Abstract: We consider the high energy limit of the colour ordered one-loop five-gluon amplitude in the planar maximally supersymmetric $\mathcal{N} = 4$ Yang-Mills theory in the multi-Regge kinematics where all of the gluons are strongly ordered in rapidity. We apply the calculation of the one-loop pentagon in $D = 6 - 2\epsilon$ performed in a companion paper [1] to compute the one-loop five-gluon amplitude through to $O(\epsilon^2)$. Using the factorisation properties of the amplitude in the high-energy limit, we extract the one-loop gluon-production vertex to the same accuracy, and, by exploiting the iterative structure of the gluon-production vertex implied by the BDS ansatz, we perform the first computation of the two-loop gluon-production vertex up to and including finite terms.

Keywords: QCD, SYM, small $x$. 
1. Introduction

The colour-stripped one-loop five-gluon MHV amplitude in the planar maximally supersymmetric $\mathcal{N} = 4$ Yang-Mills theory to all orders in $\epsilon$ is given by \[2, 3\],

$$m_5^{(1)}(1, 2, 3, 4, 5) = -\frac{1}{4} \sum_{\text{cyclic}} s_{12}s_{23}I_4^m(1, 2, 3, 45, \epsilon) - \frac{\epsilon}{2} \epsilon_{1234}I_5^{6-2\epsilon}(\epsilon) ,$$  

where $m_5^{(1)}$ denotes the one-loop coefficient, i.e., the one-loop amplitude rescaled by the tree-level amplitude, and where the cyclicity is over $i = 1, \ldots, 5$. Here $I_4^m(1, 2, 3, 45, \epsilon)$ represents the one-mass box integral with an off-shell leg of virtuality $s_{45}$, $I_5^{6-2\epsilon}(\epsilon)$ is the (massless) one-loop pentagon integral evaluated in $6-2\epsilon$ dimensions, and the contracted Levi-Civita tensor is $\epsilon_{1234} = \text{tr}[\gamma_5 k_1 k_2 k_3 k_4]$. In a companion paper \[1\], we have performed the first analytic computation of the higher dimension pentagon, $I_5^{6-2\epsilon}(\epsilon)$, albeit in the simplified kinematical set-up of the multi-Regge kinematics \[4\]. In this limit, we have derived $I_5^{6-2\epsilon}(\epsilon)$ as an all-order expression in $\epsilon$, and explicitly expanded it through to $\mathcal{O}(\epsilon^2)$.

In the high-energy limit (HEL) $s \gg |t|$, any scattering process is dominated by the exchange of the highest-spin particle in the crossed channel. Thus, in perturbative QCD the leading contribution in powers of $s/t$ to any scattering process comes from gluon exchange in the $t$ channel. In this limit, scattering amplitudes undergo a Regge factorisation \[4, 5\] which allows an amplitude for gluon exchange to be decomposed in terms of building blocks associated with the various components of the amplitude. In the simplest case of four-gluon scattering, one exchanges a reggeised gluon (representing a gluon ladder) that is emitted from one scattering vertex and absorbed at the other. This emission is described by the coefficient function or impact factor. For processes involving more gluons, additional gluons are emitted by the gluon ladder and this emission is controlled by the gluon-production (or Lipatov) vertex. Using the high-energy factorisation for colour-stripped amplitudes \[6, 7\], we can relate the one-loop gluon-production vertex in the $\mathcal{N} = 4$ super Yang-Mills theory to the one-loop five-gluon amplitude given in Eq. (1.1) and extract it through to $\mathcal{O}(\epsilon^2)$.

Recently, Bern, Dixon and Smirnov (BDS) have proposed an iterative ansatz \[8, 9\] for the $l$-loop $n$-gluon scattering amplitude in the maximally supersymmetric $\mathcal{N} = 4$ Yang-Mills theory (MSYM), with the maximally-helicity violating (MHV) configuration and for arbitrary $l$ and $n$. The iterative structure of the BDS ansatz has been shown to be correct for the two-loop five-point amplitude through direct numerical calculation \[3\]. Together with the high-energy factorisation, that implies an iterative structure of the gluon-production vertex \[7\]. Thus, the knowledge of the one-loop gluon-production vertex through to $\mathcal{O}(\epsilon^2)$, allows us to perform the first computation of the two-loop gluon-production vertex up to and including the finite terms.

Our paper is organised as follows. In Section 2 we consider the five-point amplitude in the multi-Regge kinematics. First we make a precise definition of the multi-Regge kinematics and review how the tree-level MHV amplitude factorises in the high energy limit. The factorisation properties of the five-gluon amplitude are described in Section 2.2 and the relationship between the one-loop amplitude and the one-loop Lipatov vertex established.
We remind the reader of the iterative structure of the Lipatov vertex in Section 2.3 while its analytic continuation properties are discussed in Section 2.4. In Section 3 we present the one-loop five-point amplitude through to $O(\epsilon^2)$ and use it to compute the one-loop gluon-production vertex through to $O(\epsilon^2)$ in Section 4 where we find contributions from both the parity-even and parity-odd parts. In Section 5 we compute the two-loop gluon-production vertex through to finite terms. Our findings are briefly summarised in Section 6. Some of the technical details are enclosed in the Appendices. Further details on the multiparton light-cone momenta and how they behave in the multi-Regge kinematics are given in Appendices A and B, while the soft limit of the one-loop Lipatov vertex is further discussed in Appendix C.

2. Five-point amplitudes in multi-Regge kinematics

We consider a five-point amplitude, $g_1 g_2 \rightarrow g_3 g_4 g_5$, with all the momenta taken as outgoing, and label the legs cyclically clockwise. In the multi-Regge kinematics [4], the produced particles are strongly ordered in rapidity and have comparable transverse momenta,

$$y_3 \gg y_4 \gg y_5; \quad |p_{3\perp}| \simeq |p_{4\perp}| \simeq |p_{5\perp}|.$$ (2.1)

Accordingly, the Mandelstam invariants can be written in the approximate form (B.3)*. We label the momenta transferred in the $t$-channel as $q_1 = p_1 + p_5$, $q_2 = -p_2 - p_3$,

$$t_i = q_i^2. \quad \text{Then it is easy to see that in the multi-Regge kinematics the transverse components of the momenta $q_i$ dominate over the longitudinal components, $q_i^2 \simeq -|q_i\perp|^2$. In addition, } t_1 = s_{15} \text{ and } t_2 = s_{23} \text{, and we label } s = s_{12}, \text{ and } s_1 = s_{45},\ s_2 = s_{34}. \text{ Thus, the multi-Regge kinematics (2.1) become}

$$s \gg s_1,\ s_2 \gg -t_1,\ -t_2.$$ (2.3)

Labelling the transverse momentum of the particle emitted along the ladder as $\kappa = |p_{4\perp}|^2$, we can write

$$\kappa = \frac{s_1 s_2}{s},$$ (2.4)

which is known as the mass-shell condition (B.4).

2.1 Tree amplitudes in multi-Regge kinematics

The colour decomposition of the tree-level five-point amplitude is [10]

$$\mathcal{M}_5^{(0)}(1, 2, 3, 4, 5) = 2^{5/2} \sum_{S_5/Z_5} \text{tr}(T^{d_1} \cdots T^{d_5}) m_5^{(0)}(1, 2, 3, 4, 5),$$ (2.5)

where $d_i$ is the colour of a gluon of momentum $p_i$ and helicity $\nu_i$. The $T$‘s are the colour matrices† in the fundamental representation of SU($N$) and the sum is over the noncyclic

* A physically more intuitive representation of the invariants in terms of rapidities is given in Ref. [7].
† We use the normalization $\text{tr}(T^a T^d) = \delta^{ad}/2$, although it is immaterial in what follows.
permutations $S_5/Z_5$ of the set $[1, \ldots, 5]$. For five gluons, there are only MHV helicity configurations $(-,-,+,+,+)$ for which the tree-level gauge-invariant colour-stripped amplitudes assume the form

$$m^{(0)}_5(1, 2, 3, 4, 5) = g^3 \frac{\langle p_ip_j \rangle^4}{\langle p_1p_2 \rangle \langle p_2p_3 \rangle \langle p_3p_4 \rangle \langle p_4p_5 \rangle \langle p_5p_1 \rangle},$$

where $i$ and $j$ are the two gluons of negative helicity. The colour structure of Eq. (2.5) in multi-Regge kinematics is known [11, 12, 13] and will not be considered further. Here we concentrate on the behaviour of the colour-stripped amplitude (2.6). Using the spinor products in multi-Regge kinematics (B.5), the amplitude (2.6) takes the factorised form [12],

$$m^{(0)}_5(1, 2, \ldots, 5) = s \left[ gC^{(0)}(p_2, p_3) \right] \frac{1}{t_2} \left[ gV^{(0)}(q_2, q_1; \kappa) \right] \frac{1}{t_1} \left[ gC^{(0)}(p_1, p_5) \right]$$

which is shown schematically in Fig. 1.

The gluon coefficient functions $C^{(0)}$, which yield the LO gluon impact factors, are given in Ref. [4] in terms of their spin structure and in Ref. [12, 14] at fixed helicities of the external gluons,

$$C^{(0)}(p^-_2, p^+_3) = 1, \quad C^{(0)}(p^-_1, p^+_5) = \frac{p^\perp_5}{p^\perp_1},$$

with the complex transverse momentum $p^\perp = p_x + ip_y$. The vertex for the emission of a gluon along the ladder is [12, 15, 16]

$$V^{(0)}(q_2, q_1, \kappa) = \sqrt{2} \frac{q^\perp_2, q^\perp_1}{p^\perp_4},$$

with $p_4 = q_2 - q_1$.

