The aPKC\(\text{\textsubscript{i}}\) blocking agent ATM negatively regulates EMT and invasion of hepatocellular carcinoma

CQ Ma\(\text{\textsuperscript{1}},\) Y Yang\(\text{\textsuperscript{1}},\) JM Wang\(\text{\textsuperscript{1,2}},\) GS Du\(\text{\textsuperscript{2}},\) Q Shen\(\text{\textsuperscript{1}},\) Y Liu\(\text{\textsuperscript{1}},\) J Zhang\(\text{\textsuperscript{1}},\) JL Hu\(\text{\textsuperscript{1}},\) P Zhu\(\text{\textsuperscript{1}},\) WP Qi\(\text{\textsuperscript{1}},\) YW Qian\(\text{\textsuperscript{1}}\) and Y Fu\(\text{\textsuperscript{1}}\)

Epithelial-to-mesenchymal transition (EMT) has an important role in invasion and metastasis of hepatocellular carcinoma (HCC). To explore the regulatory mechanism of atypical protein kinase C\(\text{\textsubscript{i}}\) (aPKC\(\text{\textsubscript{i}}\)) signaling pathways to HCC development, and find an agent for targeted therapy for HCC, immortalized murine hepatocytes were employed to establish an EMT cell model of HCC, MMH-RT cells. Our study showed that EMT took place in MMH-R cells under the effect of transforming growth factor-\(\beta\text{\textsubscript{1}}\) (TGF-\(\beta\text{\textsubscript{1}}\)) overexpressing aPKC\(\text{\textsubscript{i}}\). Furthermore, we showed that the aPKC\(\text{\textsubscript{i}}\) blocking agent aurothiomalate (ATM) inhibited EMT and decreased invasion of hepatocytes. Moreover, ATM selectively inhibited proliferation of mesenchymal cells and HepG2 cells and induced apoptosis. However, ATM increased proliferation of epithelial cells and had little effect on apoptosis and invasion of epithelial cells. In conclusion, our result suggested that aPKC\(\text{\textsubscript{i}}\) could be an important bio-marker of tumor EMT, and used as an indicator of invasion and malignancy. ATM might be a promising agent for targeted treatment of HCC.

Cell Death and Disease (2014) 5, e1129; doi:10.1038/cddis.2014.91; published online 20 March 2014

Subject Category: Cancer

In the last decade, hepatocellular carcinoma (HCC) is considered to be the most lethal of cancers, accounting for approximately one-third of all malignancies.\(\text{\textsuperscript{1,2}}\) HCC is curable by surgical resection or liver transplantation if diagnosed at early stage.\(\text{\textsuperscript{3}}\) However, the risk of 5-year recurrence of HCC following hepatic resection is as high as 50–70%, due to its high invasion and the frequent intra- and/or extra-hepatic metastases.\(\text{\textsuperscript{4}}\) Epithelial–mesenchymal transition (EMT) has been shown to be a pivotal mechanism contributing to cancer invasion and metastasis, as epithelial cells lose their polarity and acquire the migratory properties of mesenchymal cells. The characteristic changes during EMT include the down-regulation of epithelial markers, such as E-cadherin and the upregulation of mesenchymal markers such as vimentin.\(\text{\textsuperscript{5}}\) A correlation between the expression profiles of EMT, and tumor recurrence or distant metastasis, has been demonstrated in certain types of cancer, including HCC.\(\text{\textsuperscript{6–8}}\) Although several EMT-related transcription factors such as Snail, Twist, and Zinc finger E-box binding protein 1 (ZEB1) have been shown to be involved in the process of EMT in HCC,\(\text{\textsuperscript{9,10}}\) the molecular mechanisms underlying the regulation of EMT in HCC have not yet been fully elucidated.

Atypical protein kinase C\(\text{\textsubscript{i}}\) (aPKC\(\text{\textsubscript{i}}\)) is a newly discovered aPKC, which is independent of calcium, diacylglycerol, and is only activated by phospholipids. It is an important signaling molecule taking part in transformation, adhesion, movement, invasion, and metastasis of tumor cells.\(\text{\textsuperscript{11}}\) Recent studies indicated that aPKC\(\text{\textsubscript{i}}\) is the sole catalytic component of the Par3-Par6-aPKC\(\text{\textsubscript{i}}\) complex, which has a critical role in the establishment and maintenance of epithelial cell polarity, tight junctions, and adherens junctions.\(\text{\textsuperscript{12}}\) Importantly, loss of apical-basal cell polarity is essential for EMT, a critical step in cellular motility and invasion.\(\text{\textsuperscript{13}}\) Loss of polarity also allows several growth factors and receptors, which are normally compartmentalized because of tight junctions in polarized cells, to mediate autocrine cell activation.\(\text{\textsuperscript{14,15}}\)

We previously reported that aPKC\(\text{\textsubscript{i}}\) expression was higher at both mRNA and protein levels in HCC tissues (44 cases) than in peri-tumoral and normal tissues.\(\text{\textsuperscript{16}}\) Accumulation of aPKC\(\text{\textsubscript{i}}\) in HCC cytoplasm and nucleolus was found to be associated with the loss of polarity and tight junctions in cell–cell contact and E-cadherin was reduced and accumulation of cytoplasmic \(\beta\)-catenin increased in HCC.\(\text{\textsuperscript{16}}\) These observations suggest that overexpression of aPKC\(\text{\textsubscript{i}}\) may have an important role in the promotion of invasion and metastasis in HCC.\(\text{\textsuperscript{16}}\)

Therefore, we are lead to postulate that the aPKC\(\text{\textsubscript{i}}\), a key catalytic regulator of polarity and tight junctions, might serve as target for the treatment of HCC.

