ABSTRACT
In this work, binary mixtures of a non-ionic surfactant (Triton X-100) and water were studied with concentrations of 30%wt H 2O, showing, lamellar mesophase at temperatures below 10°C. Different dicationic ionic liquids were used for doping these mesophases: 1,n-bis(3-methylimidazolium-1-yl)alkane, 1,n-bis(1-methylpyrrolidinium-1-yl)alkane and 1,n-bis(pyridinium-N-yl)alkane dibromide, where n = 6 and 8. Polarized Optical Microscopy and Small-Angle X-ray Scattering were used for identifying the mesophases and the influence of different dicationic ionic liquids on the lyotropic liquid crystals phase transitions. The addition of dicationic ionic liquids to the lyotropic liquid crystals samples led to changes in transition temperature and in mesophase structure itself (such as characteristic distances).

Introduction
Triton-X 100/water binary system has a well-known phase diagram [1] in which the main ordered phase is hexagonal, and also have a small region of lamellar phase at low temperature (from 0°C to 6°C) and high concentrations (from 65 to 80 wt% of Triton X-100).

Ionic liquids (ILs) are salts with low melting points (<100°C), solely composed of mobile ions. They are often referred to as designer materials due to the infinite possibility of combinations for anions and cations, thus rendering ionic liquids with their own set of physical or chemical properties, suitable for specific applications in several fields, such as electrochemistry [2], catalysis [3], [4], [5], [6], [7], CO 2 absorption [8] and gas chromatography stationary phases [9], among others.

Ionic liquid crystals are a class of liquid-crystalline compounds that contain ionic units in the mesophase. Due to the presence of anions and cations, ionic liquid crystals are ion conductive, enabling the construction of materials with anisotropic electric current conductivity [10]. In general, ionic interactions tend to stabilise lamellar mesophases, due to an ion-ion stacking and electrostatic interactions [11].

Exploration of the lyotropic liquid crystals (LLC) behaviours of surfactants in ionic liquids may provide a better understanding of intermolecular actions in self-assembly and also improve some properties of LLC, like better thermostability compared to those constructed in...
aqueous media. In these systems, various LLC phases could be detected, including the normal hexagonal, lamellar, sponge and reverse bicontinuous cubic phases, some of them not detected in aqueous media. The modification of the alkyl chain length in surfactant was reported as a possible way to come from a reversal to a normal mesophase [12].

The introduction of self-assembled nanostructures into IL systems is an efficient way to enhance their molecular recognition ability which favours the development of high-performance separation technologies, advanced sensors, drug-delivery systems, and materials synthesis [13].

In this work, LLC in lamellar mesophases doped with dicationic ionic liquids (DIL) were investigated under Small Angle X-ray Scattering (SAXS) and Polarized Optical Microscopy (POM) techniques. The DILs used are geminal dicationic liquids formed of imidazolium, pyrrolidinium, and pyridinium-based cations containing Br\(^-\) as an anion (Figure 1). Two different linkage chains were studied (n = 6 and n = 8), and the effects of these structural variations on the mesophases were examined.

**Experimental section**

**Materials**

**Lyotropic liquid crystals**

Binary mixtures of a non-ionic surfactant and water were prepared with Triton X-100 from Sigma Aldrich and distilled water. The concentration of 70%wt %Triton X-100 was used for lamellar mesophase [14]. Samples were prepared by mixing all components in a vortex and using an ultrasound bath and centrifugation for homogenization. For doped LLC, solid DIL-1-5 were directly added to the lamellar matrix.

**Dicationic ionic liquids**

All geminal dibromide dicationic ionic liquids were prepared in high purity using standard methods described in the literature [15] - [22]. The DIL-1-5 compounds were obtained as pure amorphous white solids in 60–85% yield, and were fully characterized by \(^1\)H and \(^{13}\)C NMR.

1,6-Bis(1-methylimidazolium-3-yl)hexane dibromide \([\text{C}_6(\text{C}_1\text{Im})_2][\text{Br}_2]\) (DIL-1) [15], [16]. \(^1\)H NMR (300 MHz, D\(_2\)O) \(\delta\) 1.26-1.39 (m, 4H), 1.76–1.92 (m, 4H), 3.87 (s, 6H), 4.17 (t, \(J = 7.1\) Hz, 4H), 7.41 (s, 2H), 7.45 (s, 2H), 8.69 (s, 2H); \(^{13}\)C NMR (75 MHz, D\(_2\)O) \(\delta\) 24.8, 29.1, 35.7, 49.4, 122.2, 123.5, 135.8.

