A quantum steganography protocol with a large payload is proposed based on the dense coding and the entanglement swapping of the Greenberger–Horne–Zeilinger (GHZ) states. Its super quantum channel is formed by building up a hidden channel within the original quantum secure direct communication (QSDC) scheme. Based on the original QSDC, secret messages are transmitted by integrating the dense coding and the entanglement swapping of the GHZ states. The capacity of the super quantum channel achieves six bits per round covert communication, much higher than the previous quantum steganography protocols. Its imperceptibility is good, since the information and the secret messages can be regarded to be random or pseudo-random. Moreover, its security is proved to be reliable.

Keywords: quantum steganography, quantum secure direct communication, dense coding, entanglement swapping

1. Introduction

Quantum secure communication can transmit secret messages with unconditional security by using the law of quantum mechanics, and can be classified into quantum key distribution (QKD)\[1–4\], quantum secure direct communication (QSDC)\[5–14\], quantum secret sharing (QSS)\[15–18\], and so on. The goal of QKD is to establish a shared secret key between two remote authorized users. In 1984, Bennett and Brassard\[9\] proposed the famous BB84 protocol, which is the first QKD protocol. Afterward, a lot of QKD schemes have been put forward.\[2–4\] The QSDC allows secret messages to be transmitted directly without creating a key to encrypt them in advance. The main protocols proposed are summarized as follows. In 2002, Beige et al.\[5\] put forward the first QSDC protocol. In the same year, Bostrom and Felbinger\[6\] suggested the famous ping–pong protocol. In 2003, Deng et al.\[7\] presented a two-step QSDC based on the Bell states. In 2004, Cai and Li\[8\] introduced two additional unitary operations to improve the capacity of the ping–pong protocol. In 2005, Wang et al.\[9\] put forward a multi-step QSDC using the multi-particle Greenberger–Horne–Zeilinger (GHZ) state, and Gao et al.\[10\] put forward a simultaneous QSDC between the central party and other M parties. In 2008, Sun et al.\[11\] proposed a new multiparty simultaneous QSDC based on GHZ states and dense coding; Chen et al.\[12\] proposed a novel controlled QSDC protocol with quantum encryption using a partially entangled GHZ state; Chen et al.\[13\] proposed a novel three-party controlled QSDC protocol based on the W state. In 2012, Huang et al.\[14\] proposed two robust channel-encrypting QSDC protocols over different collective-noise channels. As the quantum counterpart of the classical secret sharing, the QSS allows that neither individual agent is able to obtain the secret messages sent by the dealer unless they cooperate. In 1999, Hillery et al.\[15\] put forward the first QSS protocol with the GHZ state. In 2003, Guo et al.\[16\] presented a QSS protocol only using product states. In 2012, Chen et al.\[17\] put forward an improved multiparty QSS based on the GHZ state to resist attacks from both outside attackers and inside participants. In 2013, Chen et al.\[18\] put forward a three-party QSS protocol via the entangled GHZ state using a single-particle quantum state to encode the information.

Classical steganography inserts secret messages into an innocent cover object to hide the existence of secret messages. In recent years, the concept of quantum steganography has been put forward, which extends the concept of the classical steganography into the quantum scenario. Different from traditional quantum secure communication, quantum steganography always builds up another hidden channel within the normal quantum channel to transmit secret messages. That is, quantum steganography uses the hidden channel to hide the secret messages into the normal quantum channel. In 2002, Gea-Banacloche\[19\] used the quantum error-correcting code to encode quantum data and hid secret messages as errors. In 2004, Worley\[20\] suggested a fuzzy quantum watermarking protocol with the relative frequency of error from observing qubits. In 2007, based on the BB84 QKD scheme,\[11\]
Martín[21] presented a novel quantum steganography protocol. In 2010, based on Guo et al.’s QSS scheme,[16] Liao et al.[22] proposed a novel multi-party quantum steganography protocol. In 2010, based on an improved ping–pong scheme (IBF),[8] Qu et al.[23] suggested a novel quantum steganography scheme with a large payload. However, the capacity of the quantum channels in Refs. [19]–[22] is only one bit or one qubit per round covert communication, which is apparent too small for efficient covert communication. Although the capacity in Ref. [23] has been increased to four bits, it is still not large enough.

