Space-Time Invariant Measures, Entropy, and Dimension for Stochastic Ginzburg–Landau Equations

Jacques Rougemont

Department of Mathematics, Heriot–Watt University, Edinburgh EH14 4AS, United Kingdom.

Abstract

We consider a randomly forced Ginzburg–Landau equation on an unbounded domain. The forcing is smooth and homogeneous in space and white noise in time. We prove existence and smoothness of solutions, existence of an invariant measure for the corresponding Markov process and we define the spatial densities of topological entropy, of measure-theoretic entropy, and of upper box-counting dimension. We prove inequalities relating these different quantities. The proof of existence of an invariant measure uses the compact embedding of some space of uniformly smooth functions into the space of locally square-integrable functions and a priori bounds on the semi-flow in these spaces. The bounds on the entropy follow from spatially localised estimates on the rate of divergence of nearby orbits and on the smoothing effect of the evolution.
1 Introduction

The use of dynamical system techniques and ideas in the study of extended partial differential equations has proved extremely fruitful in the past, see for example P. Collet’s talk at ICM’98, [C2] (where he also emphasises the limitations of such an approach). However, until now only results using topological or geometric properties of the dynamics have been used (like invariant manifolds, bifurcation theory, topological entropy, Hausdorff dimension). That is to say, extended dynamical systems are usually regarded as topological dynamical systems. In contrast, most of the very deep results in finite dimensional dynamical systems use measure-theoretic ideas, namely ergodic theory (as advocated for instance in the review by L.-S. Young at the ICMP in 1997, [Y2]).

One of the favourite models of infinite dimensional dynamical systems studied recently is the Ginzburg–Landau equation. It appears as a generic normal form describing the amplitude of periodic bifurcated solutions (see [C2]) and it is also believed to be a good example of spatio-temporally chaotic dynamics [LO]. It is known that its attractor is infinite-dimensional and has positive ε-entropy (see [CE1, CE2, CE3, Ro]).

Here we propose to use random perturbations to obtain, by probabilistic techniques, the existence of invariant measures for the corresponding random dynamical system. The existence result is based on the observation by J. Ginibre and G. Velo that the Ginzburg–Landau equation has global solutions both in uniformly local Sobolev spaces and in local $L^2$ space. Their proofs go through to the stochastic case without much effort, if we assume the noise to be smooth in space. Since uniformly local Sobolev spaces of sufficiently high order are compactly embedded into local $L^2$ space, we get the Feller property of the semi-group and the tightness of the Cesàro means therefore existence of an invariant measure (by standard arguments for stochastic differential equations, see [DZ1]). These measures are also translation invariant, because the noise, the deterministic part of the equation and the spaces used are all translation invariant. We refer to the property of being invariant under the time evolution as “stationarity” and the invariance under space translations as “homogeneity” of the measure, following Vishik and Fursikov [VF].

In a second part of the paper we define the topological entropy and the measure-theoretic entropy, or rather their spatial densities, since both quantities are extensive (this has been discovered in this context by Collet and Eckmann in [CE1], see e.g. [Ru] for earlier similar ideas). Usual inequalities from ergodic theory can be proved in this case and the Collet-Eckmann bound on the topological entropy is also valid (see [CE2]).

The paper is organised as follows: In Section 2, we set the model and the functional analysis background needed for the remainder of the paper. The main results of the paper are summarised in Section 3. In Section 4 we obtain uniform bounds on the solutions in Sobolev spaces, these bounds being then used in Section 5 to prove the existence of invariant measures. Section 6 is devoted to the results on existence and properties of the (measure-theoretic and topological) entropies. Various technical proofs have been relegated to Sections 7–12.

We finish this introduction by commenting on the fact that many new results on invariant measures for nonlinear PDEs have recently appeared. We mention for instance [BKL, FM, EH, KS, Ku, Ma, S]. To the best of our knowledge the present work is the first where the model considered enjoys: infinite volume (hence continuous spectrum without gap), genuinely nonlin-
ear interaction, homogeneous noise (hence infinite supply of energy at each time), non-trivial deterministic dynamics (e.g. the attractor of the deterministic Ginzburg–Landau is infinite dimensional). However, we are still unable to prove uniqueness of the invariant measure (i.e. an ergodicity result, as for example in [KS, F1, FM, M, BKL, DZ]).

