10% FBS) containing 2.5 mM probenecid, seeded in 24-well plates, and then treated with AAPH in the presence or absence of H₂. Changes in Fluo-3 fluorescence signals were observed using a laser scanning confocal microscope (FV1200; Olympus).

Mass spectrometric analysis and presentation of data using heat maps. OxPAPC (dissolved in chloroform at 2.5 mg/mL) was analyzed using by electrospray ionization-mass spectrometry (ESI-MS) by using an LTQ ORBITRAP XL mass spectrometer (Thermo Fisher Scientific, San Jose, CA, USA) equipped with a nitrogen sheath gas flow rate of 40 AU at 300°C. The sample was directly infused. The scanning range was from m/z 250 to 1000 in the positive ion detection mode. The ion spray voltage was set to 4 kV. OxPAPC species were identified according to their m/z values and confirmed using mass spectrometric analysis as described previously.⁴⁴,⁴⁵

Two independent experiments were performed. The average of the data was used for construction of a heat map and displayed in mass spectrometric profiles. In the heat map, bands were arranged according to molecular mass from small to large, and the strength of each band obtained from H₂OxPAPC was compared with those by OxPAPC. Red and green bands represented increased and decreased levels as compared with those of OxPAPC, respectively. The mass spectrometric display indicates the average band from two experiments. Only when bands were detected by all of 10 experiments (two experiments at 0%, 0.2%, 0.3%, 1.3% and 5% of H₂), they were adopted.

Comprehensive analysis of gene expression. THP-1 cells were exposed for 4 h to PAPC or OxPAPC, H₂[1.3%]OxPAPC, and H₂[5%]OxPAPC that had been autoxidized for 3 days with 0%, 1.3%, or 5% H₂, respectively. Total RNA was extracted using a RNeasy Mini Kit according to the manufacturer’s protocol (Qiagen, Valencia, CA, USA) and labeled using a Low-Input QuickAmp Labeling Kit, One-Color (Agilent Technologies, Santa Clara, CA, USA). Gene expression analysis was performed on samples from three independent experiments using a microarray (SurePrint G3 Human GE 8 x 60 K v2 Microarray; Agilent Technologies). The raw microarray data were deposited in the Gene Expression Omnibus (GEO; accession number, GSE62434; http://www.ncbi.nlm.nih.gov/geo/query/acc.cgi?acc=GSE62434). CREB target genes were selected according to the CREB Target Gene Database (http://natural.salk.edu/CREB/), while NFAT target genes were selected by reference to Medline, as listed in Supplementary Table 1. Signal transduction pathways associated with each gene were identified according to the KEGG Pathway Database (http://www.genome.jp/kegg/pathway.html).

Quantitative real-time PCR. To quantify mRNA levels, quantitative real-time PCR was carried out using TaqMan Probe and Premix Ex Taq (Probe qPCR; TaKaRa Bio Inc., Shiga, Japan) in a TaKaRa PCR Thermal Cycler Dice TP960 (TaKaRa Bio) according to the manufacturer’s protocols. Primers and probes used for RT-PCR are described in Table 2.

ELISA (Enzyme-linked immuno-sorbent assay) HAEC and THP-1 cells were treated with PAPC, OxPAPC or H₂OxPAPC for 22 h. The IL-8 (HAEC) and TNF-α (THP-1) contents in the culture media were determined using Human CXCL8/IL-8 Quantikine ELISA Kit (R&D Systems, Minneapolis, MN, USA) and Human TNF-α Quantikine ELISA Kit (R&D Systems, Minneapolis, MN, USA), respectively, according to the manufacturer’s protocol.

Detection of lipid peroxidation in cultured cells. THP-1 cells (1 x 10⁵ cells/mL) were stained with 5 µM Liperfluor²⁵ for 30 min and then treated with 10 mM of AAPH²³ for 4.5 h in the absence or presence of the indicated concentrations of H₂ gas in a closed vessel. The cells were analyzed using a Cell Lab Quanta flow cytometer (Beckman Coulter, Miami, FL, USA).

Detection of the translocation of NFAT into the nucleus by immunofluorescence. THP-1 cells (1 x 10⁵ cells/mL) were treated with OxPAPC (0.1 mg/mL), or H₂[2.5%]OxPAPC (0.1 mg/mL) for 1.5 h, which were used for the Ca²⁺ signaling assay, and then the translocation of NFAT was determined using immunofluorescence as follows. The cells were fixed for 20 min with 10% neutral buffered formalin (3.8% formaldehyde), and then permeabilized with 0.2% Triton X-100 in Tris-buffered saline (TBS-T) for 10 min. After the cells were washed, and blocked with 5% nonfat milk in TBS-T, they were incubated with anti-NFAT1 antibodies (1:100 dilution; 25A10.D6.D2; Abcam, Cambridge, MA, USA) overnight at 4°C, followed by incubation with Alexa Fluor 488-conjugated anti-mouse antibodies (1:400 dilution; A-11029; Life Technologies, Carlsbad, CA, USA) for 1 h at 25°C. The cells were counterstained with Hoechst 33342. Immunofluorescence was observed using a laser scanning confocal microscope (FV1200; Olympus).
THP-1 cells (1 × 10^5 cells/mL) were treated with 10 mM AAPH for 3 h in the absence or presence of indicated concentrations of H2, and the NFAT translocation was investigated using immunofluorescence as described above.

**Cell culture.** THP-1 cells (ATCC) were cultured in RPMI1640 containing 10% FBS. Human aortic endothelial cells (HAEC) were obtained from Lonza and maintained in endothelial cell growth medium [EBM medium + growth supplements + FCS (Lonza)]. Cells were cultured at 37°C in a 5% CO2 humidified atmosphere and were used for experiments from passage 4 to 8.

**Statistical analysis.** Statistical differences between groups were assessed by one-way analysis of variance (ANOVA) with Tukey-Kramer post hoc analysis unless otherwise mentioned. Statistical analyses were performed with IBM SPSS21 software. Results were considered significant at P < 0.05. When 0.01 < P < 0.05, the actual P values were noted. Data are presented as means ± standard deviations.

Acknowledgements
We thank Ms. Mayumi Takeda and Ms. Suga Kato for technical assistance and secretarial work, respectively. Financial support for this study was provided by Grants-in-Aid for Scientific Research from the Japan Society for the Promotion of Science (23300257, 24651055, and 26282198 to S.O.; 23500971 and 26350129 to N.K.; and 25350907 to K.N.).

Author Contributions
S.O. conceived of and directed the project, analyzed data, and wrote the manuscript. N.K. planned each experiment. K.I., A.I., N.K., T.Y., and H.I. performed experiments on cell culture (by K.I.), Ca\(^{2+}\) signaling (by A.I.), gene expression (by N.K.), and chemical reactions (by K.N.), supported by H.I. and T.Y.

Additional Information
Supplementary information accompanies this paper at http://www.nature.com/srep

Competing financial interests: S.O. holds the right of a patent regarding a medical use of hydrogen gas.