Based on the above analysis, for improving quantum channel’s capacity, we propose a novel quantum steganography protocol with a large payload based on the dense coding and the entanglement swapping of the GHZ states. Its super quantum channel is formed by building up the hidden channel within the original QSDC. Based on the original QSDC, secret messages are transmitted by integrating the dense coding and the entanglement swapping of the GHZ states. It can transmit six bits per round covert communication, six times of that in Refs. [19]–[22] and one and half times of that in Ref. [23]. Since the information and secret messages can be regarded to be random or pseudo-random, its imperceptibility is good. Moreover, its security is proved to be reliable.

2. Coding scheme

The dense coding of the GHZ states is briefly introduced first. The dense coding of the GHZ states, proposed by Lee et al.,[24] is the generalization of the dense coding scheme of Bennett and Wiesner[25] The GHZ states are three-particle maximally entangled states, and form a complete orthogonal basis of 8-dimensional Hilbert space. The eight independent GHZ states are

\[ |\Psi_1\rangle = \frac{1}{\sqrt{2}} \left( |000\rangle + |111\rangle \right), \quad |\Psi_2\rangle = \frac{1}{\sqrt{2}} \left( |000\rangle - |111\rangle \right), \]
\[ |\Psi_3\rangle = \frac{1}{\sqrt{2}} \left( |100\rangle + |011\rangle \right), \quad |\Psi_4\rangle = \frac{1}{\sqrt{2}} \left( |100\rangle - |011\rangle \right), \]
\[ |\Psi_5\rangle = \frac{1}{\sqrt{2}} \left( |010\rangle + |101\rangle \right), \quad |\Psi_6\rangle = \frac{1}{\sqrt{2}} \left( |010\rangle - |101\rangle \right), \]
\[ |\Psi_7\rangle = \frac{1}{\sqrt{2}} \left( |110\rangle + |001\rangle \right), \quad |\Psi_8\rangle = \frac{1}{\sqrt{2}} \left( |110\rangle - |001\rangle \right). \]

By performing single-particle unitary operations on any two of the three particles, one GHZ state can be transformed into another GHZ state, where four single-particle unitary operations are

\[ I = |0\rangle \langle 0| + |1\rangle \langle 1|, \quad \sigma_z = |0\rangle \langle 0| - |1\rangle \langle 1|, \]
\[ \sigma_x = |0\rangle \langle 1| + |1\rangle \langle 0|, \quad i\sigma_y = |0\rangle \langle 1| - |1\rangle \langle 0|. \]

Without loss of generality, |\Psi_1\rangle is assumed as the initial state. Accordingly, |\Psi_1\rangle can be transformed into |\Psi_k\rangle (k = 1, 2, \ldots, 8) by performing \( U_k \) on its first and second particles, namely,

\[ U_k |\Psi_1\rangle = |\Psi_k\rangle, \quad (k = 1, 2, \ldots, 8), \]

where

\[ U_1 = \sigma_z \otimes \sigma_z, \quad U_2 = I \otimes \sigma_z, \quad U_3 = i\sigma_y \otimes \sigma_z, \]
\[ U_4 = \sigma_z \otimes \sigma_z, \quad U_5 = I \otimes \sigma_z, \quad U_6 = \sigma_z \otimes \sigma_z, \]
\[ U_7 = \sigma_z \otimes \sigma_z, \quad U_8 = i\sigma_y \otimes \sigma_z. \]

Let each \( U_k \) correspond to three bits information, namely,

\[ U_1 \rightarrow 000, \quad U_2 \rightarrow 001, \quad U_3 \rightarrow 010, \quad U_4 \rightarrow 011, \]
\[ U_5 \rightarrow 100, \quad U_6 \rightarrow 101, \quad U_7 \rightarrow 110, \quad U_8 \rightarrow 111. \]

Based on the above description, after the dense coding of the GHZ states, one GHZ state can transmit three bits information.