2 Model and Definitions

We consider equations of the form

\[\begin{align*}
\frac{du}{dt} &= \left( (1 + i\alpha)\Delta u + u - (1 + i\beta)|u|^{2q}u \right) dt + \xi dw(t), \\
u(x,t) &\in C, \quad x \in \mathbb{R}^d, \quad t \geq 0, \quad \alpha, \beta \in \mathbb{R},
\end{align*}\]

(2.1)

where \(w(t)\) is a Wiener process and Eq.(2.1) is understood as an Itô stochastic differential in \(t\). For a while we simply assume \(\xi(\cdot, t) \in C^\infty_b(\mathbb{R}^d)\) uniformly in \(t\) and it is adapted to the Wiener process in \(t\). A specific example will be considered in Section 5. We also assume \(u(\cdot, 0) = u_0 \in C^\infty_b(\mathbb{R}^d)\). We make the following

Hypothesis 2.1. We assume \(d \leq 2, q > \frac{1}{2}\), and

\[-(1 + \alpha\beta) < |\alpha - \beta|\frac{\sqrt{2q + 1}}{q}, \quad |\beta| \leq \frac{\sqrt{2q + 1}}{q}. \]

(2.2)

Remark. The second inequality in (2.2) implies the first one. We wrote the first one because it appears in this form in the proof of Proposition 4.4, while the second condition appears in the proof of Lemma 10.3, see Ginibre and Velo [GV1, GV2] for the most general results available in this direction.

We next introduce the function spaces used in this paper. Let

\[\varphi_{\delta,y}(x) = \exp\left(-\sqrt{1 + \delta^2|x-y|^2}\right).\]

(2.3)

The main feature of this function is that it belongs to \(L^p\) for all \(p\) and

\[\|\nabla^n \varphi_{\delta,y}\|_{\infty} = A_n \delta^n < \infty\]

(2.4)

for all \(y \in \mathbb{R}^d\) and \(n \in \mathbb{N}\). This function is used as weight on Sobolev and Lebesgue spaces:

Definition 2.2. The local Lebesgue space \(L^2_{\delta,y}\) is defined as the completion of \(C^\infty_b\) (bounded smooth functions) in the norm induced by the scalar product

\[\langle f, g \rangle_{\delta,y} = \int \varphi_{\delta,y}(x) \overline{f(x)}g(x) \, dx.\]
The local Sobolev spaces $H^m_{\delta,y}$ are defined as

$$H^m_{\delta,y} = \{ f : \nabla^k f \in L^2_{\delta,y}, \ k = 0, \ldots, m \}.$$ 

The uniformly local Sobolev spaces $H^m_{ul}$ are defined as the completion of $C^\infty_b$ in the norm

$$\| f \|_{H^m_{ul}}^2 = \sum_{k=0}^{m} \sup_{y \in \mathbb{R}^d} (\nabla^k f, \nabla^k f)_{\delta,y}.$$ 

Remark that $H^m_{ul}$ is actually independent of $\delta > 0$, since the following inclusion holds:

$$H^m_{ul} = \bigcap_{y \in \mathbb{R}^d} H^m_{\delta,y} \subset \bigcap_{\delta > 0} H^m_{\delta,y}.$$  \(2.5\)

Usual Sobolev embeddings hold \cite{Ad}, for example if $m > d/2$, the inequality

$$\| f \|_{H^m_{ul}} \leq C \delta \| f \|_{H^m_{ul}}$$  \(2.6\)

implies the continuous embedding $H^m_{ul} \hookrightarrow L^\infty$. Moreover, by the Rellich–Kondrachov Theorem \cite{Ad},

$$H^{m+k}_{\delta,y} \hookrightarrow H^m_{\delta',y}$$  \(2.7\)

is compact if $k > d/2$ and $0 < \delta < \delta'$ (see Section \(\square\)).