### 2.2 High-energy factorisation of the five-point amplitude

The Regge factorisation of the tree-level colour-stripped amplitude is given by Eq. (2.7). In the leading logarithmic (LL) approximation, the virtual radiative corrections to Eq. (2.7) are obtained, to all orders in $\alpha_s$, by replacing the propagator of the $t$-channel gluon by its reggeised form [4]. That is, by making the replacement

$$\frac{1}{t_i} \rightarrow \frac{1}{t_i} \left( \frac{s_i}{\tau} \right)^{\alpha(t_i)},$$

Figure 1: Five-point amplitude in the multi-Regge kinematics. The green blobs indicate the coefficient functions (impact factors) and the vertex describing the emission of gluons along the ladder.
in Eq. (2.7), where $\alpha(t_i)$ can be written in dimensional regularization in $d = 4 - 2\epsilon$ dimensions as
\[
\alpha(t_i) = g^2 c_\Gamma \left( \frac{\mu^2}{-t_i} \right)^\epsilon N \frac{2}{\epsilon},
\]
with $N$ colours, and
\[
c_\Gamma = \frac{1}{(4\pi)^{2-\epsilon}} \frac{\Gamma(1+\epsilon)\Gamma^2(1-\epsilon)}{\Gamma(1-2\epsilon)}.
\]
\[
\alpha(t_i) \text{ is the Regge trajectory and accounts for the higher order corrections to gluon exchange in the } t_i \text{ channel.}
\]
In Eq. (2.10), the reggeisation scale $\tau$ is introduced to separate contributions to the reggeized propagator, the coefficient function and the gluon-production vertex. It is much smaller than any of the $s$-type invariants, and it is of the order of the $t$-type invariants. In order to go beyond the LL approximation and to compute the higher-order corrections to the gluon-production vertex (2.9), we need a high-energy prescription [5] which disentangles the virtual corrections to the gluon-production vertex from those to the coefficient functions (2.8) and from those that reggeize the gluon (2.10). The high-energy prescription of Ref. [5] is given at the colour-dressed amplitude level in QCD, where it holds to the next-to-leading-logarithmic (NLL) accuracy. In Ref. [6], we showed that the high-energy prescription, when applied to the colour-stripped four-point amplitude, is valid up to three loops. In Ref. [7], we conjectured the factorised form of a generic colour-stripped $n$-gluon amplitude in the multi-Regge kinematics. For the five-point amplitude, $g_1 g_2 \to g_3 g_4 g_5$, that prescription yields
\[
m_5 = s \left[ g C(p_2,p_3,\tau) \right] \frac{1}{t_2} \left( \frac{-s_2}{\tau} \right)^{\alpha(t_2)} \left[ g V(q_2,q_1,\kappa,\tau) \right] \frac{1}{t_1} \left( \frac{-s_1}{\tau} \right)^{\alpha(t_1)} \left[ g C(p_1,p_5,\tau) \right],
\]
with the invariants labelled as in Section 2, i.e. $t_1 = s_{51}$, $t_2 = s_{23}$, $s_1 = s_{45}$ and $s_2 = s_{34}$. In Eq. (2.13), we suppressed the dependence of the coefficient function and of the gluon-production vertex on the dimensional regularisation parameters $\mu^2$ and $\epsilon$. In order for the amplitude $m_5$ to be real, Eq. (2.13) is taken in the Euclidean region where all the invariants are negative,
\[
s, s_1, s_2, t_1, t_2, \kappa < 0.
\]
Thus, the multi-Regge kinematics (2.3) become,
\[
-s \gg -s_1, -s_2 \gg -t_1, -t_2.
\]
Then the mass-shell condition (2.4) for the intermediate gluon is
\[
-\kappa = \frac{(-s_1)(-s_2)}{-s},
\]
where $\kappa = -|p_{4\perp}|^2$.
In Eq. (2.13), the Regge trajectory has the perturbative expansion,
\[
\alpha(t_i) = \bar{g}^2 \tilde{\alpha}^{(1)}(t_i) + \bar{g}^4 \tilde{\alpha}^{(2)}(t_i) + \bar{g}^6 \tilde{\alpha}^{(3)}(t_i) + \mathcal{O}(\bar{g}^8),
\]
with \( i = 1, 2 \), and with the rescaled coupling
\[
\tilde{g}^2 = g^2 c_T N. \tag{2.18}
\]

In Eq. (2.13), the coefficient functions \( C \) and the gluon-production vertex \( V \) are also expanded in the rescaled coupling,
\[
C(p_i, p_j, \tau) = C^{(0)}(p_i, p_j) \left( 1 + \sum_{r=1}^{s-1} \tilde{g}^{2r} \tilde{C}^{(r)}(t_k, \tau) + \mathcal{O}(\tilde{g}^{2s}) \right), \tag{2.19}
\]
\[
V(q_2, q_1, \kappa, \tau) = V^{(0)}(q_2, q_1) \left( 1 + \sum_{r=1}^{s-1} \tilde{g}^{2r} \tilde{V}^{(r)}(t_1, t_2, \kappa, \tau) + \mathcal{O}(\tilde{g}^{2s}) \right). \tag{2.20}
\]

with \((p_i + p_j)^2 = t_k\) where \( C \) and \( V \) are real, up to overall complex phases in \( C^{(0)} \), Eq. (2.8), and \( V^{(0)} \), Eq. (2.9), induced by the complex-valued helicity bases. Note that because several transverse scales occur, we prefer to associate the renormalisation scale dependence of the trajectory, coefficient function and gluon-production vertex with the loop coefficients rather than in the rescaled coupling,
\[
\tilde{\alpha}^{(n)}(t_i) = \left( \frac{\mu^2}{-t_i} \right)^{n\epsilon} \alpha^{(n)}(t_i), \quad \tilde{C}^{(n)}(t_k, \tau) = \left( \frac{\mu^2}{-t_k} \right)^{n\epsilon} C^{(n)}(t_k, \tau), \tag{2.21}
\]
\[
\tilde{V}^{(n)}(t_1, t_2, \kappa, \tau) = \left( \frac{\mu^2}{-\kappa} \right)^{n\epsilon} V^{(n)}(t_1, t_2, \kappa, \tau). \tag{2.22}
\]

The perturbative expansion of Eq. (2.13) can be written as
\[
m_5 = m_5^{(0)} \left( 1 + \tilde{g}^2 m_5^{(1)} + \tilde{g}^4 m_5^{(2)} + \tilde{g}^6 m_5^{(3)} + \mathcal{O}(\tilde{g}^8) \right). \tag{2.23}
\]

In the expansion of Eq. (2.21), the knowledge of the \( l \)-loop five-point amplitude in the multi-Regge kinematics (2.15), together with the \( l \)-loop trajectory \( \alpha^{(l)} \) and coefficient function \( C^{(l)} \), allows one to derive the gluon-production vertex to the same accuracy. The one-loop coefficient is
\[
m_5^{(1)}(\epsilon) = \tilde{\alpha}^{(1)}(t_1)L_1 + \tilde{\alpha}^{(1)}(t_2)L_2 + C^{(1)}(t_1, \tau) + \tilde{C}^{(1)}(t_2, \tau) + \tilde{V}^{(1)}(t_1, t_2, \kappa, \tau) \tag{2.24}
\]
where \( L_i = \ln(-s_i/\tau) \) and \( i = 1, 2 \). The one-loop trajectory is [4],
\[
\alpha^{(1)} = \frac{2}{\epsilon}, \tag{2.25}
\]
and the one-loop coefficient function is [5, 17, 18, 19, 20, 21] to all orders in \( \epsilon \) given by
\[
C^{(1)}(t, \tau) = \frac{\psi(1 + \epsilon) - 2\psi(-\epsilon) + \psi(1)}{\epsilon} - \frac{1}{\epsilon} \ln \frac{-t}{\tau}. \tag{2.26}
\]

Since \( \alpha^{(1)} \) and \( C^{(1)}(t, \tau) \) are known to all orders in \( \epsilon \), we see that the order to which \( m_5^{(1)}(\epsilon) \) is known dictates the order to which one may extract \( V^{(n)}(t_1, t_2, \kappa, \tau) \).
Similarly the two-loop coefficient of the five-point amplitude is
\begin{equation}
    m_5^{(2)}(\epsilon) = \frac{1}{2} \left[ m_5^{(1)}(\epsilon) \right]^2 + \tilde{\alpha}^{(2)}(t_1)L_1 + \tilde{\alpha}^{(2)}(t_2)L_2
\end{equation}
\begin{equation}
    + \tilde{C}^{(2)}(t_1, \tau) + \tilde{V}^{(2)}(t_1, t_2, \kappa, \tau) + \tilde{C}^{(2)}(t_2, \tau)
\end{equation}
\begin{equation}
    - \frac{1}{2} \left( \tilde{C}^{(1)}(t_1, \tau) \right)^2 - \frac{1}{2} \left( \tilde{V}^{(1)}(t_1, t_2, \kappa, \tau) \right)^2 - \frac{1}{2} \left( \tilde{C}^{(1)}(t_2, \tau) \right)^2,
\end{equation}
where \( m_5^{(1)}(\epsilon), \tilde{C}^{(1)}(t, \tau) \) and \( \tilde{V}^{(1)}(t_1, t_2, \kappa, \tau) \) must be known through to \( \mathcal{O}(\epsilon^2) \). The two-loop trajectory, \( \alpha^{(2)} \), is known in full QCD \[22, 23, 24, 25, 26\]. In MSYM, it has been computed through \( \mathcal{O}(\epsilon^0) \) directly \[27\] and using the maximal transcendentality principle \[28\], and through \( \mathcal{O}(\epsilon^2) \) directly \[6\],
\begin{equation}
    \alpha^{(2)} = -\frac{2\zeta_2}{\epsilon} - 2\zeta_3 - 8\zeta_4 \epsilon + (36\zeta_2\zeta_3 + 82\zeta_5) \epsilon^2 + \mathcal{O}(\epsilon^3). \tag{2.26}
\end{equation}