The results of entanglement swapping between |\Psi_1\rangle and arbitrary one of the eight GHZ states are shown as follows:

\[ |\Psi_1\rangle_{A_1B_1C_1} \otimes |\Psi_4\rangle_{A_2B_2C_2} = \left( \frac{1}{\sqrt{2}} \right)^3 \left( |\Phi^+\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2} \right. \]
\[ + |\Phi^-\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2} \]
\[ + |\Phi^-\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} \]
\[ + |\Phi^+\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} \]
\[ + |\Phi^-\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2} \]
\[ + |\Phi^+\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} \]
\[ + |\Phi^-\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} \), \]

\[ |\Psi_4\rangle_{A_1B_1C_1} \otimes |\Psi_2\rangle_{A_2B_2C_2} = \left( \frac{1}{\sqrt{2}} \right)^3 \left( |\Phi^+\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} \right. \]
\[ + |\Phi^-\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2} \]
\[ + |\Phi^-\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} \]
\[ + |\Phi^+\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2} \]
\[ + |\Phi^-\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} \]
\[ + |\Phi^+\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} \]
\[ + |\Phi^-\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} \), \]

\[ |\Psi_4\rangle_{A_1B_1C_1} \otimes |\Psi_3\rangle_{A_2B_2C_2} = \left( \frac{1}{\sqrt{2}} \right)^3 \left( |\Phi^+\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} \right. \]
\[ + |\Phi^-\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} \]
\[ + |\Phi^-\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} \]
\[ + |\Phi^+\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2} \]
\[ + |\Phi^-\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2} \]
\[ + |\Phi^+\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2} \]
\[ + |\Phi^-\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2} \)]. \]
\[ + |\Phi^+\rangle_{A_1A_2} |\Psi^-\rangle_{B_1B_2} |\Psi^+\rangle_{C_1C_2}, \] (8)

\[ = \left( \frac{1}{\sqrt{2}} \right)^3 \left( |\Psi^+\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2} + |\Psi^-\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} + |\Psi^-\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2} + |\Psi^+\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} + |\Psi^+\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} + |\Psi^-\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2} + |\Psi^-\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2} + |\Psi^+\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2} \right), \] (9)

where subscripts \(A_i, B_i, \) and \(C_i (i = 1, 2)\) denote three particles in the GHZ states, respectively.

According to formulas (6)–(13), each result of \(A_1A_2, B_1B_2,\) and \(C_1C_2\) after the entanglement swapping does only correspond to one initial state among the above eight known initial states. Corresponding to formulas (6)–(13), eight collections composed by different results of \(A_1A_2, B_1B_2,\) and \(C_1C_2\) after the entanglement swapping are coded as follows:

\[ \{ |\Phi^+\rangle_{A_1A_2} |\Phi^-\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2}, \] (14)
\[ |\Phi^+\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^-\rangle_{C_1C_2}, \] (15)
\[ |\Phi^-\rangle_{A_1A_2} |\Phi^+\rangle_{B_1B_2} |\Phi^+\rangle_{C_1C_2}, \] (16)
and all particles are eventually transmitted from one com-

munication party to the other communication party. However,

in that original QSDC, the third particle from each GHZ triplet

is always kept intact in one communication party’s hand, while

the first and the second particles are transmitted between

the two communication parties. The basic idea of the original

QSDC is as follows. (i) Bob keeps the sequence of the third

particle from each GHZ triplet in hand, and sends the se-

matical states $|\Psi\rangle_8$ and $|\Phi\rangle_8$, and the initial

state of the particles $A_1, B_1, C_1$ to be $|\Psi_800\rangle_{A_1B_1C_1}$

and the initial state of the particles $A_2, B_2, C_2$ to be $|\Psi_8101\rangle_{A_2B_2C_2}$ for example. The superscript in $|\Psi_800\rangle_{A_1B_1C_1}$ denotes that $|\Psi_800\rangle_{A_1B_1C_1}$ can be obtained by performing $U_2$ on the first and the second particles of $|\Psi_800\rangle_{A_1B_1C_1}$, while 100 denotes that the result collection composed by $A_1A_2, B_1B_2,$ and $C_1C_2$ after the entanglement swapping from $|\Psi_800\rangle_{A_1B_1C_1}$ and $|\Psi_8101\rangle_{A_2B_2C_2}$ corresponds to formula (18).