Notations. Throughout the paper, $\overline{z}$ denotes the complex conjugate of $z$, $f_t(x) \equiv f(x, t)$ hence $\| f_t \|_X$ is the norm of $f(x, t)$ in the space $\mathcal{X}(dx)$ (e.g. $\mathcal{X} = L^2$). Norms in Lebesgue spaces $L^p$ are denoted $\| \cdot \|_p$ ($\| \cdot \|$ is usually the norm on $L^2_{\delta,y}$ for the current choice of $\delta$ and $y$). Expectations and probabilities with respect to the Wiener measure are denoted $E$ and $P$. We denote the integer part of the positive real $x$ by $[x] \equiv \max\{n \in \mathbb{N} : n \leq x\}$. Symbols $C, C_1, C_2, \ldots, c, c_1, c_2, \ldots$ usually denote generic numerical constant. The product $f \ast g$ means the convolution of the functions $f$ and $g$. The cube of side $L$ and centre $0$ in $\mathbb{R}^d$ is $Q_L = [-\frac{1}{2} L, \frac{1}{2} L]^d$.

### 3 Summary of Results

In this section, we describe in a rather informal way the main results of this paper. The first result (Section \[3\]) is the following theorem of existence of smooth bounded solutions to Eq.\(2.1\):

**Theorem A.** If Hypothesis \ref{2.7} holds, then Eq.\(2.7\) with initial data $u_0 \in C^\infty_b$ has a unique solution $u(x, t) = u_t(x)$. For all real $p \geq 1$ and integer $m$, there is a $B_{p,m} < \infty$ such that for all $t > 0$:

$$E \| u_t \|_{H^m_{ul}}^p \leq B_{p,m}.$$ 

The proof relies on well-known estimates \cite{GV1, Mi, C1} using the dissipative nature of the nonlinear term in Eq.\(2.1\) for the deterministic part and on Itô’s Lemma to treat the stochastic
term. Actually, in the evolution equation for $E\|u_t\|_{H_{ul}^m}^p$, Itô’s Lemma only generates terms which are dominated by the nonlinear dissipative term and this implies that the techniques which were developed for the deterministic equation are applicable.

By Lemma 10.3 we can extend the existence result to the space $L^2_{\delta,y}$, hence we can define the Markovian Feller semi-group $P_t$ acting on $C_b(L^2_{\delta,y}, C)$ for any specific choice of $y$, for example $y = 0$:

$$ (P_t f)(u) = \int_{t^2_{\delta,0}} f(\eta) P(u_t \in d\eta). $$

An invariant measure for Eq.(2.1) is a fixed point of the dual semi-group $P_t^*$. We next assume that $\xi$ is an homogeneous process adapted to the Brownian motion. Since $H_{ul}^m$ is compactly embedded into $L^2_{\delta,y}$ for $m > d/2$ (see (2.7)) the following theorem (see Section 5) is an immediate consequence of Theorem A by the Prokhorov and Krylov–Bogolyubov Theorems (see [Ar, VF, DZ2]):

**Theorem B.** There exists at least one invariant measure $\mu$ for Eq.(2.1). This measure is homogeneous in $x$ and its support is contained in $\bigcap_{m \geq 0} H_{ul}^m$.

Finally, in Section 6 we define the random attractor (see [CDF])

$$ A_\omega = \bigcup_{R > 0} A(\omega, R), $$

$$ A(\omega, R) = \bigcap_{T > 0} \bigcup_{t > T} \Phi^t_{\theta - t \omega}(B_R). $$

Here and below $\Phi^t_{\omega}$ is the semi-group generated by Eq.(2.1), $\theta^t$ is the time-shift of the noise, and $T_x$ the group of spatial translations. Moreover $B_R \subset H_{ul}^m$ is the ball of radius $R$ and centre 0. We introduce the following dynamical observables (see [KH, LQ]):

$$ h_{top} = \lim_{\varepsilon \to 0} \lim_{L \to \infty} \frac{1}{L^d} \lim_{n \to \infty} \frac{1}{n_T} \int \log N_{\omega,n,T,Q_L,\varepsilon} P(d\omega), $$