The current study examined the relation between aPKC\(\text{\textsubscript{i}}\) signaling pathway and the invasion and metastasis of HCC, with an attempt to identify a new target for the drug therapy of HCC. Immortalized murine hepatocytes (MMH-D3 cell line, obtained from Prof. Marco Tripodi, University La Sapienza, Roma, Italy) were used to establish a cell model of

hepatocellular tumor invasion and metastasis by treating the cells with oncogenic v-Ha-Ras in combination with transforming growth factor-\(\beta/1\) (TGF-\(\beta/1\)) signaling. The \textit{in vitro} model was verified by detecting the EMT markers and increased invasion of the cells. Specific blocking agent of aPKC\(_i\) signaling pathway, aurothiomalate (ATM), was used to inhibit the effects of aPKC\(_i\) on invasion, survival, and apoptosis of EMT cells (MMH-RT cells), and then the inhibitory effect was examined to explore the function of aPKC\(_i\) in HCC EMT and to find a target drug for HCC therapy and lay a foundation for further research.

Results

Effect of v-Ha-Ras and TGF-\(\beta/1\) on aPKC\(_i\) and EMT of hepatocytes. Epithelial MMH-D3 cells were infected with lentiviruses that bicistronically expressed constitutively active v-Ha-Ras and green fluorescent protein (GFP).\(^{17}\) Flow cytometrically separated GFP-positive cells expressing v-Ha-Ras protein in MMH-D3, MMH-R (24-h post transfection), and MMH-R (passage 1) cells were determined by western blot analysis using the anti-v-Ha-Ras antibody. The result showed that expression of v-Ha-Ras (21 kDa) was significantly higher in MMH-R (24-h post transfection) and MMH-R (passage 1) cells than in MMH-D3 parental cells, as shown in Figure 1a.

To establish a cell model with EMT phenotypes, MMH-R cells were then stimulated with TGF-\(\beta/1\) for 24 h (MMH-RT cells) and comparable growth rate between MMH-D3, MMH-R, and MMH-RT cells was observed (Figure 1b).\(^{18}\) In contrast, treatment of these parental MMH-D3 hepatocytes with 8 ng/ml TGF-\(\beta/1\) resulted in growth inhibition within 72 h. In the following 4 days (4–7 days), this cell growth was consistently inhibited (Figure 1b, Student's \(t\)-test, \(P<0.05\)). The epithelial and mesenchymal markers were examined by western blotting (Figures 1c and d). It was found that the expression of epithelial markers E-cadherin (135 kDa) and \(\beta\)-catenin (92 kDa) was significantly reduced in MMH-RT cells, compared with MMH-R cells (Student's \(t\)-test, \(P<0.01\)). With the loss of epithelial markers, expression of mesenchymal markers such as vimentin (53 kDa) was obviously increased in MMH-RT cells as compared with MMH-R cells (Figures 1c and d, Student's \(t\)-test, \(P<0.01\)). The subcellular distribution of E-cadherin and \(\beta\)-catenin was analyzed under an immunofluorescent microscope. As shown in Figure 1e, E-cadherin and \(\beta\)-catenin were localized at cell–cell junction in MMH-D3 cells (Figure 1el, III); however, in MMH-RT cells, E-cadherin was lost from cell boundaries and \(\beta\)-catenin was redistributed diffusely in cytoplasm (Figure 1el, IV). Consistent with the morphological changes in EMT, MMH-RT cells transformed into spindle shape from triangle form (Figure 1fI–III).

Loss of cell adhesion, disruption of the tight junction, unrestricted proliferation, and increase in mesenchymal markers and morphological changes of MMH-R cells induced by TGF-\(\beta/1\) all indicated that the phenotype of MMH-RT cells was transformed from epithelia into mesenchymal cells and obtain the unrestricted proliferation ability. We further detected aPKC\(_i\) (74 kDa) protein and aPKC\(_i\) was also apparently induced by TGF-\(\beta/1\) in MMH-RT cells, as was observed with vimentin (Figures 1c and d, Student's \(t\)-test, \(P<0.01\)). Therefore, MMH-RT cells can serve as a suitable model for the study of the invasion and metastasis of HCC regulated by aPKC\(_i\) signaling pathway.