The MSYM two-loop coefficient function has been computed through \( \mathcal{O}(\epsilon^2) \) \[6\],
\begin{equation}
    C^{(2)}(t, \tau) = \frac{2}{\epsilon^4} + \frac{2}{\epsilon^3} \ln \frac{-t}{\tau} - \left( 5\zeta_2 - \frac{1}{2} \ln^2 \frac{-t}{\tau} \right) \frac{1}{\epsilon^2} - \left( \zeta_3 + 2\zeta_2 \ln \frac{-t}{\tau} \right) \frac{1}{\epsilon}
\end{equation}
\begin{equation}
    - \frac{55}{4} \zeta_4 + \left( \zeta_2 \zeta_3 - 41\zeta_5 + \zeta_4 \ln \frac{-t}{\tau} \right) \epsilon
\end{equation}
\begin{equation}
    - \left( \frac{95}{2} \zeta_3^2 + \frac{1695}{8} \zeta_6 + (18\zeta_2\zeta_3 + 42\zeta_5) \ln \frac{-t}{\tau} \right) \epsilon^2 + \mathcal{O}(\epsilon^3) \tag{2.27}
\end{equation}
\begin{equation}
    = \frac{1}{2} \left[ C^{(1)}(t, \tau) \right]^2 + \frac{\zeta_2}{\epsilon^2} + \left( \zeta_3 + 2\zeta_2 \ln \frac{-t}{\tau} \right) \frac{1}{\epsilon}
\end{equation}
\begin{equation}
    + \left( \zeta_3 \ln \frac{-t}{\tau} - 19\zeta_4 \right) + \left( 4\zeta_4 \ln \frac{-t}{\tau} - 2\zeta_2\zeta_3 - 39\zeta_5 \right) \epsilon
\end{equation}
\begin{equation}
    - \left( 48\zeta_3^2 + \frac{1773}{8} \zeta_6 + (18\zeta_2\zeta_3 + 41\zeta_5) \ln \frac{-t}{\tau} \right) \epsilon^2 + \mathcal{O}(\epsilon^3).
\end{equation}

Armed with this knowledge together with the two-loop amplitude, \( m_5^{(2)}(\epsilon) \), one could extract the two-loop Lipatov vertex. However, as we showed in Ref. \[7\], the Lipatov vertex satisfies its own iterative formula, and one can avoid needing to know \( m_5^{(2)}(\epsilon) \).

### 2.3 The two-loop five-point amplitude and the BDS ansatz

In the normalization of Refs. \[6, 7\], the iterative structure of the two-loop five-point amplitude in the \( \mathcal{N} = 4 \) super Yang-Mills theory is given by \[8, 9\]
\begin{equation}
    m_5^{(2)}(\epsilon) = \frac{1}{2} \left[ m_5^{(1)}(\epsilon) \right]^2 + \frac{2G^2(\epsilon)}{G(2\epsilon)} f^{(2)}(\epsilon) m_5^{(1)}(2\epsilon) + 4Const^{(2)} + \mathcal{O}(\epsilon), \tag{2.28}
\end{equation}
where \( Const^{(2)} = -\zeta_2^2/2 \), the \( f^{(2)} \) function is
\begin{equation}
    f^{(2)}(\epsilon) = -\zeta_2 - \zeta_3 \epsilon - \zeta_4 \epsilon^2, \tag{2.29}
\end{equation}
and
\begin{equation}
    G(\epsilon) = \frac{e^{-\gamma \epsilon} \Gamma(1-2\epsilon)}{\Gamma(1+\epsilon)\Gamma^2(1-\epsilon)} = 1 + \mathcal{O}(\epsilon^2), \tag{2.30}
\end{equation}
and where the one-loop five-point amplitude, \( m_5^{(1)}(\epsilon) \), must be known through to \( \mathcal{O}(\epsilon^2) \). In Ref. [3], the two-loop five-point amplitude has been shown to fulfil the BDS ansatz by the numeric calculation of \( m_5^{(1)}(\epsilon) \) through to \( \mathcal{O}(\epsilon^2) \) and of \( m_5^{(2)}(\epsilon) \) through to finite terms.

In Ref. [6], the iterative structure [8, 9] and the Regge factorisation of the two-loop four-point amplitude have been used to write the two-loop Regge trajectory and coefficient function through to finite terms in terms of the constant \( \text{Const}^{(2)} \), the function \( f^{(2)}(\epsilon) \), and of the one-loop coefficient function \( C^{(1)}(\epsilon) \),

\[
\alpha^{(2)}(\epsilon) = 2 f^{(2)}(\epsilon) \alpha^{(1)}(2\epsilon) + \mathcal{O}(\epsilon), \\
C^{(2)}(\epsilon) = \frac{1}{2} \left[ C^{(1)}(\epsilon) \right]^2 + \frac{2G^2(\epsilon)}{G(2\epsilon)} f^{(2)}(\epsilon) C^{(1)}(2\epsilon) + 2 \text{Const}^{(2)} + \mathcal{O}(\epsilon),
\]

(2.31)

where the one-loop coefficient function \( C^{(1)}(\epsilon) \) is needed through to \( \mathcal{O}(\epsilon^2) \), and where we stress only the dependence on the dimensional-regularisation parameter \( \epsilon \).

Combining Eq. (2.31), the iterative structure of the two-loop five-point amplitude (2.28), and the constant term of the high-energy expansion (2.25), one can find an iteration formula for the two-loop gluon-production vertex [7],

\[
V^{(2)}(\epsilon) = \frac{1}{2} \left[ V^{(1)}(\epsilon) \right]^2 + \frac{2G^2(\epsilon)}{G(2\epsilon)} f^{(2)}(\epsilon) V^{(1)}(2\epsilon) + \mathcal{O}(\epsilon),
\]

(2.32)

where the one-loop gluon-production vertex must be known through to \( \mathcal{O}(\epsilon^2) \). Note that in order to compute the two-loop gluon-production vertex through to finite terms, it is not needed to know the two-loop five-point amplitude or the two-loop coefficient function explicitly. It suffices to know the one-loop five-point amplitude through to \( \mathcal{O}(\epsilon^2) \), from which one can derive the one-loop gluon-production vertex to the same accuracy.

### 2.4 Analytic continuation of the five-point amplitude to the physical region

We analytically continue the high-energy prescription for the colour-stripped amplitude (2.13) to the physical region, where \( s, s_1, s_2 \) are positive and \( t_1, t_2 \) are negative,

\[
(-s) \rightarrow e^{-i\pi} s, \quad (-s_1) \rightarrow e^{-i\pi} s_1, \quad (-s_2) \rightarrow e^{-i\pi} s_2,
\]

(2.33)

and where the multi-Regge kinematics are

\[
s \gg s_1, \quad s_2 \gg -t_1, \quad -t_2.
\]

(2.34)

Eq. (2.33) implies that Eqs. (2.22) and (2.25) are continued by \( \ln(-s_j) = \ln(s_j) - i\pi \), for \( s_j > 0 \) and \( j = 1, 2 \). The mass-shell condition (2.16) and the analytic continuation (2.33) imply that the transverse scale \( \kappa \) is continued as,

\[
(-\kappa) \rightarrow e^{-i\pi} \kappa,
\]

(2.35)

and the mass-shell condition is reduced to the usual one in the physical region, Eq. (2.4). Note that the expansions of Eqs. (2.17)–(2.20) are still valid, but because of the analytic
continuation on $\kappa$, which implies that $\ln(-\kappa) = \ln(\kappa) - i\pi$, for $\kappa > 0$, the gluon-production vertex becomes complex,

$$
\bar{V}^{(n)}(t_1, t_2, \kappa, \tau) = \left( \frac{\mu^2}{\kappa} \right)^{ne} V^{(n)}_{\text{phys}}(t_1, t_2, \kappa, \tau),
$$

(2.36)

with

$$
V^{(n)}_{\text{phys}}(t_1, t_2, \kappa, \tau) = e^{i\pi n\kappa} V^{(n)}(t_1, t_2, e^{-i\pi}(-\kappa), \tau).
$$

(2.37)

3. The one-loop five-point amplitude

We may write the one-loop five-point amplitude (1.1) for general kinematics as,

$$
m_5^{(1)}(1, 2, 3, 4, 5) = m_{5e}^{(1)}(1, 2, 3, 4, 5) + m_{5o}^{(1)}(1, 2, 3, 4, 5),
$$

(3.1)

where the parity-even and odd contributions are given to all orders in $\epsilon$ by [2, 3],

$$
m_{5e}^{(1)}(1, 2, 3, 4, 5) = -\frac{1}{4} 2G(\epsilon) \sum_{\text{cyclic}} s_{12}s_{23} I_4^{1m}(1, 2, 3, 4, 5, \epsilon),
$$

(3.2)

$$
m_{5o}^{(1)}(1, 2, 3, 4, 5) = -\frac{\epsilon}{2} 2G(\epsilon) \epsilon_{1234} I_5^{6-2\epsilon}(\epsilon),
$$

(3.3)

where the cyclicity is over $i = 1, \ldots, 5$. Here $I_4^{1m}(1, 2, 3, 4, 5, \epsilon)$ is the one-mass box with the massive leg of virtuality $s_{45}$, $I_5^{6-2\epsilon}(\epsilon)$ is the pentagon evaluated in $6 - 2\epsilon$ dimensions, the contracted Levi-Civita tensor is $\epsilon_{1234} = \text{tr}[^{\gamma}k_1 k_2 k_3 k_4]$, and we use the normalization of Refs. [6, 7], with $G(\epsilon)$ as in Eq. (2.30).