$$ h_{\mu} = \lim_{\varepsilon \to 0} \lim_{L \to \infty} \frac{1}{L^d} \lim_{n \to \infty} \frac{1}{n_T} \int H_{\mu} \left( \bigvee_{x \in \mathbb{Z}^d \cap Q_L} \bigvee_{k=0}^{n-1} \Phi^{-k\tau}_{\omega} T_{-x}(\Sigma_{\theta^k T_x \omega, \varepsilon}) \right) P(d\omega), $$

$$ H_{\varepsilon} = \lim_{L \to \infty} \int \frac{\log M_{\varepsilon,Q_L,\omega}}{L^d} P(d\omega), $$

$$ d_{up} = \lim_{\varepsilon \to 0} \sup \frac{H_{\varepsilon}}{\log \varepsilon^{-1}}, $$

where $N_{\omega,n,T,Q_L,\varepsilon}$ is the cardinality of a minimal $(n, \varepsilon)$–cover of $A_\omega|_{Q_L}$, $\Sigma_{\omega,\varepsilon}$ is a sequence of partitions of $A_\omega$ in sets of diameter at most $\varepsilon$ in the metric of $L^\infty(Q_L)$, $M_{\varepsilon,Q_L,\omega}$ is the least cardinality of an $\varepsilon$–cover of $A_\omega|_{Q_L}$ and $Q_L = [-\frac{1}{2}L, \frac{1}{2}L]^d$ (see Section 7 for detailed definitions).

The quantities in Eq.(3.1) are called respectively the topological entropy, the metric or measure-theoretic entropy [KH], the Kolmogorov–Tikhomirov $\varepsilon$–entropy [KT] and the upper (box-counting) dimension. It is important to note that the above numbers are all spatial densities (limit
as $L \to \infty$ of quantities divided by $L^d$) although the limits are not taken in the most natural order. They are thus spatially localised versions of the usual entropies and dimensions.

We then prove the following estimates:

**Theorem C.** There is a $\gamma < \infty$ such that $h_\mu \leq h_{\text{top}} \leq \gamma d_{\text{up}} < \infty$.

The proof that all the various limits in Eq. (3.1) exist relies on standard subadditive bounds \[KH\]. The upper bound on $d_{\text{up}}$ follows from spatially localised estimates of the rate of divergence of nearby orbits (Lemma 6.7) as well as the smoothing action of the evolution (see Section 7, in particular Lemma 7.1). It is similar to the proof of the deterministic case \[CE2\].

## 4 Bounded Smooth Solutions

Our first result in this paper is the existence (and uniqueness by Lemma 10.1) of smooth bounded solutions to Eq. (2.1).

**Theorem 4.1.** If Hypothesis 2.1 holds, then Eq. (2.1) with initial data $u_0 \in C_0^\infty$ has a unique solution $u(x, t) = u_t(x)$. For all real $p \geq 1$ and integer $m$, there is a $B_{p, m} < \infty$ such that for all $t > 0$:

$$E\|u_t\|_{H^m_{\text{ul}}}^p \leq B_{p, m}.$$

**Remark.** This proof is amply simplified by our assumptions on the regularity of $\xi_t$ in Eq. (2.1). A much more general theory of stochastic PDEs on $\mathbb{R}^d$ can be found, for example, in Krylov [Kr]. Funaki [F1, F2] has studied a similar equations with stronger assumptions on the nonlinearity and Eckmann–Hairer [EH] have recently proved a similar result for stochastic forcings with finite energy.

**Proof.** In the first part of the proof, we fix $y \in \mathbb{R}^d$ and $\delta > 0$ such that $A_1 \delta + A_2 \delta^2 < 1$ (see Eq. (2.4)). We write $\| \cdot \|$ and $(\cdot, \cdot)$ for the norm and scalar product in the corresponding space $L^2_{\delta, y}$.

All bounds will actually turn out to be uniform in $y$. We stress that scalar products denoted $(\cdot, \cdot)$ contain the weight $\varphi_{\delta, y}$ (see Definition 2.2) hence integration by parts produces commutators of the form $\nabla \varphi_{\delta, y}/\varphi_{\delta, y}$. From now on, we also write $\varphi$ for $\varphi_{\delta, y}$.