Inhibitory effect of ATM on aPKC\(_i\) and PAR6 binding in PB1 domain. The recombinant plasmids, pET-15b/aPKC\(_i\) and pGEX-4t-3/PAR6, were constructed (Figure 2aI, II) and transformed into \textit{E. coli} (Supplementary Figure 1). The direct binding of PB1 domain of aPKC\(_i\) with PAR6 was verified with GST pull-down assay, and the interaction between aPKC\(_i\) and PAR6 was inhibited by ATM (Figure 2b). The interaction between aPKC\(_i\) and PAR6 was suppressed by ATM in a dose-dependent manner (Figures 2b and c), and the finding was consistent with previously reported results (Alan P Fields). The semiquantitative with western blotting and standardizing IOD showed that the mean binding ratio (n = 3) was 63.8% at 10 \(\mu\)M of ATM and 32.7% at 50 \(\mu\)M of ATM, respectively, when the ratio was set at 100% at 0 \(\mu\)M of ATM (Figure 2c). The IC50 of ATM was 20.42 \(\mu\)M.

To know whether the interaction between aPKC\(_i\) and PAR6 is also inhibited by ATM in MMH-RT cells, we performed co-immunoprecipitation (CO-IP). After 24-h treatment with ATM, an antibody against aPKC\(_i\) was used to immunoprecipitate Par6 protein from cell extracts. The isolated proteins were analyzed by western blotting by using an anti-Par6 antibody. The Par6 bands are shown in Figure 2d, which reveals that protein content dropped gradually with increasing concentration of ATM (the left-hand pictures). On the other hand, a Par6 antibody was used to precipitate aPKC\(_i\) protein and anti-aPKC\(_i\) antibody was employed to detect aPKC\(_i\). The result exhibited that protein content gradually decreased with increasing concentration of ATM (Figure 2d, the right-hand pictures). The interaction between aPKC\(_i\) and PAR6 was inhibited by ATM in a dose-dependent manner in MMH-RT cells. The mean binding ratios (n = 3), as semiquantitatively determined with western blotting, are shown in Figure 2e, with IOD standardized and the ratio at 0 \(\mu\)M of ATM defined as 100%. The IC50 of ATM was 295.05 \(\mu\)M with Par6 and 254.57 \(\mu\)M with aPKC\(_i\), respectively.

Partial inhibition of transition of epithelial cell markers to mesenchymal cell markers of MMH-RT cells by ATM. To assess the effect of the aPKC\(_i\) signaling pathway on EMT in HCC, we determined EMT markers and aPKC\(_i\) levels in ATM-treated MMH-RT cells (Figure 3a). After 48-h incubation, the expression of aPKC\(_i\) was gradually decreased with increasing concentration of ATM in MMH-RT cells (Figure 3b, Student's \(t\)-test, \(P<0.05\), \(P<0.01\)); the expression of N-cadherin was significantly decreased in MMH-RT cells (Figure 3b, Student's \(t\)-test, \(P<0.05\)); the expression of \(\beta\)-catenin was slightly increased in MMH-RT cells (Figure 3b, Student's \(t\)-test, \(P<0.05\)); the expression of E-cadherin was slightly increased in MMH-RT cells (Figure 3b, Student's \(t\)-test, \(P<0.05\)). Additionally, the expression of vimentin remained unchanged in MMH-RT cells, and bore no association with ATM levels (Figure 3b). These results suggested that the ATM could partially inhibit EMT transition in MMH-RT cells.
Inhibition of viability and invasion of mesenchymal MMH-RT cells by ATM. It was previously shown that ATM was an effective proliferation inhibitor of aPKC signaling in non-small lung cancer (NSCLC) cells. In this study, we focused on the inhibitory effect of aPKC signaling by ATM on HCC EMT cells. The cell counting kit-8 (CCK8) assay showed that the survival rate of MMH-RT cells decreased rapidly with increasing concentrations and time of ATM treatment (Figures 4a–c). In all, 24, 48, and 72 h after the incubation, the IC50 of MMH-RT cells was 8582.87, 612.98, and 483.68 μmol/l, respectively. In contrast, the stimulating effect of ATM on cell proliferation of epithelial MMH-R cells increased with the time of ATM treatment; but the cell proliferation-stimulating effect was not conspicuously correlated with concentration in the concentration range used in this experiment (Figures 4a–c).

The effects of ATM on invasion of MMH-R and MMH-RT cells were evaluated by transwell assay. After induction with TGF-β1, the invasion was significantly increased in mesenchymal MMH-RT cells than in epithelial MMH-R cells (Figures 4d, 5).
II and e, Student’s t-test, P < 0.01). The ATM inhibited the invasion of MMH-R cells and MMH-RT cells in a dose-dependent manner in the range of 1–100 μmol/l (Figures 4d and e). However, the sensitivity of MMH-RT cells to ATM was much higher than that of the MMH-R cells. When treated with 10 μmol/l ATM, MMH-R and MMH-RT cells showed similar invasion (Figures 4dIII, IV and e). However, higher concentration of ATM (100 μmol/l) significantly decreased the invasion in MMH-RT cells than in MMH-R cells (Figures 4dV, VI and e, Student’s t-test, P < 0.01). However, no effect of ATM on the morphological change of the cells was observed (Figure 4d). These findings indicated that the aPKC\textsubscript{i} signaling inhibitor could significantly suppressed the proliferation and invasion of mesenchymal MMH-RT cells.