3. Quantum steganography protocol

Our quantum steganography protocol integrates the origi-
nal QSDC adopting the dense coding of the GHZ states, which
is inspired by Refs. [7] and [9], and the entanglement swap-
ning of the GHZ states together. In the schemes of Refs. [7]
and [9], all particles are eventually transmitted from one com-
munication party to the other communication party. However,
in that original QSDC, the third particle from each GHZ triplet
is always kept intact in one communication party’s hand, while
the first and the second particles are transmitted between
the two communication parties. The basic idea of the original
QSDC is as follows. (i) Bob keeps the sequence of the third
particle from each GHZ triplet in hand, and sends the se-
quences of the first and the second particles to Alice one by one. In order to ensure security, the eavesdropper detection is implemented in each transmission. (ii) According to the bits sequence of information, Alice then adopts the dense coding of the GHZ states to perform unitary operations on the two sequences. Afterward, Alice sends the two encoded sequences back to Bob. (iii) Finally, Bob implements the GHZ-basis measurement on each GHZ triplet to recover the information. Due to the dense coding of the GHZ states, the original QSDC can transmit three bits information per round communication. Now, we demonstrate our quantum steganography protocol in detail as follows.

S1) Bob prepares a large number \( n \) of \(|\Psi_{1}\rangle_{ABC}\). Let \( G_A, G_B, \) and \( G_C \) denote the particle groups of A, B, and C, respectively. Accordingly, \( G_A = [A_1, A_2, \ldots, A_n] \), \( G_B = [B_1, B_2, \ldots, B_n] \), and \( G_C = [C_1, C_2, \ldots, C_n] \), where the subscript denotes the number of GHZ states.

S2) Bob sends \( G_A \) and \( G_B \) to Alice by a quantum channel in two steps. (i) Bob sends \( G_A \) to Alice while keeping \( G_B \) and \( G_C \) to himself. For eavesdropper detection, Alice selects a large enough subgroup from \( G_A \), and chooses randomly a measurement basis, Z-basis \((|0\rangle, |1\rangle)\) or X-basis \((|+\rangle, |−\rangle)\), to measure particle A in the subgroup from \( G_A \). Alice publishes her measurement basis and measurement results to Bob. After obtaining Alice’s results, Bob measures particle B from the corresponding subgroup of \( G_B \) and particle C from the corresponding subgroup of \( G_C \) under the same measurement basis. According to formula (22), by comparing with Alice’s measurement results, Bob can know whether there is an eavesdropper or not. If the channel is safe, their measurement results are highly correlated. Then, if Bob confirms that there is an eavesdropper, they abort the communication; otherwise, they enter the following step (ii). (ii) Bob sends \( G_C \) to Alice by a quantum channel over, through the decoded secret messages and the state of \( \Psi_{1} \) to perform unitary operations on the particle in \( G_C \), for consistence, \( G_C \) is still used to represent the original \( G_C \). Accordingly, \( G_C \) is the same as \( G_A \). (iii) According to secret messages, Alice chooses four particles \( A_{m_1} \), \( A_{m_1+1} \), \( B_{m_1} \), \( B_{m_1+1} \) from \( G_A \) and \( G_B \), respectively, and enters the secret message hiding mode. (iii) Alice sends \( G_A \) and \( G_B \) back to Bob by a quantum channel.