Let $\mathcal{L} = (1 + i \alpha) \Delta + 1$. For $f \in D_m(\Delta) \subset H^m_{\delta, y}$ (the domain of the closure in $H^m_{\delta, y}$ of $\Delta$ with core $C_0^\infty$), the following holds by Eq. (2.4):

$$\text{Re} \left(\nabla^m f, \nabla^m \mathcal{L} f \right) = \left(\nabla^{m+1} f, \nabla^{m+1} f \right) + \left(\nabla^m f, \nabla^m f \right) + \text{Re} \left(\nabla \varphi^{-1} \nabla^m f, (1 + i \alpha) \nabla^{m+1} f \right)$$

$$\leq -\frac{1}{2} \left(\nabla^{m+1} f, \nabla^{m+1} f \right) + \left(1 + \frac{1}{2}(1 + \alpha^2) \right) \left(\nabla^m f, \nabla^m f \right).$$

Namely $\mathcal{L} = (1 + (1 + \alpha^2)/2)$ is a dissipative operator hence by the Lumer–Phillips Theorem \[Y1\], $\hat{\mathcal{L}}$ generates a strongly continuous quasi-bounded semi-group $\exp(t \mathcal{L})$ on $H^m_{\delta, y}$, with

$$\|\exp(t \mathcal{L})\|_{H^m_{\delta, y} \to H^m_{\delta, y}} \leq e^{ct} \quad (4.1)$$
for some \( c < \infty \). Remark that we may have chosen \( \delta \) such that \( c = 1 + \varepsilon \) for arbitrarily small \( \varepsilon > 0 \).

We define mild solutions to Eq. (2.1) in \( \mathbb{H}_{\delta,y}^{m} \) by the Duhamel formula (and the Itô integral):

\[
z_t = e^{t\mathcal{L}}z_0 - (1 + i\beta) \int_0^t e^{(t-s)\mathcal{L}}|z_s|^{2q} z_s \, ds + \int_0^t e^{(t-s)\mathcal{L}}\zeta_s \, dw_s. \tag{4.2}
\]

We let \( P_M : \mathbb{R}^+ \rightarrow \mathbb{R}^+ \) be a smooth cutoff function satisfying \( P_M(x) = 1 \) if \( x < M \) and \( P_M(x) = 0 \) if \( x > M + 1 \). We introduce this cutoff into the nonlinear term above, effectively rendering the nonlinearity uniformly Lipschitz:

\[
\tilde{z}_t = e^{t\mathcal{L}}z_0 - (1 + i\beta) \int_0^t e^{(t-s)\mathcal{L}} P_M(|z_s|)|z_s|^{2q} z_s \, ds + \int_0^t e^{(t-s)\mathcal{L}}\xi_s \, dw_s. \tag{4.3}
\]

We next define the random stopping time \( \tau(R) \) by

\[
\tau(R) = \min\{ t > 0 : \|\tilde{z}_t\|_{\infty} \geq R \}. \tag{4.4}
\]

We fix arbitrarily a positive number \( R < M \), and if \( \chi_I \) denotes the characteristic function of the set \( I \), we consider the following integral equation for \( t < \tau(R) \):

\[
u_t = e^{t\mathcal{L}}u_0 - (1 + i\beta) \int_0^t e^{(t-s)\mathcal{L}} P_M(|u_s|)|u_s|^{2q} u_s \chi_{\{ s \leq \tau(R) \}} \, ds + \int_0^t e^{(t-s)\mathcal{L}}\xi_s \chi_{\{ s \leq \tau(R) \}} \, dw_s. \tag{4.5}
\]

The following is a simple consequence of our construction:

**Lemma 4.2.** There is almost surely a unique function \( u_t \) satisfying Eq. (4.5), this function is independent of \( M > R \) and it also satisfies Eq. (4.2) for \( t < \tau(R) \).

**Proof.** See [1, 2] for the properties of the stochastic convolution and Section 3 for the contraction argument needed to prove uniqueness. \( \square \)

The remaining part of the proof of Theorem 4.1 follows very closely the paper by Mielke [3], which is based on [4, 5, 6]. We first establish uniform bounds in \( \mathbb{L}^{2}_{\delta,y} \).