Induction of apoptosis of mesenchymal MMH-RT cells by ATM. ATM-induced apoptosis in 48 h was detected by fluorescence activated cell sorter (FACS) (Figure 5a).
The results suggested that ATM had a strong inhibitory effect on hepatocarcinoma cells overexpressing aPKCi.

**Discussion**

To examine the role of aPKCi in invasion and metastasis and outcome of HCC, our previous studies exhibited that the gene and protein expressions of aPKCi are obviously higher in HCC tissues than in peri-tumor tissues and normal tissues. Accumulation of aPKCi in HCC cytoplasm and nucleoli was associated with the loss of polarity and tight junctions in cell–cell contact. However, we also found that E-cadherin was reduced and accumulation of cytoplasmic β-catenin was increased in HCC. These studies led us to postulate that the overexpression of aPKCi may have a critical role in the regulation of EMT in HCC. To explore the roles of aPKCi, we constructed an EMT cell model of HCC. These untransformed murine cells, generated from liver explants of transgenic mice expressing a constitutively active truncated form of the human cyto-Met, stably grow in vitro and display characteristics typical of hepatocytes as indicated by morphological, ultrastructural, cytochemical, and functional criteria. In addition, these MMH-D3 cells retain epithelial cell polarity, express hepatocyte-enriched transcription factors and hepatic markers, and maintain their highly differentiated program throughout multiple cell divisions. Furthermore, MMH-D3 cells have been previously well characterized as model of TGF-β1-induced reversible EMT, in which the master regulators Snail and HNF4a have key roles.

Our study showed that TGF-β1 worked with constitutively active v-Ha-Ras to induce and maintain EMT. This process is accompanied by aPKCi overexpression. Meanwhile, we also found that ATM could block aPKCi-Par6 complexes in vitro and affect the biological features of MMH-RT. ATM efficiently inhibited transition of epithelial cell markers to mesenchymal cell markers, viability and invasion, but promoted apoptosis of mesenchymal MMH-RT cells. These findings indicated that ATM has more potent inhibitory effect on mesenchymal cells than on epithelial cells. Interestingly, ATM could also significantly inhibit HepG2 cells, a human hepatocarcinoma cell line, which overexpresses aPKCi. Moreover, our research also showed that ATM could dose-dependently decrease the expression of aPKCi in mesenchymal MMH-RT cells. These results proved our hypothesis that aPKCi signaling pathway is essential for efficient TGF-β1-induced EMT of HCC cells, and inhibition of aPKCi signaling pathway might be an alternative for the treatment of HCC.

It was previously reported that aPKCi drives transforming growth and invasion of NSCLC cells through activation of a proliferative aPKCi-Par6-Rac1-Pak-Mek-Erk signaling axis. It is also found overexpressed and prognostic in multiple types of cancers.

The aPKCi blocking agent ATM negatively regulates EMT and invasion of HCC.

**Figure 3** ATM partly inhibited transition from epithelial cell markers to mesenchymal cell markers in MMH-RT cells. (a) Cells were treated with 0, 50, and 100 μmol/l ATM, respectively. After 48 h of incubation, cells were harvested and analyzed by western blotting. (b) Expression of EMT markers (E-cadherin, β-catenin, N-cadherin, and vimentin) and aPKC in MMH-RT cells was detected by western blotting (*n* = 3, Student’s *t*-test, mean ± S.D., *P* < 0.05, **P** < 0.01, ImageJ2X software).

**Figure 3** ATM partly inhibited transition from epithelial cell markers to mesenchymal cell markers in MMH-RT cells. (a) Cells were treated with 0, 50, and 100 μmol/l ATM, respectively. After 48 h of incubation, cells were harvested and analyzed by western blotting. (b) Expression of EMT markers (E-cadherin, β-catenin, N-cadherin, and vimentin) and aPKC in MMH-RT cells was detected by western blotting (*n* = 3, Student’s *t*-test, mean ± S.D., *P* < 0.05, **P** < 0.01, ImageJ2X software).

The results showed that the standardized apoptotic rate (%) of mesenchymal MMH-RT cells was dramatically higher than that of epithelial MMH-R cells when concentration of ATM treatment was above 200 μmol/l (Figure 5b, Student’s *t*-test, *P* < 0.05, Supplementary Figure 2), while in MMH-R cells, the apoptosis rate had no obvious correlation with concentration (Figure 5b; Supplementary Figure 2). We also detected the expression of caspase 3, a key molecule of apoptosis signal pathway, in the MMH-R and MMH-RT cells. The results exhibited that the expression of cleaved-caspase 3 of MMH-RT cells was significantly higher than that of MMH-R cells with the increased concentration of ATM (Figure 5c, Student’s *t*-test, *P* < 0.01). These findings indicated that the aPKCi signaling inhibitor could activate the caspase 3-dependent apoptosis pathway and significantly promote the apoptosis of MMH-RT cells.