S3) Information transmission mode (i) According to the bits sequence of information, Alice performs \( U_k \) on the pairs of particles in \( G_A \) and \( G_B \). Note that after performed with \( U_k \), \( G_A \) and \( G_B \) become \( G_A' \) and \( G_B' \), respectively. Although no unitary operations have been performed on the particle in \( G_C \), for consistence, \( G_C' \) is still used to represent the original \( G_C \). Accordingly, \( G_C' \) is the same as \( G_A' \). (ii) According to secret messages, Alice chooses four particles \( A_{m_1}' \), \( A_{m_1+1}' \), \( B_{m_1}' \), \( B_{m_1+1}' \) from \( G_A' \) and \( G_B' \), respectively, and enters the secret message hiding mode. (iii) Alice sends \( G_A' \) and \( G_B' \) back to Bob by a quantum channel.

S4) Secret message hiding mode (i) According to secret messages, Alice chooses four particles \( A_{m_1}' \), \( A_{m_1+1}' \), \( B_{m_1}' \), \( B_{m_1+1}' \) from \( G_A' \) and \( G_B' \), respectively, where subscript \( m \) represents the position of particle \( A_{m_1}' \) in \( G_A' \) and the position of particle \( B_{m_1}' \) in \( G_B' \). The \( m \) must satisfy the consistent condition, which means two GHZ states formed by \( A_{m_1}'B_{m_1}'C_{m_1}' \) and \( A_{m_1}'B_{m_1}'C_{m_1}' \) must be consistent with the secret messages, as shown in Table 1 (an appropriate \( m \) can be decided by Alice in advance before sending it to Bob by implementing QSDC, QKD, or a one-time pad through the classical channel [23]). (ii) By performing the same \( U_k \) on \( A_{m_1+1}' \) and \( B_{m_1+1}' \) in advance, \( A_{m_1}'B_{m_1}'C_{m_1}' \) can copy the information carried by \( A_{m_1-1}'B_{m_1}'C_{m_1}' \). Consequently, \( A_{m_1}'B_{m_1}'C_{m_1}' \) does not normally transmit information but acts as an auxiliary GHZ state to help hide the secret messages.

S5) Secret message decoding mode (i) Bob gets the value of \( m \). (ii) Bob performs the GHZ-basis measurement on \( A_{m_1-1}'B_{m_1-1}'C_{m_1}' \) to recover the information. (iii) Bob performs the Bell-basis measurement on \( A_{m_1}'A_{m_1+1}' \), \( B_{m_1}'B_{m_1+1}' \), and \( C_{m_1}'C_{m_1+1}' \) respectively. (iv) Then, Bob decodes the secret messages sent by Alice according to formulas (14)-(21). Moreover, through the decoded secret messages and the state of \( A_{m_1-1}'B_{m_1-1}'C_{m_1}' \), Bob can also recover the information carried by \( A_{m_1}'B_{m_1}'C_{m_1}' \) according to Table 1.

We use an example to further explain secret message hiding mode S4) and secret message decoding S5) in our quantum steganography protocol. Assume that the secret messages Alice wants to send to Bob are 100, and the information sequence \( \ldots 000100 \ldots 001000 \ldots 101000 \cdots 110010 \cdots 011111 \cdots 100000 \cdots 101001 \ldots 110101 \cdots 111011 \cdots \) is generated.

\[
|\Psi_{1}\rangle_{ABC} = \frac{1}{\sqrt{2}} \left( |000\rangle_{ABC} + |111\rangle_{ABC} \right)
= \frac{1}{2} \left( |+\rangle_{A} |+\rangle_{B} |+\rangle_{C} + |−\rangle_{B} |−\rangle_{C} \right)
+ |−\rangle_{A} |+\rangle_{B} |−\rangle_{C} + |+\rangle_{B} |+\rangle_{C} \right)
= \frac{1}{2} \left( (|+\rangle_{A} |+\rangle_{B} + |−\rangle_{A} |−\rangle_{B}) |+\rangle_{C}
+ (|−\rangle_{A} |+\rangle_{B} + |−\rangle_{A} |+\rangle_{B}) |−\rangle_{C} \right).
\]
by Alice (the information is divided by six bits, since two \( U_k \) denote six bits information). Assume that the group numbers of 000, 01100, 01010, 01111, 10000, 10100, 110010, and 11110 in the information sequence are Nos. 7, 10, 13, 16, 20, 25, 28, and 32, respectively. In S3), Alice can make \( m = 7 \), 10, 13, 16, 20, 25, 28, or 32 to satisfy the consistency in Table 1. If \( m = 7 \), \( A_0' B_6' C_6' \) will be \( |\Psi_1^{+}\rangle \) and \( A_0' B_7' C_7' \) will be \( |\Psi_5^{+}\rangle \).