1,8-Bis(1-methylimidazolium-3-yl)octane dibromide \([\text{C}_8(\text{C}_1\text{Im})_2][\text{Br}_2]\) (DIL-2) [15], [17]. \(^1\)H NMR (300 MHz, D\(_2\)O) \(\delta\) 1.30 (br s, 8H), 1.77–1.89 (m, 4H), 3.87 (s, 6H), 4.17 (t, \(J = 7.1\) Hz, 4H), 7.41 (s, 2H), 7.46 (s, 2H), 8.70 (s, 2H); \(^{13}\)C NMR (100 MHz, D\(_2\)O) \(\delta\) 25.2, 27.8, 29.1, 35.7, 49.5, 122.2, 123.5, 135.8.

1,6-Bis(1-methylpyrrolidinium-3-yl)hexane dibromide \([\text{C}_6(\text{C}_1\text{Pyrr})_2][\text{Br}_2]\) (DIL-3) [18], [19]. \(^1\)H NMR (300 MHz, D\(_2\)O) \(\delta\) 1.38–1.49 (m, 4H), 1.74–1.89 (m, 4H), 2.11–2.26 (m, 8H),
3.03 (s, 6H), 3.30–3.36 (m, 4H), 3.42–3.57 (m, 8H); $^{13}$C NMR (75 MHz, D$_2$O) δ 21.3, 23.0, 25.3, 48.1, 64.0, 64.3.

1,8-Bis(1-methylpyrrolidium-3-yl)octane dibromide [C$_8$(C$_1$Pyrr)$_2$][Br$_2$] (DIL-4) [20], [21]. $^1$H NMR (300 MHz, D$_2$O) δ 1.3–1.42 (m, 8H), 1.71–1.83 (m, 4H), 2.12–2.25 (m, 8H), 3.02 (s, 6H), 3.28–3.33 (m, 4H), 3.42–3.52 (m, 8H); $^{13}$C NMR (75 MHz, D$_2$O) δ 21.3, 23.0, 25.2, 27.9, 48.0, 64.3.

1,6-Bis(pyridinium-1-yl)hexane dibromide [C$_6$(Py)$_2$][Br$_2$] (DIL-5) [22]. $^1$H NMR (300 MHz, D$_2$O) δ 1.35–1.45 (m, 4H), 1.96–2.09 (m, 4H), 4.61 (t, $J = 7.4$ Hz, 4H), 8.06 (t, $J = 7.1$ Hz, 4H), 8.50–8.57 (m, 2H), 8.84 (d, $J = 5.7$ Hz, 4H). $^{13}$C NMR (75 MHz, D$_2$O) δ 24.8, 30.3, 61.7, 128.3, 144.2, 145.6.

**Polarized optical microscopy**

The samples were encapsulated inside micro slides 0.2 mm thickness sealed with Parafilm®, placed in an INSTECH HS1-i hot stage system, and positioned in a Leitz orthoplan-pol microscope. Micrographics were taken with a digital camera coupled to the microscope and temperature was varied from 6°C to 40°C, to avoid sample evaporation.

**Small angle X-ray scattering**

SAXS experiments were performed in a Xenocs Xeuss SAXS/WAXS system. It has a GeniX beam delivery system with a Cu anode X-ray tube ($\lambda = 0.15411$ nm), two scatterless slits as a collimator, and a two-dimensional Dectris Pilatus 300 K detector which registers the patterns. The beam delivered to the samples has a square cross-section of 0.5 mm × 0.5 mm. The exposure time for SAXS measurements in each sample was 15 min. The circular averaging of the two-dimensional images were made using the SOLEIL Foxtrot software. The scattering vector modulus is defined as $q = (4\pi \sin \theta)/\lambda$, where $2\theta$ is the scattering angle. Samples were encapsulated in capillary glass tubes 1.5 mm diameter and measurements were performed at a controlled temperature of 6°C.

**Results and discussion**

Firstly, all prepared samples were observed in a polarised optical microscope positioned on a hot stage, as described before. The temperature was varied from about 6°C up to 40°C, and micrographics were taken with a digital camera coupled to the microscope; In Figure 2 showed some of them.

![Figure 2](image_url). Microscopic textures of the 70 wt% Triton-X100-water binary system. The samples were observed for temperatures from 6°C to 40°C, at a rate of about 0.5°C/min, encapsulated in micro slide de 0.2 mm thickness using with 10X magnification, at 45° with a polariser (P) and analyser (A). (a) Lamellar matrix doped with DIL-5, exhibiting lamellar texture at 9°C, (b) lamellar matrix doped with DIL-2 exhibiting lamellar texture at 5.3°C, (c) non-doped lamellar matrix, exhibiting Maltese crosses in the centre and colourful borders at 9°C.
POM enabled the construction of a phase diagram, Figure 3, with transitions temperatures for all investigated samples. Phase transitions temperatures slightly change: for DILs with $n = 8$; a small decreasing of transition temperature lamellar-isotropic phase was noticed; for DILs with $n = 6$ a small region (about 2°C) of coexistence phase appeared between lamellar and isotropic phase, reducing the lamellar phase in comparison to $n = 8$.