For multi-Regge kinematics (2.15) in the Euclidean region (2.14), the parity-even contribution is, to all orders in $\epsilon$,

$$
m_{5e}^{(1)}(1, 2, 3, 4, 5)
= -\frac{1}{\epsilon^2} \left( \frac{\mu^2}{-\kappa} \right)^{\epsilon} \Gamma(1 + \epsilon)\Gamma(1 - \epsilon)
+ \frac{2}{\epsilon} \left( \frac{\mu^2}{-t_1} \right)^{\epsilon} (\psi(1) - \psi(-\epsilon)) + \frac{1}{\epsilon} \left( \frac{\mu^2}{-t_2} \right)^{\epsilon} (2\psi(1) - 3\psi(-\epsilon) + \psi(1 + \epsilon))
+ \frac{1}{\epsilon^2} \left( \frac{\mu^2}{-t_1} \right)^{\epsilon} \ln s_1 + \frac{1}{\epsilon} \left( \frac{\mu^2}{-t_2} \right)^{\epsilon} \ln s_2
+ \frac{1}{\epsilon} \left( \frac{\mu^2}{-t_1} \right)^{\epsilon} \ln \frac{s_1}{\kappa} + \frac{1}{\epsilon} \left( \frac{\mu^2}{-t_2} \right)^{\epsilon} \ln \frac{s_2}{\kappa}
+ \frac{1}{\epsilon} \left( \frac{\mu^2}{-t_1} \right)^{\epsilon} \ln \frac{s_1}{t_2 - t_1} + \frac{1}{\epsilon} \left( \frac{\mu^2}{-t_2} \right)^{\epsilon} \ln \frac{s_2}{t_2 - t_1},
$$

(3.4)
for \((-t_2) > (-t_1)\), and

\[
2F_1(-\epsilon, 1, 1 - \epsilon; z) = 1 - \sum_{n=1}^{\infty} \text{Li}_n(z) \epsilon^n,
\]

\[
2F_1(1, 1 + \epsilon, 2 + \epsilon; z) = \frac{\text{Li}_1(z)}{z} + \left(\frac{\text{Li}_1(z)}{z} - \frac{\text{Li}_2(z)}{z}\right) \epsilon + \left(\frac{\text{Li}_3(z)}{z} - \frac{\text{Li}_2(z)}{z}\right) \epsilon^2
\]

\[
+ \left(\frac{\text{Li}_3(z)}{z} - \frac{\text{Li}_4(z)}{z}\right) \epsilon^3 + \left(\frac{\text{Li}_5(z)}{z} - \frac{\text{Li}_4(z)}{z}\right) \epsilon^4 + \ldots
\]

(3.5)

where \(\text{Li}_1(z) = -\ln(1 - z)\). The parity-even term for \((-t_1) > (-t_2)\) is obtained by exchanging \(t_1\) and \(t_2\) in Eq. (3.4). Eq. (3.4) is manifestly real; it is also symmetric in \(t_1\) and \(t_2\), although not manifestly. It can be put in a manifestly symmetric form, at the price of introducing imaginary parts, which cancel only after combining all the terms. Eq. (3.4) agrees through to \(O(\epsilon^0)\) with the \(N = 4\) part of the one-loop five-gluon amplitude in QCD [29] in the multi-Regge kinematics [18].

The parity-odd contribution is characterised by the contracted Levi-Civita tensor which can be written as,

\[
\epsilon_{1234} = s_{12}s_{34} - s_{13}s_{24} + s_{14}s_{23} - 2(12)[23](34)[41].
\]

(3.6)

In the multi-Regge kinematics (2.15) this becomes

\[
\epsilon_{1234} = (-s)(p_{3\perp}p_{4\perp}^* - p_{4\perp}p_{3\perp}^*).
\]

(3.7)

Therefore we see that in the high energy limit, the parity-odd contribution (3.3) is given by

\[
m_{50}^{(1)}(1, 2, 3, 4, 5) = -\epsilon G(\epsilon)(-s)(p_{3\perp}p_{4\perp}^* - p_{4\perp}p_{3\perp}^*)(\frac{p_{\perp}^2}{-\kappa})^\epsilon \mathcal{P},
\]

(3.8)

where the function \(\mathcal{P}\) is

\[
\mathcal{P} = \begin{cases} 
\frac{1}{st_2} T^{(IIa)}(\kappa, t_1, t_2) & \text{for } -\sqrt{s_{t_1}} s_{t_2} + \sqrt{s_{t_2}} s_{t_1} > 1 \text{ and } -t_1 < -t_2, \\
\frac{1}{s_{1s_2}} T^{(I)}(\kappa, t_1, t_2) & \text{for } \sqrt{s_{t_1}} s_{t_2} + \sqrt{s_{t_2}} s_{t_1} < 1.
\end{cases}
\]

(3.9)
To all orders in $\epsilon$, $\mathcal{I}^{(Ia)}(\kappa, t_1, t_2)$ is [1],

$$
\mathcal{I}^{(Ia)}(\kappa, t_1, t_2)
= -\frac{1}{\epsilon^3} y_2^{-\epsilon} \Gamma(1 - 2\epsilon) \Gamma(1 + \epsilon)^2 F_4 \left( 1 - 2\epsilon, 1 - \epsilon, 1 - \epsilon, 1 - \epsilon; -y_1, y_2 \right)
+ \frac{1}{\epsilon^3} \Gamma(1 + \epsilon) \Gamma(1 - \epsilon) F_4 \left( 1, 1 - \epsilon, 1 - \epsilon, 1 + \epsilon; -y_1, y_2 \right)
- \frac{1}{\epsilon^2} y_1 \gamma y_2^{-\epsilon} \left\{ \ln y_1 + \psi(1 - \epsilon) - \psi(-\epsilon) \right\} F_4 \left( 1, 1 - \epsilon, 1 + \epsilon, 1 - \epsilon; -y_1, y_2 \right)
+ \frac{\partial}{\partial \delta} F_{0,2}^{2,1} \left( \begin{array}{c} 1 + \delta + 1 - \epsilon \\ 1 + \delta + 1 - \epsilon + \epsilon + \delta \end{array} \right)_{|\delta=0} \left( \begin{array}{c} 1 - - \\ 1 - - \end{array} \right) - y_1, y_2 \right) \right\} \left( \begin{array}{c} \ln y_1 + \psi(1 + \epsilon) - \psi(-\epsilon) \right\} F_4 \left( 1, 1 + \epsilon, 1 + \epsilon, 1 + \epsilon; -y_1, y_2 \right)
+ \frac{\partial}{\partial \delta} F_{0,2}^{2,1} \left( \begin{array}{c} 1 + \delta + 1 + \epsilon + \epsilon + \delta \end{array} \right)_{|\delta=0} \left( \begin{array}{c} 1 - - \\ 1 - - \end{array} \right) - y_1, y_2 \right) \right\},
$$

(3.10)

with

$$
y_1 = \frac{\kappa}{t_2} \quad \text{and} \quad y_2 = \frac{t_1}{t_2},
$$

(3.11)

and where we introduced the Appell function

$$
F_4(a, b, c, d; x, y) = \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} \frac{(a)_{m+n} (b)_{m+n} (c)_m (d)_n}{m! n!} x^m y^n,
$$

(3.12)

and the Kampé de Fériet function

$$
F_{p', q'}^{p, q} \left( \begin{array}{c|c} \alpha_i & \beta_j \gamma_j \\ \alpha_i' & \beta_j' \gamma_j' \end{array} \right) x, y = \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} \frac{\prod_{i=1}^{p} (\alpha_i)_{m+n} \prod_{j=1}^{q} (\beta_j)_{m} (\gamma_j)_{n}}{\prod_{i=1}^{p'} (\alpha_i')_{m+n} \prod_{j=1}^{q'} (\beta_j')_{m} (\gamma_j')_{n}} \frac{x^m y^n}{m! n!},
$$

(3.13)

with $1 \leq i \leq p$, $1 \leq j \leq q$, $1 \leq k \leq p'$ and $1 \leq \ell \leq q'$. In Ref. [1], $\mathcal{I}^{(Ia)}(\kappa, t_1, t_2)$ is given as a Laurent expansion through to $O(\epsilon)$ in terms of Goncharov’s multiple polylogarithms.

A few comments are in order: Eq. (3.8) starts at $O(\epsilon)$, because Eq. (3.10) is finite: all the poles in $\epsilon$ cancel. Furthermore, because of the contracted Levi-Civita tensor (3.6) in Eq. (1.1), new momentum structures, other than the ones of Eqs. (2.8) and (2.9), occur in $m_5^{(5)}$.

In the region where $\sqrt{\frac{s_1}{s_{12}}} - \sqrt{\frac{s_2}{s_{12}}} > 1$ and $-t_1 > -t_2$, which we term $IIb$, $\mathcal{I}^{(Ib)}$ is given by [1],

$$
\mathcal{I}^{(Ib)}(\kappa, t_1, t_2) = \frac{t_2}{t_1} \mathcal{I}^{(Ia)}(\kappa, t_2, t_1)
$$

(3.14)

In Eq. (3.9), $\mathcal{I}^{(I)}(\kappa, t_1, t_2)$ can be derived from $\mathcal{I}^{(Ia)}(\kappa, t_1, t_2)$ by means of an analytic continuation, as detailed in Ref. [1], where it is also given explicitly to all orders in $\epsilon$, as well as a Laurent expansion through to $O(\epsilon)$ in terms of Goncharov’s multiple polylogarithms.
3.1 Soft limit

As discussed in Ref. [1], the limit in which the intermediate gluon becomes soft, \( p_4 \rightarrow 0 \), and thus \( \kappa \rightarrow 0 \), \( t_1 \rightarrow t \) and \( t_2 \rightarrow t \), is realised in the regions \( IIa \) and \( IIb \) of Eq. (3.9). Thus,

\[
\lim_{p_4 \to 0} m_{5e}^{(1)}(1, 2, 3, 4, 5) = \epsilon G(\epsilon) \frac{P_{3\perp}P_{4\perp} - P_{4\perp}P_{3\perp}}{t} \mathcal{I}^{(II)}(\kappa, t). \tag{3.15}
\]

\( \mathcal{I}^{(II)}(\kappa, t) \) is obtained from Eq. (3.10) by taking the limits \( t_1 \rightarrow t \) and \( t_2 \rightarrow t \). Because \( \mathcal{I}^{(II)}(\kappa, t) \) is logarithmic in \( \kappa/t \), the parity-odd contribution is power suppressed and thus vanishes as \( p_4 \rightarrow 0 \). Therefore the soft limit of the full one-loop five-point amplitude is given solely by the soft limit of the parity-even contribution,

\[
\lim_{p_4 \to 0} m_{5e}^{(1)}(1, 2, 3, 4, 5) = \frac{2}{\epsilon} \left( \frac{\mu^2}{\epsilon t} \right) \left( \psi(1 + \epsilon) - 2\psi(-\epsilon) + \psi(1) + \ln \frac{s}{t} \right) - \frac{1}{\epsilon^2} \left( \frac{\mu^2}{-\kappa} \right) \frac{\pi \epsilon}{\sin(\pi \epsilon)}. \tag{3.16}
\]

Using Eq. (C.7), we see that Eq. (3.16) fulfills the soft limit of the one-loop five-point amplitude in the multi-Regge kinematics (C.4).