**Lemma 4.3.** For all \( \delta > 0 \) and \( p \geq 1 \), there are \( C_{0,p}(\delta) \) such that the following bound holds for all \( t > 0 \) and all \( y \in \mathbb{R}^d \):

\[
E\|u_t\|_{\mathbb{L}^{2}_{\delta,y}}^p \leq C_{0,p}(\delta). \tag{4.6}
\]

**Proof.** We first estimate the square of the norm in \( \mathbb{L}^{2}_{\delta,y} = \mathbb{L}^{2} \). By Itô’s formula, we have

\[
\text{d}\|u_t\|^2 = -2\|\nabla u_t\|^2 \, dt - 2\text{Re} (\nabla \varphi \varphi^{-1} u_t, (1 + i\alpha) \nabla u_t) \, dt + 2\|u_t\|^2 \, dt
\]

\[
- 2\text{Re} (u_t, (1 + i\beta)|u_t|^{2q} u_t) \, dt + \|\xi_t\|^2 \, dt + 2\text{Re} (u_t, \xi_t) \, dw_t,
\]

\[
\leq -\|\nabla u_t\|^2 \, dt + (2 + (1 + \alpha^2))\|u_t\|^2 \, dt - 2(u_t, |u_t|^{2q} u_t) \, dt
\]

\[
+ \|\xi_t\|^2 \, dt + 2\text{Re} (u_t, \xi_t) \, dw_t,
\]

\[
\leq -\|\nabla u_t\|^2 \, dt + C(\alpha, \|\xi_t\|, q) \, dt - \|u_t\|^2 \, dt + 2\text{Re} (u_t, \xi_t) \, dw_t. \tag{4.7}
\]
Proof. By Gronwall’s inequality, this is and we obtain
\[ E\|u_T\|^2 \leq E\|u_0\|^2 - E \int_0^T \|\nabla u_t\|^2 \, dt - E \int_0^T \left(\|u_t\|^2 - C\right) \, dt. \]

By Gronwall’s inequality, this is
\[ E\|u_T\|^2 \leq \max \left\{ C_{0,2}, \left( E\|u_0\|^2 - C_{0,2} \right) e^{-T} + C_{0,2} \right\}. \]

For higher powers of the \(L^2\) norm, we use Itô’s formula again:
\[ \frac{1}{p} \frac{d}{dt}\|u_t\|_{L^2}^{2p} = \|u_t\|^{2p-2}\|u_t\|^2 \, dt + 2(p-1)\|u_t\|^{2p-4} \left( \text{Re} \left( u_t, \xi_t \right) \right)^2 \, dt, \]

hence (after substituting the estimate (4.7))
\[ E\|u_T\|_{L^2}^{2p} \leq E\|u_0\|_{L^2}^{2p} - E \int_0^T \left(\|u_t\|^{2p} - C_{0,2p}\right) \, dt, \]

which by Gronwall’s inequality gives a uniform bound on \(\|u_t\|^p\) for \(p > 2\). For \(p \in [1, 2]\), we use Jensen’s inequality:
\[ E\|u_t\|^p \leq \left( E\|u_t\|^2 \right)^{p/2} \leq C_{0,2}^{p/2} = C_{0,p}. \]

If \(u_0\) is uniformly bounded and because \(\|\xi_t\|_{L^2_{y,u}}^p\) is bounded uniformly in \(y\) and \(t\), we obtain the uniform bound in the spaces \(L^2_{\delta,y}\) for all \(y\)
\[ \sup_{t>0} \sup_{y \in \mathbb{R}^d} E\|u_t\|_{L^2_{y,u}}^p \leq C_{0,p}(\delta), \quad (4.8) \]
which proves Lemma 4.3.