Accordingly, the secret messages 100 are transmitted by the entanglement swapping between \( A_0' B_7' C_7' \) and \( A_0' B_6' C_6' \). The secret messages 100 can also be transmitted in the same way, if \( m = 10, 13, 16, 20, 25, 28, \) or 32. Note that \( A_m' B_8' C_8' \) cannot be used to transmit the information like the other normal GHZ states, and acts as an auxiliary GHZ state to help hide the secret messages. In S6), Bob obtains the value of \( m \) at first. Afterward, Bob performs the GHZ-basis measurement on \( A_m' B_6' C_6' \). Then, Bob performs the Bell-basis measurement on \( A_7' A_0' B_7' B_6' \), and \( C_7' C_6' \) respectively. According to formulas (14)–(21), Bob can decode that the secret messages are 100. Then, according to the state of \( A_7' B_7' C_7' \) (\( |\Psi_1^{+}\rangle \)), the secret messages 100, and Table 1, Bob can easily know that the information carried by \( A_7' B_7' C_7' \) is 100.

4. Analysis

4.1. Capacity

In the above quantum steganography protocol, three bits secret messages are transmitted by the entanglement swapping between \( A_{m+1}' B_{m+1}' C_{m+1}' \) and \( A_m' B_m' C_m' \). In addition, \( A_{m+1}' B_{m+1}' C_{m+1}' \) copies the information carried by \( A_m' B_m' C_m' \) and acts as an auxiliary GHZ state to help hide the secret messages. Accordingly, the information carried by \( A_{m+1}' B_{m+1}' C_{m+1}' \) is recovered, while \( A_m' B_m' C_m' \) is consumed. Moreover, it is clear that three bits secret messages can be transmitted by eight different kinds of initial states. For example, according to Table 1, messages 100 can be transmitted by eight different kinds of initial states

\[
\begin{align*}
|\Psi_1^{+}\rangle_{A_1 B_1 C_1}, & \quad |\Psi_2^{+}\rangle_{A_2 B_2 C_2}, \\
|\Psi_3^{+}\rangle_{A_3 B_3 C_3}, & \quad |\Psi_4^{+}\rangle_{A_4 B_4 C_4}, \\
|\Psi_5^{+}\rangle_{A_5 B_5 C_5}, & \quad |\Psi_6^{+}\rangle_{A_6 B_6 C_6}, \\
|\Psi_7^{+}\rangle_{A_7 B_7 C_7}, & \quad |\Psi_8^{+}\rangle_{A_8 B_8 C_8},
\end{align*}
\]

After coding these eight different kinds of initial states by formula (23), the capacity of the quantum channel in the above quantum steganography protocol can be increased to six bits. Consequently, the quantum channel capacity is six times of that in Refs. [19]–[22], and one and half times of that in Ref. [23]. The reason why the quantum channel capacity is larger than that in Ref. [23] lies in two facts. (i) The entanglement swapping between two GHZ states transmits three bits in our quantum steganography protocol, while the entanglement swapping between two Bell states only transmits two bits in Ref. [23]. (ii) Each three bits secret message corresponds to eight different kinds of initial states in our quantum steganography protocol, while each two bit secret message corresponds to four different kinds of initial states in Ref. [23].