4. The one-loop gluon-production vertex

In order to compute the one-loop gluon-production vertex, we use Eq. (2.19) and subtract the one-loop trajectory (2.23) and coefficient function (2.24) from the one-loop five-point amplitude (2.22) and (3.4). Thus, we obtain the gluon-production vertex,

\[
\bar{V}^{(1)}(t_1, t_2, \tau, \kappa) = \bar{V}^{(1)}_e(t_1, t_2, \tau, \kappa) + \bar{V}^{(1)}_o(t_1, t_2, \kappa), \tag{4.1}
\]

in terms of parity-even and odd contributions,

\[
\bar{V}^{(1)}_e(t_1, t_2, \tau, \kappa) = m_{5e}^{(1)}(1, 2, 3, 4, 5) - \bar{a}^{(1)}(t_1)L_1 - \bar{a}^{(1)}(t_2)L_2 - \bar{C}^{(1)}(t_1, \tau) - \bar{C}^{(1)}(t_2, \tau),
\]

\[
\bar{V}^{(1)}_o(t_1, t_2, \kappa) = m_{5o}^{(1)}(1, 2, 3, 4, 5). \tag{4.2}
\]

Because the high-energy coefficient functions and the Regge trajectory are parity-even, the parity-odd part of the one-loop gluon-production vertex equals the parity-odd part of the five-point amplitude (3.8), and accordingly does not depend on the factorisation scale \( \tau \). Using Eq. (2.20), in the unphysical region (2.14) the parity-even contribution is, to all orders in \( \epsilon \),

\[
V^{(1)}_e(t_1, t_2, \tau, \kappa) = -\frac{1}{\epsilon^2} \Gamma(1 + \epsilon) \Gamma(1 - \epsilon) \left( \frac{\kappa}{t_1} \right)^\epsilon \left( \frac{\psi(1) - \psi(1 + \epsilon)}{\epsilon} + \frac{1}{\epsilon} \ln \frac{-t_1}{\tau} \right) + \left( \frac{\kappa}{t_2} \right)^\epsilon \left( \frac{\psi(1) - \psi(-\epsilon)}{\epsilon} + \frac{1}{\epsilon} \ln \frac{-t_2}{\tau} \right) \tag{4.3}
\]

\[
+ \frac{1}{\epsilon^2} \left( \frac{\kappa}{t_1} \right)^\epsilon \left( \frac{\kappa}{t_2} \right)^\epsilon 2F_1 \left( \epsilon, 1, 1 - \epsilon; \frac{t_1}{t_2} \right) - \frac{1}{\epsilon(1 + \epsilon)} \left( \frac{\kappa}{t_2} \right)^\epsilon \frac{t_1}{t_2} 2F_1 \left( 1, 1 + \epsilon, 2 + \epsilon; \frac{t_1}{t_2} \right) \]

\[
- \frac{1}{\epsilon} \left[ \left( \frac{\kappa}{t_1} \right)^\epsilon + \left( \frac{\kappa}{t_2} \right)^\epsilon \right] \left[ \ln \frac{-\kappa}{\tau} + \ln \frac{t_1 - t_2}{\tau} \right].
\]
Using Eqs. (2.20) and (3.8), the parity-odd contribution is, to all orders in \( \epsilon \),

\[
V^{(1)}_{o}(t_1, t_2, \kappa) = -\epsilon G(\epsilon) (-s) \left( p_{3\perp} p_{4\perp}^* - p_{4\perp} p_{3\perp}^* \right) P,
\]

with \( P \) given by Eq. (3.9), which also cancels the apparent dependence on \( s \) above.

In the soft limit, \( \kappa \to 0 \), the parity-even part of the one-loop gluon-production vertex (4.3) agrees to all orders in \( \epsilon \) with the soft limit of the corresponding QCD vertex (C.8). As we have seen in Section 3.1, the parity-odd part vanishes.

By expanding Eq. (4.3) through to \( O(\epsilon^2) \), and labelling the coefficients of the terms of \( O(\epsilon) \) as

\[
\begin{align*}
VC_1(t_1, t_2) &= \zeta_3 - \operatorname{Li}_3 \left( \frac{t_1}{t_2} \right), \\
VC_2(t_1, t_2, \tau) &= \ln \frac{t_1}{t_2} \left( \operatorname{Li}_2 \left( \frac{t_1}{t_2} \right) + \zeta_2 \right) \\
&\quad + \frac{1}{3} \ln^3 \frac{-t_1}{\tau} - \frac{1}{2} \ln^2 \frac{-t_1}{\tau} \ln \frac{-t_2}{\tau} + \frac{1}{6} \ln^3 \frac{-t_2}{\tau}, \\
VC_3(t_1, t_2, \tau) &= \frac{1}{6} \ln^3 \frac{-t_1}{\tau} \ln \frac{-t_2}{\tau} - \frac{1}{8} \ln^4 \frac{-t_1}{\tau} - \frac{1}{24} \ln^4 \frac{-t_2}{\tau} \\
&\quad - \frac{1}{2} \left( \ln^2 \frac{-t_1}{\tau} - \ln^2 \frac{-t_2}{\tau} \right) \left( \operatorname{Li}_2 \left( \frac{t_1}{t_2} \right) + \zeta_2 \right),
\end{align*}
\]

the even part of the one-loop Lipatov vertex becomes

\[
V^{(1)}_e(t_1, t_2, \tau, \kappa) = -\frac{1}{\epsilon^2} \Gamma(1 + \epsilon) \Gamma(1 - \epsilon) \\
+ \left[ \left( \frac{\kappa}{t_1} \right)^\epsilon + \left( \frac{\kappa}{t_2} \right)^\epsilon \right] \left( -\frac{1}{\epsilon} \ln \frac{-\kappa}{\tau} + \epsilon VC_1(t_1, t_2) \right) \\
+ \left( -\frac{1}{2} \ln^2 \frac{t_1}{t_2} + \epsilon VC_2(t_1, t_2, \tau) \right) \left( \frac{-\kappa}{\tau} \right)^\epsilon + \epsilon^2 VC_3(t_1, t_2, \tau) + O(\epsilon^3).
\]

with the expansion of the first term given in Eq. (C.9).

The expansion of Eq. (4.4) through to \( O(\epsilon^2) \) is provided by the expansion of the functions \( I^{(IIa)}(\kappa, t_1, t_2) \) and \( I^{(I)}(\kappa, t_1, t_2) \) of Eq. (3.9) through to \( O(\epsilon) \) in terms of Goncharov’s multiple polylogarithms [1].

### 4.1 Analytic continuation of the one-loop vertex to the physical region

Using Eq. (2.37) and the prescription \( \ln(-\kappa) = \ln(\kappa) - i\pi \), for \( \kappa > 0 \), in the physical region where \( s, s_1, s_2 \) are positive and \( t_1, t_2 \) are negative, the parity-even part of the one-loop
Using the identity (C.9) and of the parity-odd part of the one-loop gluon-production vertex (4.4) is

\[
V^{(1)}_{\psi,\text{phys}}(t_1, t_2, \tau, \kappa) = \frac{1}{2} e^{i \pi \epsilon} \Gamma(1 + \epsilon) \Gamma(1 - \epsilon) \nonumber \\
+ \left( \frac{\kappa}{-t_1} \right)^\epsilon \left( \frac{\psi(1) - \psi(1 + \epsilon)}{\epsilon} + \frac{1}{\epsilon} \ln \frac{-t_1}{\tau} \right) + \left( \frac{\kappa}{-t_2} \right)^\epsilon \left( \frac{\psi(1) - \psi(-\epsilon)}{\epsilon} + \frac{1}{\epsilon} \ln \frac{-t_2}{\tau} \right) 
onumber \\
+ \frac{1}{\epsilon^2} \left( \frac{\kappa}{-t_1} \right)^\epsilon \left( \frac{\psi(1) - \psi(1 + \epsilon)}{\epsilon} + \frac{1}{\epsilon} \ln \frac{-t_1}{\tau} \right) + \left( \frac{\kappa}{-t_2} \right)^\epsilon \left( \frac{\psi(1) - \psi(-\epsilon)}{\epsilon} + \frac{1}{\epsilon} \ln \frac{-t_2}{\tau} \right) 
onumber \\
+ \frac{1}{\epsilon^2} \left( \frac{\kappa}{-t_1} \right)^\epsilon \left( \frac{\psi(1) - \psi(1 + \epsilon)}{\epsilon} + \frac{1}{\epsilon} \ln \frac{-t_1}{\tau} \right) + \left( \frac{\kappa}{-t_2} \right)^\epsilon \left( \frac{\psi(1) - \psi(-\epsilon)}{\epsilon} + \frac{1}{\epsilon} \ln \frac{-t_2}{\tau} \right) 
\]

(4.7)

Using the identity (C.9) and

\[
\pi \epsilon \frac{\cos(\pi \epsilon)}{\sin(\pi \epsilon)} = 1 + \epsilon (\psi(1 - \epsilon) - \psi(1 + \epsilon)),
\]

the real part of the parity-even one-loop gluon-production vertex becomes

\[
\text{Re } V^{(1)}_{\psi,\text{phys}}(t_1, t_2, \tau, \kappa) = -\frac{1 + \epsilon (\psi(1 - \epsilon) - \psi(1 + \epsilon))}{\epsilon^2} 
\]

\[
+ \left( \frac{\kappa}{-t_1} \right)^\epsilon \left( \frac{\psi(1) - \psi(1 + \epsilon)}{\epsilon} + \frac{1}{\epsilon} \ln \frac{-t_1}{\tau} \right) + \left( \frac{\kappa}{-t_2} \right)^\epsilon \left( \frac{\psi(1) - \psi(-\epsilon)}{\epsilon} + \frac{1}{\epsilon} \ln \frac{-t_2}{\tau} \right) 
\]

\[
+ \frac{1}{\epsilon^2} \left( \frac{\kappa}{-t_1} \right)^\epsilon \left( \frac{\psi(1) - \psi(1 + \epsilon)}{\epsilon} + \frac{1}{\epsilon} \ln \frac{-t_1}{\tau} \right) + \left( \frac{\kappa}{-t_2} \right)^\epsilon \left( \frac{\psi(1) - \psi(-\epsilon)}{\epsilon} + \frac{1}{\epsilon} \ln \frac{-t_2}{\tau} \right) 
\]

\[
- \frac{1}{\epsilon} \left[ \left( \frac{\kappa}{-t_1} \right)^\epsilon + \left( \frac{\kappa}{-t_2} \right)^\epsilon \right] \left[ \ln \frac{-t_1}{\tau} + \ln \frac{t_1 - t_2}{\tau} \right],
\]

(4.9)

which can readily expanded in \( \epsilon \) like in Eqs. (4.5) and (4.6).