**Significant inhibition of viability and promotion of apoptosis of HepG2 cell line with aPKCi overexpression by ATM.** Comparison between MMH-D3 and HepG2 cells revealed that HepG2 cells were hepatocarcinoma cells highly expressing aPKCi (Figure 6a, Student’s *t*-test, *P* < 0.01). FACS showed that the apoptotic rate (%) of HepG2 cells was dramatically increased as concentration of ATM was raised up to 50 μmol/l in 48 h (Figures 6b and c, Student’s *t*-test, *P* < 0.05, *P* < 0.01; Supplementary Figure 2). CCK8 assay revealed that HepG2 cells were very sensitive to ATM (Figure 6d). In all, 24, 48, and 72 h after incubation, the IC50 of HepG2 cells was 68.10, 59.93, and 45.59 μmol/l, respectively.
of cancer. Molecular dissection of signaling downstream of aPKC\textsubscript{i} demonstrated that expression of the PB1 domain of aPKC\textsubscript{i} blocks aPKC\textsubscript{i}-dependent Rac1 activity and inhibits cellular transformation, which indicate a role of this domain in the transforming activity of aPKC\textsubscript{i}.\textsuperscript{31} Recently, Alan P Fields reported that the anti-rheumatoid agent ATM is a potent inhibitor of oncogenic aPKC\textsubscript{i} that blocks the formation of aPKC\textsubscript{i}-Par6 complexes by specifically inhibiting PB1 domain-mediated interactions.\textsuperscript{32–34} In the present work, GST pull down and CO-IP were utilized to examine the blocking effect of ATM on aPKC\textsubscript{i}–Par6 binding. The results showed that the breaking of aPKC\textsubscript{i}–Par6 complex by ATM is dose dependent and with increasing concentrations of ATM, the binding of aPKC\textsubscript{i}–Par6 was apparently attenuated \textit{in vitro} and in MMH-RT cells.

Until recently, only few studies on the relationship between EMT and aPKC\textsubscript{i} signaling pathway have been performed. Researchers have focused on the effect of aPKC\textsubscript{i} inhibitor on tumor growth, but ignored the regulatory effects of aPKC\textsubscript{i} on epithelial cell adhesion and cell polarization that are involved in tumor EMT, invasion, and metastasis. Recently, it was reported that TGF-\textbeta treatment increased endogenous aPKC\textsubscript{i} expression in NSCLC cells and aPKC\textsubscript{i} silencing with siRNA reduced TGF-\textbeta-induced EMT.\textsuperscript{35} This study indicated that TGF-\textbeta cooperated with constitutively active v-Ha-Ras to induce and maintain EMT.\textsuperscript{18} This process was accompanied

Figure 4  ATM inhibited viability and invasion of mesenchymal MMH-RT cells. (a–c) At 24, 48, and 72 h of incubation with indicated ATM concentration, the survival rates of MMH-R and MMH-RT cells were detected by CCK8 assay (n = 3, mean ± S.D.). The ATM demonstrated more potent inhibitory effect on mesenchymal MMH-RT cells (squares) than epithelial MMH-R cells (circles). The IC50 of MMH-RT cells was 8528.95 \mu mol/L (24 h), 612.98 \mu mol/L (48 h), and 483.88 \mu mol/L (72 h), respectively. In contrast, the survival rate of epithelial MMH-R cells increased with prolonged treatment of ATM. (d and e) The invasion of MMH-R and MMH-RT cells was detected by transwell assay (×200) at 24 h of incubation with indicated ATM concentration (n = 5, Student’s \textit{t}-test, mean ± S.D., **P < 0.01). ATM inhibited the invasion of both MMH-R cells and MMH-RT cells in a dose-dependent manner in a range of 1–100 \mu mol/L, and 100 \mu mol/L ATM significantly inhibited the invasion of MMH-RT cells than MMH-R cells (n = 5, Student’s \textit{t}-test, mean ± S.D., **P < 0.01).
by loss of cell adhesion, cytoskeletal remodeling, enhanced invasion, and overexpression of aPKC. The results revealed an intimate relationship between the elevated expression of aPKC and the formation and maintenance of EMT. Additionally, ATM not only inhibited the binding between aPKC and Par6 in MMH-RT cells, but also changed their profile of protein expression (from the profile of mesenchymal cells to that of epithelial cells), suppressed the viability and invasion, promoted apoptosis of MMH-RT cells. These findings demonstrated that ATM possesses more potent inhibitory effect on mesenchymal cells than on normal epithelial cells, and aPKC-Par6 signal pathway may cooperate with TGF-β1 to regulate EMT and cell migration in HCC. We also found that, in mesenchymal MMH-RT cells, the expression of aPKC was gradually decreased with ATM concentration, which was different from the findings by Alan P Fields with carcinoma of lungs. The possible explanation might be that there was a negative feedback regulation loop in the downstream of aPKC signal pathway. When aPKC-Par6 complexes were decreased, increased free aPKC and blocked downstream signal transduction would lead to a downregulated expression of aPKC by reactively regulating the translation and the expression.