Based on the above analysis, our quantum steganography protocol can transmit six bits per round covert communication. In fact, our quantum steganography protocol transmits secret messages by building up a hidden channel within the original QSDC. However, the original QSDC only transmits three bits per round covert communication. Thus, the transmission efficiency of our quantum steganography protocol is twice of that of the original QSDC. It can be concluded that the super quantum channel integrating the original quantum channel of the QSDC and the hidden channel in our quantum steganography protocol can enlarge the capacity of the quantum channel. It is also possible to apply the idea of our quantum steganography protocol to QSS and QKD based on the GHZ states to enlarge the transmission efficiency of the original quantum channel.

4.2. Imperceptibility

In our quantum steganography protocol, the choice of \( m \) is not arbitrary for Alice, since the value of \( m \) must satisfy the consistent condition with respect to \( A_{m-1}' B_{m-1}' C_{m-1}' \), \( A_m' B_m' C_m' \), and secret messages. Consequently, the imperceptibility mainly depends on the difficulty of knowing \( m \) by Eve. As pointed out in Ref. [23], choosing \( m \) can still be treated as an arbitrary behavior for Eve, since both information and secret messages can be regarded to be random or pseudo-random. If the information or secret messages do not distribute randomly in advance, a pseudo-random sequence encryption can be adopted to make its distribution randomized.

For example, if the secret messages Alice wants to send to Bob are 100, in order to choose \( m \), Alice needs to find out all the group numbers of 000, 00100, 001101, 010010, 011111, 100000, 101010, 110011, 111101, 000110, 011010, 111011 in the information sequence. Accordingly, the GHZ states \( A_m' B_m' C_m' \) and \( A_m' B_m' C_m' \) will be \( |\Psi_1\rangle, |\Psi_2\rangle, |\Psi_3\rangle, |\Psi_4\rangle, |\Psi_5\rangle, |\Psi_6\rangle, |\Psi_7\rangle, |\Psi_8\rangle \), and \( |\Psi_9\rangle, |\Psi_{10}\rangle, |\Psi_{11}\rangle, |\Psi_{12}\rangle \) respectively. If the information distributes evenly, probability of 000, 001, 010, 011, 100, 101, 110, 111 will be 1/6 each. Consequently, their total probability is 1/8. It is similar if the secret messages are 000, 001, 010, 011, 101, 110, or 111. Therefore,
the probability distributions of information and secret messages will make $m$’s uncertainty best according to Shannon’s information theory, as pointed out in Ref. [23]. Consequently, $m$ can be regarded as a random number for Eve. It means that the imperceptibility of our quantum steganography protocol is good.

4.3. Security

The security of our protocol can be proved via the security of the original QSDC. The original QSDC uses the GHZ states, and its security is similar to the scheme using the Bell states in Ref. [7]. The security of the original QSDC is based on the security for the transmission of $G_A$ and $G_B$ from Bob to Alice.

Now we analyze the security for the transmission of $G_A$ against the entanglement-and-measurement attack at first. According to the Stinespring dilation theorem, Eve’s eavesdropping can be realized by a unitary operation $\hat E$ on a larger Hilbert space, $|x, E\rangle \equiv |x\rangle |E\rangle$. Therefore, the state of the composite system will be

$$|\psi\rangle = \frac{1}{\sqrt{2}}\left[ (1 - |\beta_1|^2) |\beta_1\rangle |\beta_1\rangle |\epsilon_{01}\rangle |00\rangle + (|\beta_1|^2 - 1 + |\alpha_1|^2) |\alpha_1\rangle |\beta_1\rangle |\epsilon_{11}\rangle |11\rangle \right],$$

(24)

where $\epsilon_{00}, \epsilon_{01}, \epsilon_{10}, \epsilon_{11}$ are Eve’s states, and $\hat E = \left( \begin{array}{cc} \alpha_1 & \beta_1 \\ \bar{\beta}_1 & \bar{\alpha}_1 \end{array} \right)$ is Eve’s probe operator. Since $\hat E$ is a unitary operator, we can obtain that the error rate introduced by Eve’s eavesdropping on $G_A$ is $\tau_1 = |\beta_1|^2 = |\beta_1'|^2 = 1 - |\alpha_1|^2 = 1 - |\alpha_1'|^2$. The security for the transmission of $G_B$ against the entanglement-and-measurement attack can be analyzed in a similar way as above. After Eve eavesdrops $G_B$ before the second checking, the state of the composite system will be