The imaginary part is given by

\[
\text{Im } V^{(1)}_{\psi,\text{phys}}(t_1, t_2, \tau, \kappa) = \frac{\pi}{\epsilon} \left\{ -1 + \left( \frac{\kappa}{-t_1} \right)^\epsilon + \left( \frac{\kappa}{-t_2} \right)^\epsilon \right\},
\]

(4.10)

Taking into account the sign flip of the spin structure (3.7), the analytic continuation of the parity-odd part of the one-loop gluon-production vertex (4.4) is

\[
V^{(1)}_{\psi,\text{phys}}(t_1, t_2, \tau, \kappa) = -\epsilon G(\epsilon) s \left( p_{3\perp} p_{4\perp}^* - p_{4\perp} p_{3\perp}^* \right) P_{\text{phys}},
\]

(4.11)

where the function \( P_{\text{phys}} \) is,

\[
P_{\text{phys}} = \begin{cases} 
\frac{1}{s_1 s_2} T_{\text{phys}}^{(I\perp)}(\kappa, t_1, t_2) & \text{for } -\frac{s_1 s_2}{s_1 s_2} + \frac{s_1 s_2}{s_1 s_2} > 1 \text{ and } -t_1 < -t_2, \\
\frac{1}{s_1 s_2} T_{\text{phys}}^{(I\perp)}(\kappa, t_1, t_2) & \text{for } \frac{s_1 s_2}{s_1 s_2} + \frac{s_1 s_2}{s_1 s_2} < 1.
\end{cases}
\]

(4.12)
The analytic continuation (2.35) implies that the ratios \( y_1 \) and \( y_2 \), Eq. (3.11), are continued as,

\[
(-y_1) \to e^{-i\pi} y_1, \quad y_2 \to y_2, \quad (4.13)
\]

and the functions \( \mathcal{I}_{\text{phys}}^{(I,II)}(\kappa, t_1, t_2) \) are continued according to Eq. (2.37). Then Eq. (3.10) is continued to,

\[
\mathcal{I}_{\text{phys}}^{(IIa)}(\kappa, t_1, t_2) = -e^{i\pi\epsilon} \frac{1}{\epsilon^3} y_2^{-\epsilon} \Gamma(1 - 2\epsilon) \Gamma(1 + \epsilon)^2 F_4\left(1 - 2\epsilon, 1 - \epsilon, 1 - \epsilon, 1 - \epsilon, -y_1, y_2\right) + e^{i\pi\epsilon} \frac{1}{\epsilon^3} \Gamma(1 + \epsilon) \Gamma(1 - \epsilon) F_4\left(1, 1 - \epsilon, 1 - \epsilon, 1 + \epsilon, -y_1, y_2\right) - \frac{1}{\epsilon^2} (-y_1)^{\epsilon} y_2^{-\epsilon} \left\{ \left[ \ln(-y_1) + i\pi + \psi(1 - \epsilon) - \psi(-\epsilon) \right] F_4\left(1, 1 - \epsilon, 1 + \epsilon, 1 - \epsilon; -y_1, y_2\right) + \frac{\partial}{\partial \delta} F_{0,2}^{2,1} \left(1 + \delta 1 + \delta - \epsilon | 1 + \delta 1 - \epsilon 1 + \epsilon + \delta - - - - - - - y_1, y_2\right) \right\} + \frac{1}{\epsilon^2} (-y_1)^{\epsilon} \left\{ \left[ \ln(-y_1) - i\pi + \psi(1 + \epsilon) - \psi(-\epsilon) \right] F_4\left(1, 1 + \epsilon, 1 + \epsilon, 1 - \epsilon; -y_1, y_2\right) + \frac{\partial}{\partial \delta} F_{0,2}^{2,1} \left(1 + \delta 1 + \delta + \epsilon | 1 + \delta 1 + \epsilon 1 + \epsilon + \delta - - - - - - - y_1, y_2\right) \right\}, \quad (4.14)
\]

where the Appell and the Kampé de Fériet functions stay real in the analytic continuation [1]. Like in the Euclidean region in Section 3, in Eq. (4.14) all the poles in \( \epsilon \) cancel. Eq. (4.14) may be expanded in \( \epsilon \) in terms of real \( \mathcal{M} \) functions, introduced in Ref. [1]. It could also be expanded in terms of Goncharov’s multiple polylogarithms, to the price, though, of introducing a complicated and fictitious analytic structure: the Goncharov’s polylogarithms would occur with several spurious imaginary parts, which ultimately would have to cancel in order to respect the fact that the Appell and the Kampé de Fériet functions are real.
Using the identities (4.8) and (C.9), the real part of the function \( T_{\text{phys}}^{(IIa)}(\kappa, t_1, t_2) \) is

\[
\text{Re} T_{\text{phys}}^{(IIa)}(\kappa, t_1, t_2)
\]

\[
= -y_2^{-\epsilon} \frac{1 + \epsilon (\psi(1 - \epsilon) - \psi(1 + \epsilon))}{\epsilon^3} \frac{\Gamma(1 - 2\epsilon) \Gamma(1 + \epsilon)}{\Gamma(1 - \epsilon)} F_4 \left( 1 - 2\epsilon, 1 - \epsilon, 1 - \epsilon; -y_1, y_2 \right)
\]

\[
+ \frac{1 + \epsilon (\psi(1 - \epsilon) - \psi(1 + \epsilon))}{\epsilon^3} F_4 \left( 1, 1 - \epsilon, 1 - \epsilon, 1 + \epsilon; -y_1, y_2 \right)
\]

\[
- (-y_1)^{\epsilon} y_2^{\epsilon} \frac{1}{\epsilon^2} \left\{ \ln(-y_1) + \psi(1 - \epsilon) - \psi(-\epsilon) \right\} F_4 \left( 1, 1 - \epsilon, 1 + \epsilon, 1 - \epsilon; -y_1, y_2 \right)
\]

\[
+ \frac{\partial}{\partial \delta} F_{0,2}^{2,1} \left. \left( 1 + \delta \right) \frac{1 + \delta + \epsilon}{1 + \delta} \right|_{\delta = 0} F_4 \left( 1, 1 + \epsilon, 1 + \epsilon, 1 - \epsilon; -y_1, y_2 \right)
\]

\[
+ (-y_1)^{\epsilon} y_2^{-\epsilon} \left\{ \ln(-y_1) + \psi(1 + \epsilon) - \psi(-\epsilon) \right\} F_4 \left( 1, 1 + \epsilon, 1 + \epsilon, 1 + \epsilon; -y_1, y_2 \right)
\]

\[
+ \frac{\partial}{\partial \delta} F_{0,2}^{2,1} \left. \left( 1 + \delta \right) \frac{1 + \delta + \epsilon}{1 + \delta} \right|_{\delta = 0} F_4 \left( 1, 1 + \epsilon, 1 + \epsilon, 1 + \epsilon; -y_1, y_2 \right)
\]

which, if desired, may be expanded in \( \epsilon \) in terms of real \( \mathcal{M} \) functions.

The imaginary part is

\[
\text{Im} T_{\text{phys}}^{(IIa)}(\kappa, t_1, t_2)
\]

\[
= \frac{\pi}{\epsilon^2} \left\{ -y_2^{-\epsilon} \frac{\Gamma(1 - 2\epsilon) \Gamma(1 + \epsilon)}{\Gamma(1 - \epsilon)} F_4 \left( 1 - 2\epsilon, 1 - \epsilon, 1 - \epsilon; -y_1, y_2 \right)
\]

\[
+ F_4 \left( 1, 1 - \epsilon, 1 - \epsilon, 1 + \epsilon; -y_1, y_2 \right)
\]

\[
+ (-y_1)^{\epsilon} y_2^{-\epsilon} F_4 \left( 1, 1 - \epsilon, 1 + \epsilon, 1 - \epsilon; -y_1, y_2 \right)
\]

\[
- (-y_1)^{\epsilon} F_4 \left( 1, 1 + \epsilon, 1 + \epsilon, 1 + \epsilon; -y_1, y_2 \right) \right\}
\]

\[
(4.15)
\]

The Appell functions in Eq. (4.16) are all reducible to Gauss’ hypergeometric function. We find

\[
\text{Im} T_{\text{phys}}^{(IIa)}(\kappa, t_1, t_2)
\]

\[
= \frac{\pi}{\epsilon^2} \frac{1}{\sqrt{\lambda(1, -y_1, y_2)}} \left\{ -y_2^{-\epsilon} \frac{\Gamma(1 - 2\epsilon) \Gamma(1 + \epsilon)}{\Gamma(1 - \epsilon)} \lambda(1, -y_1, y_2)^{\epsilon}
\]

\[
+ 2 F_1 \left( 1, 2\epsilon, 1 + \epsilon; \frac{(1 - \lambda_1) \lambda_2}{1 - \lambda_1 \lambda_2} \right)
\]

\[
+ (-y_1)^{\epsilon} y_2^{-\epsilon} 2 F_1 \left( 1, 2\epsilon, 1 + \epsilon; \frac{\lambda_1 (1 - \lambda_2)}{1 - \lambda_1 \lambda_2} \right)
\]

\[
- (-y_1)^{\epsilon} 2 F_1 \left( 1, 2\epsilon, 1 + \epsilon; \frac{\lambda_1 \lambda_2}{1 - \lambda_1 \lambda_2} \right) \right\}
\]

\[
(4.17)
\]
where \( \lambda \) denotes the Källen function, \( \lambda(x, y, z) = x^2 + y^2 + z^2 - 2xy - 2xz - 2yz \), and

\[
\begin{align*}
\lambda_1 &= -\frac{1}{2y_1}(y_2 - y_1 - 1 + \sqrt{\lambda(1, -y_1, y_2)}) \\
\lambda_2 &= \frac{1}{2y_2}(y_2 - y_1 - 1 + \sqrt{\lambda(1, -y_1, y_2)}). 
\end{align*}
\] (4.18)