**Proposition 4.4.** For all \(\delta > 0\) and \(p \geq 1\), there are \(C_{1,p}(\delta)\) such that the following bound holds for all \(t > 0\) and \(y \in \mathbb{R}^d\):
\[ E\|u_t\|_{H^{1/2}_{y,u}}^p \leq C_{1,p}(\delta). \]

**Proof.** We first consider the differential
\[ d\|\nabla u_t\|^2 = -2\|\Delta u_t\|^2 \, dt + 2\text{Re} \left( \nabla \varphi^{-1} \nabla u_t, (1 + i\alpha) \Delta u_t \right) \, dt + 2\|\nabla u_t\|^2 \, dt \]
\[ + 2\text{Re} \left( \Delta u_t, (1 + i\beta)|u_t|^{2q} u_t \right) \, dt + 2\text{Re} \left( \nabla \varphi^{-1} \nabla u_t, (1 + i\beta)|u_t|^{2q} u_t \right) \, dt \]
\[ + \|\nabla u_t\|^2 \, dt + 2\text{Re} \left( \nabla u_t, \nabla u_t \right) \, dw_t \]
\[ \leq -2\|\Delta u_t\|^2 \, dt + 2\|\nabla u_t\|^2 \, dt + 2\text{Re} \left( \Delta u_t, (1 + i\beta)|u_t|^{2q} u_t \right) \, dt \]
\[ + 2\sqrt{1 + \alpha^2}\|\Delta u_t\| + \sqrt{1 + \beta^2}\|\xi_t\|^{2q+1}\|\nabla u_t\| \, dt \]
\[ + \|\nabla u_t\|^2 \, dt - 2\text{Re} \left( u_t, \varphi^{-1} \nabla (\varphi \nabla u_t) \right) \, dw_t, \quad (4.9) \]
The proof goes as follows: we first remark that integration by parts leads to

\[
\frac{1}{q+1} d||u_t||^2 dt = 2 \text{Re} \left( |u_t|^{2q} u_t (1 + i \alpha) \Delta u_t \right) dt + 2 ||u_t||^2 dt
\]

\[
- 2 ||u_t|^{2q} u_t||^2 dt + 2 q \left( \text{Re} \left( |u_t|^{q-1} u_t, \xi_t \right) \right)^2 dt + 2 \text{Re} \left( |u_t|^{2q} u_t, \xi_t \right) d\nu_t
\]

\[
\leq 2 \text{Re} \left( |u_t|^{2q} u_t (1 + i \alpha) \Delta u_t \right) dt + 2 ||u_t||^2 dt + 2 ||u_t||^2 ||u_t||^2 dt
\]

\[
- 2 ||u_t|^{2q} u_t||^2 dt + 2 \text{Re} \left( |u_t|^{2q} u_t, \xi_t \right) d\nu_t.
\]

(4.10)

We take a convex combination of Inequalities (4.10) and (4.9) (here \( \lambda \in [0, 1] \)):

\[
\frac{1}{2} \left( \lambda \nabla |u_t|^2 + \frac{(1 - \lambda)}{q+1} d||u_t||^2 \right)
\]

\[
\leq \left( \lambda \nabla |u_t|^2 + (1 - \lambda)||u_t||^2 \right) dt + \left( (1 - \lambda)q ||\xi_t||^2 ||u_t||^2 + \frac{\lambda}{2} \nabla |\xi_t|^2 \right) dt
\]

\[
+ \lambda \left( \sqrt{1 + \alpha^2} \nabla u_t + \sqrt{1 + \beta^2} \nabla |u_t|^{2q+1} \right) dt + \mathcal{M} dt + \text{Re} \left( -\lambda u_t, \varphi^{-1} \nabla (\varphi \nabla \xi_t) \right) + (1 - \lambda) b \left( |u_t|^{2q} u_t, \xi_t \right) d\nu_t.
\]

The term denoted by \( \mathcal{M} \) is treated separately:

\[
\mathcal{M} = - \left( \lambda \nabla |u_t|^2 + (1 - \lambda)||u_t||^2 \right) + \text{Re} \left( 1 - i(\lambda \beta - (1 - \lambda)\alpha) \right) \left( |u_t|^{2q} u_t, \Delta u_t \right)
\]

\[
\leq - \varepsilon \left( \lambda \nabla |u_t|^2 + \frac{(1 - \lambda)}{q+1} ||u_t||^2 \right) - \frac{2(1 - \varepsilon)}{\sqrt{\lambda(1 - \lambda)}} \left( |u_t|^{2q} u_t, \Delta u_t \right)
\]

\[
+ \text{Re} \left( 1 - i(\lambda \beta - (1 - \lambda)\alpha) \right) \left( |u_t|^{2q} u_t, \Delta u_t \right)
\]

\[
\equiv - \varepsilon \left( \lambda \nabla |u_t|^2 + \frac{(1 - \lambda)}{q+1} ||u_t||^2 \right) + \tilde{\mathcal{M}}(\varepsilon).
\]