$$|\psi\rangle = \frac{1}{\sqrt{2}}\left[ |0\rangle \left( |\alpha_2\rangle |\epsilon_{00}\rangle + |\beta_2\rangle |\epsilon_{01}\rangle \right) |00\rangle + |1\rangle \left( |\beta_2\rangle |\epsilon_{10}\rangle + |\alpha_2\rangle |\epsilon_{11}\rangle \right) |11\rangle \right].$$

(25)

We can obtain that the error rate introduced by Eve’s eavesdropping on $G_B$ will be $\tau_2 = |\beta_2|^2 = |\beta_2'|^2 = 1 - |\alpha_2|^2 = 1 - |\alpha_2'|^2$.

Without loss of generality, we turn to analyze the measure-resend attack on $G_A$. Eve intercepts particle $A$ in $G_A$, measures it in $Z$-basis or $X$-basis, and resends its measurement result to Alice. If Eve performs the $Z$-basis measurement, the state of the whole system will collapse to $|000\rangle$ or $|111\rangle$ each with probability $1/2$. Take the state to be $|000\rangle_{ABC}$ for example. Accordingly, Eve resends $|0\rangle_A$ to Alice. Then, if Alice performs the $Z$-basis measurement to check eavesdropping, no error will be introduced by Eve. If Alice performs the $X$-basis measurement, the state will collapse to $|opq\rangle_{ABC}$ ($o, p, q = +, -$) each with probability $1/8$. According to formula (22), the error rate introduced by Eve will be $50\%$. Therefore, the total error rate in this case is $25\%$. If Eve uses $X$-basis, the total error rate in this case is $37.5\%$. Therefore, the random $Z$-basis or $X$-basis measurement guarantees that Eve’s attack can be found out by eavesdropping check.

Further, we consider the influence caused by the leakage of $m$. Assume that Eve not only obtains $m$ but also gets $A'_mA'_{m+1}$ and $B'_mB'_{m+1}$ through some advance eavesdropping attacks (it is possible for Eve to eavesdrop $A'_mA'_{m+1}$ and $B'_mB'_{m+1}$, since particles $A$ and $B$ are travel particles). However, Eve still cannot get secret messages according to formulas (14)–(21), because only knowing $A'_mA'_{m+1}$ and $B'_mB'_{m+1}$ is not enough to decode the secret messages.

5. Discussion and conclusion

As analyzed in Subsection 4.1, the capacity of the super quantum channel in our quantum steganography protocol achieves six bits, and is twice of that of the original QSDC. The reason lies in that the super quantum channel is formed by building up a hidden channel within the original QSDC. However, the hidden channel works at the cost of transmitting $m$. Transmitting $m$ means to transmit log$_2 m$ bits. If $m$ is great enough, transmitting $m$ may consume more bits than the secret messages. Fortunately, as pointed out in Ref. [23], since $m$ can be decided and transmitted by implementing QSDC, QKD, or a one-time pad through the classical channel in advance, it is unnecessary to overemphasize the cost of transmitting $m$. Furthermore, since $m$ and the secret messages tend to have different security levels, it is reasonable to consume a certain resource to achieve the covert communication for secret messages.

To sum up, a quantum steganography protocol with a large payload is proposed based on the dense coding and the entanglement swapping of the GHZ states. Its super quantum channel is formed by building up a hidden channel within the original QSDC. Based on the original QSDC, secret messages are transmitted by integrating the dense coding and the entanglement swapping of the GHZ states. It can transmit six bits per round covert communication, much higher than the previous quantum steganography protocols. Since the information and the secret messages can be regarded to be random or pseudo-random, its imperceptibility is good. Moreover, its security is proved to be reliable. In the future, our research of quantum steganography will concentrate on two aspects, i.e., using quantum error-correcting code to hide secret messages and applying quantum Fourier transform into the literature of steganography.