The hypergeometric function can be expanded into a Taylor series in \( \epsilon \),

\[
2F_1(1, 2\epsilon, 1 + \epsilon; z) = 1 - 2\epsilon \ln(1 - z) + 2\epsilon^2 \left( \frac{1}{2} \ln^2(1 - z) - \text{Li}_2(z) \right) + \mathcal{O}(\epsilon^3). \] (4.19)

5. The two-loop gluon-production vertex

In terms of parity-even and odd contributions, the two-loop gluon-production vertex is

\[
V^{(2)}(t_1, t_2, \tau, \kappa) = V_e^{(2)}(t_1, t_2, \tau, \kappa) + V_o^{(2)}(t_1, t_2, \tau, \kappa). \] (5.1)

Using Eq. (4.1) and the iteration formula (2.32), Eq. (5.1) becomes

\[
\begin{align*}
V_e^{(2)}(\epsilon) &= \frac{1}{2} \left[ V_e^{(1)}(\epsilon) \right]^2 + 2\frac{G^2(\epsilon)}{G(2\epsilon)} f^{(2)}(\epsilon) V_e^{(1)}(2\epsilon) + \mathcal{O} (\epsilon), \\
V_o^{(2)}(\epsilon) &= V_e^{(1)}(\epsilon) V_o^{(1)}(\epsilon) + \mathcal{O} (\epsilon),
\end{align*}
\] (5.2) (5.3)

where the parity-even and odd parts of the one-loop gluon-production vertex must be known through to \( \mathcal{O}(\epsilon^2) \). We used the fact that \( V_o^{(1)}(\epsilon) = \mathcal{O}(\epsilon) \), so it does not contribute to the square of the one-loop vertex in Eq. (5.2), and to the term proportional to \( f^{(2)} \) in Eq. (5.3).

In the unphysical Euclidean region (2.14), Eq. (5.2) becomes

\[
\begin{align*}
V_e^{(2)}(t_1, t_2, \tau, \kappa) &= \frac{1}{2\epsilon^4} \left( \frac{\pi \epsilon}{\sin(\pi \epsilon)} \right)^2 - 2\frac{G^2(\epsilon)}{G(2\epsilon)} f^{(2)}(\epsilon) \frac{1}{4\epsilon^2} \frac{2\pi \epsilon}{\sin(2\pi \epsilon)} \\
&+ \frac{1}{8} \ln \frac{t_1}{t_2} - \text{VC}_3(t_1, t_2, \tau) + \zeta_2 \ln^2 \frac{t_1}{t_2} \\
&+ \left[ \left( \frac{\kappa}{t_1} \right)^{2\epsilon} + \left( \frac{\kappa}{t_2} \right)^{2\epsilon} \right] \left[ \frac{1}{2\epsilon^2} \ln^2 \frac{-\kappa}{\tau} - \frac{1}{\epsilon} f^{(2)}(\epsilon) + \text{VC}_1(t_1, t_2) \right] \ln \frac{-\kappa}{\tau} \\
&+ \left[ \left( \frac{\kappa}{t_1} \right)^\epsilon \left( \frac{\kappa}{t_2} \right)^\epsilon \frac{\pi \epsilon}{\sin(\pi \epsilon)} \right] \left[ \frac{1}{\epsilon^2} \ln^2 \frac{-\kappa}{\tau} - 2 \ln \frac{-\kappa}{\tau} \text{VC}_1(t_1, t_2) \right] \\
&- \left[ \left( \frac{\kappa}{t_1} \right)^\epsilon + \left( \frac{\kappa}{t_2} \right)^\epsilon \frac{\pi \epsilon}{\sin(\pi \epsilon)} \right] \left[ \frac{1}{\epsilon} \ln \frac{-\kappa}{\tau} + \epsilon \text{VC}_1(t_1, t_2) \right] \\
&+ \left[ \left( \frac{-\kappa}{t_1} \right)^\epsilon + \left( \frac{-\kappa}{t_2} \right)^\epsilon \right] \left[ \frac{1}{\epsilon^2} \ln^2 \frac{-\kappa}{\tau} + \epsilon \text{VC}_2(t_1, t_2, \tau) \right] \\
&+ \left( \frac{-\kappa}{\tau} \right)^\epsilon \frac{\pi \epsilon}{\sin(\pi \epsilon)} \left[ \frac{1}{2} \ln^2 \frac{t_1}{t_2} + \epsilon \text{VC}_2(t_1, t_2, \tau) \right] + \mathcal{O} (\epsilon),
\end{align*}
\] (5.4)
where we have used Eq. (4.6) and collected the terms according to the different analytic structures.

The parity-odd part of the two-loop gluon-production vertex, \( V_o^{(2)}(t_1, t_2, \tau, \kappa) \), starts at \( \mathcal{O}(\epsilon^{-1}) \) and is given by the product of Eqs. (4.3) and (4.4).

The analytic continuation of the two-loop gluon-production vertex to the physical region where \( s, s_1, s_2 \) are positive and \( t_1, t_2 \) are negative, may be performed as in Section 4.1.

6. Conclusions

In this paper we have computed the one-loop five-point amplitude \( m_5^{(1)} \) in the planar \( \mathcal{N} = 4 \) supersymmetric Yang-Mills theory in the multi-Regge kinematics, using the calculation of the one-loop pentagon in \( D = 6 - 2\epsilon \) performed in a companion paper [1]. We have presented \( m_5^{(1)} \) in the Euclidean region (2.15) as an expression to all orders in \( \epsilon \) in terms of parity-even, Eq. (3.4), and parity-odd contributions, Eq. (3.8), starting at \( \mathcal{O}(\epsilon^{-2}) \) and at \( \mathcal{O}(\epsilon) \), respectively.

Using the high-energy factorisation for colour-stripped amplitudes, we have computed the one-loop gluon-production vertex to all orders in \( \epsilon \) in Eqs. (4.3) and (4.4). Because the high-energy coefficient functions and the Regge trajectory are parity-even, the parity-odd part of the one-loop gluon-production vertex equals the parity-odd part of the one-loop five-point amplitude, and thus appears at \( \mathcal{O}(\epsilon) \). The Laurent expansion in \( \epsilon \) through to \( \mathcal{O}(\epsilon^2) \) is given in Eq. (4.6) for the parity-even part, and in Ref. [1] for the parity-odd part in terms of Goncharov’s multiple polylogarithms. In Eqs. (4.7) and (4.11), we have continued analytically the all-orders-in-\( \epsilon \) one-loop gluon-production vertex to the physical region. The even-parity part may be easily expanded in \( \epsilon \); the odd-parity part may be more conveniently expanded in \( \epsilon \) in terms of real \( M \) functions, as in Ref. [1].

The iterative structure of the two-loop five-point amplitude implied by the BDS ansatz, together with the high-energy factorisation, implies an iterative structure of the gluon-production vertex. Thus, the knowledge of the one-loop gluon-production vertex through to \( \mathcal{O}(\epsilon^2) \), allows us to perform the first computation of the two-loop gluon-production vertex through to finite terms, which we present in Eq. (5.4) as an expansion starting at \( \mathcal{O}(\epsilon^{-4}) \). The parity-odd part of the two-loop gluon-production vertex appears at \( \mathcal{O}(\epsilon^{-1}) \) and is given by the product of Eqs. (4.3) and (4.4).\(^1\)

If augmented by the soft-limit contribution to \( \mathcal{O}(\epsilon) \), which is as yet unknown, the two-loop gluon-production vertex could be used as one of the building blocks of the kernel of a BFKL equation at next-to-next-to-leading logarithmic (NNLL) accuracy. The other building blocks are the three-loop Regge trajectory [6, 30, 31, 32], the one-loop vertex for the emission of two gluons along the ladder (computed in [30] only for two gluons of the same helicity) and the tree vertex for the emission of three gluons along the ladder [33, 34].

\(^1\)In Ref. [30] the logarithm of the gluon-production vertex has been introduced. If exponentiated, it yields at two-loop order the poles in \( \epsilon \) through to \( \mathcal{O}(\epsilon^{-2}) \), but it misses the single poles in \( \epsilon \), as well as the finite terms. Accordingly, it lacks completely the parity-odd contribution.

A. Multi-parton kinematics

We consider the production of three gluons of outgoing momentum \( p_i \), with \( i = 3, \ldots, 5 \) in the scattering between two gluons of ingoing momenta \( p_1 \) and \( p_2 \).