Although present researches provide a compelling rationale for applying ATM for the clinical treatment of HCC, but the precise mechanism by which ATM inhibits tumors is still unknown. In a study of lung cancer, ATM was used as a highly sensitive PB1-PB1 blocker to inhibit the binding between aPKC and Par6, and was found to uncouple aPKC from the downstream Par6-Rac1 effector pathways. These results provide a plausible unifying molecular mechanism that could account for both the inhibited proliferation and invasion of ATM. The aPKC-Par6 complex functions to activate a Rac1-Mek-Erk signaling axis that drives the transformed growth of NSCLC cells and then activates downstream signaling molecules matrix metalloproteinase 10 (MMP 10), which has an important role in promoting cell invasion. We also found that ATM is a specific inhibitor of PB1 domain-mediated interaction,
and could block aPKC<sub>i</sub>-mediated activation of Rac1 in MMH-RT cells. So, we postulate that ATM might have an inhibitory effect on MMP 10 in hepatoma cells. But the exact mechanism warrants further study.

Previous study demonstrated that the antitumorigenic effects of ATM are mediated through direct inhibition aPKC<sub>i</sub>-Par6-Rac1 pathway of tumor cell proliferation, instead of tumor cell apoptosis or tumor vascularization in NSCLC. Another study showed that ATM induced apoptotic effects through inhibiting not only the aPKC<sub>i</sub>-Par6-Rac1 pathway but also the aPKC<sub>i</sub>-p62-NF-κB pathway in chronic myelogenous leukemia (CML) cells. However, a recent research revealed that ATM sensitivity is positively correlated with expression of aPKC<sub>i</sub> and Par6, but not with that of the aPKC<sub>i</sub>-binding protein p62, or thioredoxin reductase 1 or 2, the proposed targets of ATM in rheumatoid arthritis (RA).

In our study, low concentration ATM remarkably inhibited the expression of aPKC<sub>i</sub> dose-dependently in MMH-RT cells. ATM also could remarkably induce the expression of cleaved-caspase 3 and promote the apoptosis of MMH-RT cells in a dose-dependent manner. On the basis of the previous findings with CML, we were led to postulate that when ATM inhibited the expression of aPKC<sub>i</sub>, it also indirectly decreased the signal transduction efficiency of NF-κB pathway and eliminated the inhibition of apoptosis pathway. The cleaved-caspase 3 was activated and the apoptosis was enhanced. However, involvement of aPKC<sub>i</sub>-P62-NF-κB pathway in aPKC<sub>i</sub>-mediated resistance to apoptosis in HCC still needs further investigation.

In summary, the above results exhibited that aPKC<sub>i</sub> has a pivotal role in EMT. Taken together, our previous findings with HCC tissues and results with EMT cell models in this study, suggested that signal pathway induced by aPKC<sub>i</sub> works with EMT induced by TGF-β1 and Ras interaction, promote invasion and metastasis of carcinoma and resist apoptosis together. aPKC<sub>i</sub> could be regarded as one of the critical bio-markers of HCC EMT, and could be used as an indicator of tumor invasion and malignancy. This research also indicated that ATM exerted, via aPKC<sub>i</sub> signal pathway, powerful and versatile antitumor effects and could regulate EMT process. Although the exact underlying mechanisms remain unclear, the proliferation, apoptosis, and invasion of MMH-RT and HCC cells could be regulated by both blockade of aPKC<sub>i</sub> signal pathway and the secondary decrease in aPKC<sub>i</sub>. These results suggested that ATM has potential to be used for the target therapy of HCC.

Figure 6  ATM significantly inhibited viability of hepatocarcinoma cell line HepG2 and promoted apoptosis of HepG2 cells which has abundant aPKC<sub>i</sub> expression. (a) The difference of aPKC<sub>i</sub> expression in HepG2 and MMH-D3 cells was detected by western blotting (n=3, Student's t-test, mean ± S.D., **P<0.01). (b) At 48-h ATM incubation in a range of 1–600 μmol/l, the apoptotic rates of HepG2 cells were detected by flow cytometry. (c) Following the raised ATM concentration, the standardized apoptotic rates (%) of both HepG2 and MMH-R cells were detected by flow cytometry (n=3, Student's t-test, Mean ± S.D., *P<0.05, **P<0.01). (d) At 24 h (circles), 48 h (squares), 72 h (triangles) of ATM incubation with indicated concentration, the survival rates of HepG2 cells were detected by CCK8 assay (n=3, mean ± S.D.), and the IC50 was 68.10, 59.93, and 45.59 μmol/l, respectively.
Materials and Methods

Cell culture and lentivirus transfection. Immortalized Met murine hepatocytes (MMH-D3) were cultured in RPMI-1640 (Hyclone, Logan, UT, USA) supplemented with 10% fetal bovine serum (FBS; Gibco, Grand Island, NY, USA), 50 ng/ml recombinant human epidermal growth factor (EGF; Peprotech, Rocky Hill, CT, USA), 30 ng/ml recombinant human insulin-like growth factor II (IGF-II; Sigma, St. Louis, MO, USA), 10 μg/ml insulin (Sigma) and 100 U/ml antibiotics. MMH-R cells were established by transfecting lentivirus (PLL3.7 lentivirus vector; Shanghai Gene Chem Co., Ltd, Shanghai, China) to parental MMH-D3 cells with a vector bicistronically expressing constitutive active v-Ha-Ras (amino acids 177–690, GenBank NO: BC006499.2) and GFP. 17 Selection and propagation of a v-Ha-Ras/GFP-positive cell population were performed by subculturing at a ratio of 1:3 twice a week in medium containing growth factors as described for MMH-D3 cells.