SAXS experiments were performed at 6°C of temperature, in lamellar mesophase, for all samples. Figure 4 shows SAXS results for the lamellar matrix (black line) and samples doped with three different DIL: DIL-1 (marine line), DIL-3 (olive line) and DIL-5. All curves presented the lamellar mesophase signature, a relation 1:2 of the Bragg peaks positions [23], [24]. The addition of the dicaticion ionic liquids increased the intensity of SAXS curves in 50% up to 100%, pointing to more ordered structures. In detail, it is also possible to see a peak position deviation for small values of scattering vector, $q$, for first and second order peaks, that means an enlargement of the lamellar structure for all DILs. The values for lamellar periodicity [23] (spacing), $d = 2\pi/q_1$, where $q_1$ refers to the first peak, and DILs concentrations for each sample can be found in Table 1.

A comparison of the influence of the number of carbons ($n = 6$ and $n = 8$) in the central chain of DIL was done (Figure 5) for $C_n(C_{1}\text{Im})_2Br_2$ and $C_n(C_{1}\text{Pyr})_2Br_2$. There is a small shift to the right of peak positions with increasing carbon number, but the relation 1:2 is preserved, as well the peak intensity, indicating that lamellar mesophase is preserved but with a small lamellar periodicity $d$.

Using the lamellar periodicity, $d$, which was found for the pure lamellar mesophase, we calculated membranes thickness, $d_m$, and water layer thickness, $d_w$, where $d = d_m+d_w$, and...
Table 1. Results of lamellar periodicity for lamellar phase obtained from SAXS experiments at 6°C.

| Abbreviation | Dication ionic liquid dopant | DIL concentration (mols%) | Bragg peak positions relationship | d (Å) |
|--------------|-----------------------------|---------------------------|----------------------------------|-------|
| L            | No doping                   | 0                         | 1:2                              | 46.61 |
| DIL-1        | C₆(C₇Im)₂(Br)₂               | 0.22                      | 1:2                              | 47.67 |
| DIL-2        | C₈(C₇Im)₂(Br)₂               | 0.28                      | 1:2                              | 47.38 |
| DIL-3        | C₆(C₇Pyrr)₂(Br)₂             | 0.40                      | 1:2                              | 48.00 |
| DIL-4        | C₆(C₇Pyrr)₂(Br)₂             | 0.22                      | 1:2                              | 47.42 |
| DIL-5        | C₈(Py)₂(Br)₂                 | 0.48                      | 1:2                              | 48.00 |

Figure 5. SAXS results for C₆(C₇Im)₂Br₂ (above) and C₆(C₇Pyrr)₂Br₂ (below) for n = 6 and n = 8. DIL-1 (olive line), DIL-2 (purple line), DIL-3 (marine line) and DIL-4 (orange line). The error bars are comparable to the line thickness and were omitted for clarity.

\[ d = \frac{d_m}{(1-vf_w)} \], where \( vf_w \) is the volumetric water fraction, getting \( d_m = 31.97 \) Å and \( d_w = 14.64 \) Å. The addition of the DILs studied in this paper in a lamellar meso-phase lead to a more ordered lamellar meso-phase, with a larger lamellar periodicity \( d \). The increasing in lamellar periodicity with DIL doping may be due to an increase of water layer thickness or membrane thickness.

DILs molecules are shorter than Triton-X molecules, and its interaction with the hydrophilic part of Triton-X promote an enlargement of the water layer, more significant for DIL-3 and DIL-5, in comparison with DIL-1 (Table 2).

Figure 6 shows the dependence of water layer thickness (\( d_w \)) with the proportion of the number of DIL molecules compared with Triton X (DIL/TRX). The increase of DIL/TRX causes an increase of \( d_w \). For DILs with \( n = 6 \), the values of DIL/TRX are 0.08, 0.07 and 0.06, for DIL-5, DIL-1 and DIL-3, respectively, while for DILs with \( n = 8 \) are 0.04 for DIL-2 and 0.03 for DIL-4. This result shows that the lamellar periodicity depends on mainly of the molar

Table 2. Water layer thickness, \( d_w \), for lamellar phase obtained from SAXS experiments at 6°C.

| Abbreviation | \( d_w \) (Å) |
|--------------|--------------|
| L            | 14.64        |
| DIL-1        | 16.04        |
| DIL-2        | 15.64        |
| DIL-3        | 16.09        |
| DIL-4        | 15.46        |
| DIL-5        | 16.22        |
ratio between DIL and Triton-X. Molecular interactions between Triton-X and DIL may be contributing to a tight molecular arrangement, leading to a more rigid structure.

When comparing changes as a function of alkyl chain length (n = 6 or 8) it is possible to verify that DILs with smaller chain (n = 6) promote an increasing in lamellar periodicity larger than that promoted with DILs with larger chain (n = 8).

As a conclusion, the doping LLC with DIL practically does not affect phase transition temperatures and promote a better organisation of the system. The periodicity of the lamellar phase can be tunable with DIL dopings, what can be very useful to applications for lamellar LLC.