Using light-cone coordinates \( p^\pm = p_0 \pm p_z \), and complex transverse coordinates \( p_\perp = p^x + ip^y \), with scalar product \( 2p \cdot q = p^+ q^- + p^- q^+ - p_\perp q_\perp = p_\perp^* q_\perp \), the 4-momenta are,

\[
\begin{align*}
p_1 &= (p_1^- / 2, 0, 0, p_1^+ / 2) \equiv (0, p_1^1 ; 0, 0), \\
p_i &= ((p_i^+ + p_i^-) / 2, \text{Re}[p_i \perp], \text{Im}[p_i \perp], (p_i^+ - p_i^-) / 2) \\
&\equiv (\left| p_i \perp \right| e^{i\gamma}, \left| p_i \perp \right| e^{-i\gamma}, \left| p_i \perp \right| \cos \phi_i, \left| p_i \perp \right| \sin \phi_i),
\end{align*}
\] (A.1)

where \( y \) is the rapidity. The first notation above is the standard representation \( p^\mu = (p^0, p^x, p^y, p^z) \), while in the second we have the + and - components on the left of the transverse components. In the following, if not differently stated, \( p_i \) and \( p_j \) are always understood to lie in the range \( 3 \leq i, j \leq n \). The mass-shell condition is \( \left| p_i \perp \right|^2 = p_i^+ p_i^- \). Using momentum conservation,

\[
0 = \sum_{i=3}^{5} p_i \perp, \quad p_2^+ = -\sum_{i=3}^{5} p_i^+, \quad p_1^- = -\sum_{i=3}^{5} p_i^-, \quad (A.2)
\]

the Mandelstam invariants may be written as,

\[
s_{ij} = 2p_i \cdot p_j = p_i^+ p_j^- + p_i^- p_j^+ - p_\perp j^\perp \perp - p_\perp j^\perp \perp, \quad (A.3)
\]

so that

\[
\begin{align*}
s &= 2p_1 \cdot p_2 = \sum_{i,j=3}^{5} p_i^+ p_j^- , \\
s_{2i} &= 2p_2 \cdot p_i = -\sum_{j=3}^{5} p_i^- p_j^+ , \quad (A.4) \\
s_{1i} &= 2p_1 \cdot p_i = -\sum_{j=3}^{5} p_i^+ p_j^- .
\end{align*}
\]

\(^{5}\)By convention we consider the scattering in the unphysical region where all momenta are taken as outgoing, and then we analytically continue to the physical region where \( p_1^+ < 0 \) and \( p_2^+ < 0 \).
Using the spinor representation of Ref. [33],

\[
\begin{align*}
\psi_+ (p_i) &= \begin{pmatrix}
\sqrt{p_i^+} \\
\sqrt{p_i^+} e^{i\phi_i} \\
0 \\
0
\end{pmatrix}, \\
\psi_- (p_i) &= \begin{pmatrix}
0 \\
0 \\
\sqrt{-p_i^+} \\
-\sqrt{-p_i^+}
\end{pmatrix}, \\
\psi_+ (p_2) &= i \begin{pmatrix}
\sqrt{-p_2^+} \\
0 \\
0 \\
0
\end{pmatrix}, \\
\psi_- (p_2) &= i \begin{pmatrix}
0 \\
0 \\
\sqrt{-p_2^+} \\
-\sqrt{-p_2^+}
\end{pmatrix}, \\
\psi_+ (p_1) &= -i \begin{pmatrix}
0 \\
\sqrt{-p_1^+} \\
0 \\
0
\end{pmatrix}, \\
\psi_- (p_1) &= -i \begin{pmatrix}
0 \\
0 \\
\sqrt{-p_1^+} \\
0
\end{pmatrix},
\end{align*}
\]

(A.5)

for the momenta (A.1)*, the spinor products are

\[
\begin{align*}
\langle 21 \rangle &= -\sqrt{s}, \\
\langle 2i \rangle &= -i \sqrt{\frac{-p_2^+}{p_i^+}} p_{i\perp}, \\
\langle i1 \rangle &= i \sqrt{-p_i^- p_i^+}, \\
\langle ij \rangle &= p_{i\perp} \sqrt{\frac{p_j^+}{p_i^+}} - p_{j\perp} \sqrt{\frac{p_i^+}{p_j^+}},
\end{align*}
\]

(A.6)

where we have used the mass-shell condition \( |p_{i\perp}|^2 = p_{i\perp}^2 p_i^+ \).

B. Multi-Regge kinematics

In the multi-Regge kinematics, we require that the gluons are strongly ordered in rapidity and have comparable transverse momentum (2.1). This is equivalent to require a strong ordering of the light-cone coordinates,

\[
p_3^+ \gg p_4^+ \gg p_5^+; \quad p_3^- \ll p_4^- \ll p_5^-.
\]

(B.1)

Momentum conservation (A.2) then becomes

\[
0 = \sum_{i=3}^{5} p_{i\perp}, \quad p_2^+ \simeq -p_3^+, \quad p_1^- \simeq -p_5^-.
\]

(B.2)

*The spinors of the incoming partons must be continued to negative energy after the complex conjugation, e.g. \( \bar{\psi}_+ (p_2) = i \left( \sqrt{-p_2^+}, 0, 0, 0 \right) \).
where the ≃ sign is understood to mean “equals up to corrections of next-to-leading accuracy”. The Mandelstam invariants (A.4) are reduced to,

\[ s = 2p_1 \cdot p_2 \simeq p_3^+ p_5^-, \]
\[ s_{2i} = 2p_2 \cdot p_i \simeq -p_3^+ p_i^-, \]
\[ s_{1i} = 2p_1 \cdot p_i \simeq -p_3^+ p_5^-, \]
\[ s_{ij} = 2p_i \cdot p_j \simeq p_i^+ p_j^- \quad i < j. \] 

(B.3)

The product of the two successive invariants \( s_{34} \) and \( s_{45} \) fixes the mass shell of gluon 4,

\[ s_{34} s_{45} \simeq p_3^+ p_4^- p_4^+ p_5^- = |p_{4\perp}|^2 p_3^+ p_5^- \simeq |p_{4\perp}|^2 s. \]

Thus,

\[ |p_{4\perp}|^2 = \frac{s_{34} s_{45}}{s}. \] 

(B.4)

The spinor products (A.6) are,

\[ \langle 21 \rangle \simeq -\sqrt{p_3^+ p_5^-}, \]
\[ \langle 2i \rangle \simeq -i \sqrt{p_i^+ p_{i\perp}}, \]
\[ \langle i1 \rangle \simeq i \sqrt{p_i^+ p_5^-}, \]
\[ \langle ij \rangle \simeq -\sqrt{p_i^+ p_j^-} \quad \text{for } y_i > y_j. \] 

(B.5)

C. The soft limit of the one-loop five-point amplitude

We consider the five–point amplitude of Sect. 2.2, and take the limit where the intermediate gluon becomes soft, \( p_4 \to 0 \). In this limit, the one-loop five-point amplitude factorises as [19, 35],

\[
\lim_{p_4 \to 0} m_5^{1\text{-loop}}(1, 2, 3, 4^\lambda, 5) = \text{Soft}^{\text{tree}}(3, 4^\lambda, 5) m_4^{1\text{-loop}}(1, 2, 3, 5) + \text{Soft}^{1\text{-loop}}(3, 4^\lambda, 5) m_4^{\text{tree}}(1, 2, 3, 5) \tag{C.1}
\]

where the one-loop soft-gluon function, to all orders of \( \epsilon \), is

\[
\text{Soft}^{1\text{-loop}}(3, 4^\lambda, 5) = -g^2 1 \epsilon^2 \frac{\pi \epsilon}{\sin(\pi \epsilon)} \left( \frac{\mu^2 (-s_{35})}{(-s_{34})(-s_{45})} \right)^\epsilon \text{Soft}^{\text{tree}}(3, 4^\lambda, 5) \tag{C.2}
\]

and the tree-level soft function is

\[
\text{Soft}^{\text{tree}}(3, 4^+, 5) = \frac{\langle 35 \rangle}{\langle 34 \rangle \langle 45 \rangle}. \tag{C.3}
\]

For the MHV amplitude we are considering, the soft limit for a negative helicity gluon is trivial and is obtained from this by helicity reversal. In the multi-Regge kinematics (2.15),
\[ s_{35} = s; \] then, using the on-shell condition (2.16) and the normalisation of Eq. (2.21), the soft-gluon limit of the one-loop five-point coefficient becomes
\[
\lim_{p_4 \to 0} m_5^{(1)}(1, 2, 3, 4, 5) = m_4^{(1)}(1, 2, 3, 5) - \frac{1}{\epsilon^2} \frac{\pi \epsilon}{\sin(\pi \epsilon)} \left( \frac{\mu^2}{-\kappa} \right)^\epsilon, \tag{C.4}
\]
where we have factored out
\[
\lim_{p_4 \to 0} m_5^{(0)}(1, 2, 3, 4^\lambda, 5) = m_4^{(0)}(1, 2, 3, 5) \text{SoftTree}(3, 4^\lambda, 5). \tag{C.5}
\]
In addition, in the soft limit of gluon 4, we can write the one-loop coefficient (2.22) as,
\[
\lim_{\kappa \to 0} m_5^{(1)}(1, 2, 3, 4, 5) = m_4^{(1)}(1, 2, 3, 5) + \tilde{\alpha}^{(1)}(t) \ln \frac{-\kappa}{\tau} + \lim_{\kappa \to 0} \tilde{V}^{(1)}(t, t, \tau, \kappa), \tag{C.6}
\]
with \( t_1 = t_2 = t \) and
\[
m_4^{(1)} = \tilde{\alpha}^{(1)}(t) \ln \frac{-s}{\tau} + 2 \tilde{C}^{(1)}(t, \tau). \tag{C.7}
\]
Equating Eqs. (C.4) and (C.6) and using Eqs. (2.20) and (2.23), we obtain the soft limit of the one-loop gluon-production vertex, to all orders of \( \epsilon \) [18],
\[
\lim_{\kappa \to 0} V^{(1)}(t, t, \tau, \kappa) = \frac{1}{\epsilon^2} \frac{\pi \epsilon}{\sin(\pi \epsilon)} - \frac{2}{\epsilon} \left( \frac{\kappa}{t} \right)^\epsilon \ln \frac{-\kappa}{\tau}, \tag{C.8}
\]
with
\[
\frac{\pi \epsilon}{\sin(\pi \epsilon)} = \frac{\pi^2}{6} + \frac{7}{4} \zeta_4 \epsilon^2 + 3 \frac{1}{4} \zeta_6 \epsilon^4 + \cdots = \sum_{n=0}^\infty c_n \epsilon^{2n}, \quad \text{with} \quad c_0 = 1, \quad c_n = \frac{22^{n-1} - 1}{2^{2(n-1)}} \zeta_{2n}. \tag{C.9}
\]