Mesenchymal-converted MMH-RT cells were cultured in RPMI-1640 supplemented with 10% FBS, 6–8 ng/ml recombinant human TGF-β1 (Peprotech) and antibiotics. HepG2 cells (obtained from China Center for Type Culture Collection, Wuhan, China) were cultured in DMEM (Hyclone) supplemented with 10% FBS and 100 U/ml antibiotics. All cells were kept at 37 °C in 5% CO2 and routinely screened for the absence of mycoplasma. ATM (Merck, Darmstadt, Germany) was dissolved by purified water and sterile filtration. The different concentrations of ATM were induced with IPTG and determined with SDS-PAGE.

Western blot assay. Cells were washed once with ice-cold phosphate-buffered saline (PBS) and lysed with 0.1–0.2 ml RIPA lysis buffer. The protein concentration was determined by Coomassie protein assay (Pierce, Rockford, IL, USA). Proteins were separated by SDS-polyacrylamide gel electrophoresis (SDS-PAGE) (Bio-Rad, Hercules, CA, USA), and transferred onto a nitrocellulose membrane (Amersham, Chalfont, UK). The membranes were incubated with primary antibodies (aPKC, Santa Cruz Biotechnology, Santa Cruz, CA, USA; E-cadherin, Cell Signaling Technology, Danvers, MA, USA; Par6, Santa Cruz Biotechnology; β-catenin, Cell Signaling Technology; Vimentin, Cell Signaling Technology; N-cadherin, R&D Systems, Minneapolis, MN, USA; v-Ha-Ras, v-Ha-Ras; Santa Cruz Biotechnology; Caspase 3, Santa Cruz Biotechnology) at 4 °C overnight. Peroxidase-conjugated secondary antibodies were applied for 60 min at room temperature at a dilution of 1:2000. β-Actin (Santa Cruz Biotechnology) was used as the internal control. Peroxidase activity was detected by using chemiluminescence method (Amersham) and visualized on X-Omat S films (Amersham).

To quantify the relative levels of protein expression, the intensity of the specific bands was estimated by the ImageJ2X analysis software package (National Institute of Mental Health, Bethesda, MD, USA).

Proliferation assay. In all, 5 × 10^5 cells were cultured in quintuplicate on petri dishes (10 cm in diameter) with medium containing growth factors indicated above. The cells were counted by detaching with trypsin solution and survival cells were counted under a light microscope after trypan blue staining. The assays were repeated at least three times.

Immunofluorescence assay. MMH-R and MMH-RT cells were seeded onto coverslips, incubated overnight and then fixed with 4% paraformaldehyde. Cells were incubated with primary antibodies (E-cadherin, 1:100, Santa Cruz Biotechnology; β-catenin, 1:100, Santa Cruz Biotechnology) for 1 h at room temperature. Cy3-dye-conjugated secondary antibodies (Jackson Laboratories, West Grove, PA, USA) were added for 30 min at room temperature at a dilution of 1:150 in PBS. Cells were then mounted with Mounting Medium containing DAPI (Vector Laboratories, Burlingame, CA, USA). Images were captured by utilizing a Carl Zeiss LSM 710 laser scanning confocal microscope (Carl Zeiss, Oberkochen, Germany).

Plasmid cloning and expression of recombinant proteins. The PB1 domain of human aPKC (amino acids 1–113, GenBank NO: 5584) and Par6a (cDNA, GenBank NO: 50855) was chemically synthesized and separately cloned to prokaryotic expression vectors PET-15b (Novagen, Merck, Germany) and pGEX4T-3 (Amersham Biosciences, GE Healthcare Bio-Sciences, Inc., Pittsburgh, PA, USA) to construct PET-15b/aPKC and pGEX-4T-3/Par6. Genes were sequenced by Invitrogen Co. (Shanghai, China). The recombinant plasmids PET15b/aPKC and pGEX-4T-3/Par6 were transformed into E. coli strain BL21 (DE3). Expression of recombinant protein HIS-aPKC and GST-PAR6 was induced with IPTG and determined with SDS-PAGE.

GUST pull-down assay. Recombinant HIS-aPKC and GST-PAR6 were used as a bait protein to perform GST pull down. For each GST pull-down experiment, 800 μl cell lysate from cells treated with ATM (0, 10, and 50 μM) was added into Handeepin column fixed with GST-PAR6 bait protein and incubated for at least 1 h at 4 °C. The column was washed five times with 400 μl ProFind lysis buffer, incubated for 5 min after mixing in 250 μl glutathione solution (31 mg/ml) and centrifuged at 1250 × g for 30 to 1 min in a collection tube. Eluent was collected and dissolved in a 10% SDS-PAGE gel. The gel was stained with Coomassie blue or applied to immunoblot (rabbit GST antibody, 1:200, ProMab Biotechnologies, Inc., Richmond, CA, USA; rabbit HIS antibody, 1:200, ProMab Biotechnologies, Inc.). The intensity of the specific bands was estimated by employing Gel pro 4.0 software package (Media Cybernetics, Inc., Rockville, MD, USA). The assays were repeated at least three times.

CO-IP assay. MMH-RT cells were cultured with ATM (0, 10, 50, 100, 200, and 400 μM). After 24 h, cells were washed once with ice-cold PBS and lysed in RIPA lysis buffer with 1 mM PMSF. The protein concentration was determined by Coomassie protein assay (Pierce). In 200 μg of cell proteins, rabbit antibody IgG (1:1000) was dropwise added with protein A/G plus-agarose beads (Beyotime Institute of Biotechnology, Haimen, China) 20 μl, and rotated for 2 h at 4 °C to get rid of non-specific combination. The mixture was centrifuged and the supernatant was collected. CO-IP was performed using rabbit anti-aPKC monoclonal antibody (1 μg) or mouse anti-Par6 monoclonal antibody (1 μg) to bind Par6 protein and aPKC protein, respectively. The protein-antibody immunoprecipitates were collected by protein A/G plus-agarose beads. The samples were washed with RIPA buffer five times. Following the final wash, the beads were resuspended in 20 μl of SDS loading buffer. Finally, the samples were boiled and centrifuged to pellet the agarose beads. The supernatant was collected for western blot detection using the Par6 antibody (1:1000) or aPKC antibody (1:500) and proper second antibody. The intensity of the specific bands was estimated by Image J2X software package. The assays were repeated at least three times.

Viability assay. Cell viability was colorimetrically assessed using the CCK8 (1:10, Dojing Laboratories Co., Ltd., Kumamoto, Japan). Cells were seeded into 96-well plates at a density of 5 × 10^3 cells/well in 200 μl culture medium. In all, 24, 48, and 72 h after the culture, the medium was removed by aspiration and replaced with 100 μl of experimental medium. In all, 10 μl CCK8 solution was added to each well and the plates were incubated for 1–4 h at 37 °C. Absorbance was recorded at 450 nm using the μQuant ELISA Reader (Bio Tek Instruments, Inc., Winooski, VT, USA). The percentage of survival rate was calculated according to the following formula: survival rate (%treated) = (ODtreated−ODblank)/(ODcontrol−ODblank) × 100%, IC50 was calculated using probit regression analysis. The assays were conducted in triplicate and repeated at least three times.

Cell invasion. Cells invasion was detected using transwell assay (8 μm pore size; Coming Costar Corp, Coming Incorporated, Coming, NY, USA). The transwell inserts were put into the 24-well plates and coated with Matrigel (BD Biosciences, Franklin Lakes, NJ, USA). Freshly trypsinized and washed cells were suspended in 200 μl of RPMI-1640 containing 1% FBS. In all, 1 × 10^4 cells/well was placed in the top chamber of each insert and 600 μl of RPMI-1640 containing 10% FBS was added into the lower chambers. After incubation for 24 h at 37 °C in a 5% CO2 humidified incubator, cells were fixed with 95% absolute alcohol and stained with crystal violet. The cells in the inner chamber were removed with a cotton swab and cells attached to the bottom side of the membrane were counted and imaged under an Olympus BX-41 microscope (Olympus) at ×200 magnification over four random fields in each well. Each experiment was performed in triplicate.

Flow cytometry. Cells were seeded onto 12-well plates at a cell density of 1 × 10^5 cells/well in 1.5 ml of culture medium and allowed to adhere overnight. Twenty-four hours after the culture, the medium was removed by aspiration and replaced with 1.5 ml of experimental medium containing 0, 1, 10, 200, 400, and 600 μmol ATM. Forty-eight hours after the incubation, the cells were harvested and apoptosis was flow cytometrically determined by using Annexin V-PE/7-AAD and Annexin V-FITC/PI apoptosis detection kit (KeyGen Biotechnology Co., Ltd, Nanjing, China) according to the manufacturer's instructions. The standardization of apoptosis rate was calculated according to the following formula: standardized apoptosis rate (%) = apoptosis rate (%)treated − apoptosis rate (%)control. All experiments were conducted at least three times with similar results.

The aPKC blocking agent ATM negatively regulates EMT and invasion of HCC

CQ Ma et al
Statistical analysis. Data were statistically analyzed by using the software package SPSS (version 19.0) for Windows supplied by the Statistics Teaching Room of Tongji Medical College, Huazhong University of Science and Technology. Statistical significance was assessed by means of Student’s t-test. Results were presented as mean ± standard deviation (S.D.) unless otherwise stated and difference was considered to be significant when \( *P < 0.05 \) and \( **P < 0.01 \).

Conflict of Interest
The authors declare no conflict of interest.

Acknowledgements. We were indebted to Professor Marco Tripodi (Università La Sapienza, Italy) who provided MMH-D3 cells and valuable suggestions in the preparation of the manuscript.