Under Hypothesis 2.1, there is an \( \varepsilon > 0 \) such that \( \tilde{\mathcal{M}}(\varepsilon) \) is negative (see e.g. [GV1, Mi, BGO]). The proof goes as follows: we first remark that integration by parts leads to

\[
\left( |u_t|^{2q} u_t, \Delta u_t \right) = - \left( \nabla \varphi |u_t|^{2q} u_t, \nabla u_t \right) - (q + 1) \int \varphi |u_t|^{2q} \nabla u_t^2 \left( 1 + \frac{q}{1 + q} \right) \frac{\nabla u_t^2}{|u_t|^2}.
\]

The last bracket above is of the form \( 1 + z \). Its argument can be estimated as follows: \( |\arg(1 + z)| \leq \arcsin |z| = \arcsin \frac{q}{1 + q} \equiv \theta \). We plug this into \( \tilde{\mathcal{M}} \):

\[
\tilde{\mathcal{M}}(\varepsilon) \leq - (q + 1) \left( |u_t|^{2q}, |\nabla u_t|^2 \right) \left( 2(1 - \varepsilon) \sqrt{\frac{\lambda(1 - \lambda)}{1 + \cos \theta}} - |\lambda \beta - (1 - \lambda)\alpha| \sin \theta \right)
\]

\[
+ C(\alpha, \beta, \lambda, \varepsilon) ||u_t|^{2q+1}|| \nabla u_t||
\]
The curly bracket above can be made positive by suitably choosing $\lambda$ and $\varepsilon$, namely we take $\lambda = \cos^2 \eta$, we optimise for $\eta$ and we obtain the following condition, which is obviously fulfilled for small $\varepsilon > 0$ under Hypothesis 2.1 (remark that $1/\tan \theta = \sqrt{2q + 1/q}$):

$$-(1 + \alpha \beta) - |\beta - \alpha|/\tan \theta + \varepsilon(2 - \varepsilon)/\sin^2 \theta \leq 0,$$

(see Ginibre and Velo [GV1] for this argument, Mielke [Mi] has a slightly different formulation). We thus obtain

$$\frac{1}{2}(\lambda d ||\nabla u_t||^2 + \frac{(1 - \lambda)}{q + 1} ||u_t||^q + 1)^2 dt$$

$$+ (C_1 ||\nabla u_t||^2 + C_2 ||u_t||^q + 1) dt + (C_5 ||\xi_t||^2 ||u_t||^q + 2 + C_4 ||\nabla \xi_t||^2) dt$$

$$+ \text{Re} \left(-\lambda(u_t, \varphi^{-1} \nabla (\varphi \nabla \xi_t)) + (1 - \lambda) (||u_t||^2 u_t, \xi_t)\right) d\omega_t$$

$$\leq C dt - \frac{\varepsilon}{2} \left(\lambda ||\nabla u_t||^2 + \frac{(1 - \lambda)}{q + 1} ||u_t||^q + 1^2\right) dt$$

$$+ \text{Re} \left(-\lambda(u_t, \varphi^{-1} \nabla (\varphi \nabla \xi_t)) + (1 - \lambda) (||u_t||^2 u_t, \xi_t)\right) d\omega_t,$$

thanks to the following obvious inequality:

$$-||\Delta u_t||^2 \leq -\rho ||\nabla u_t||^2 + C\rho^2 ||u_t||^2$$

(4.11)

which holds for all $\rho > 0$ and for some $C > 0$. As before, we take expectations, integrate over $t$ and we use Gronwall’s inequality to find out the following bound:

$$\max \left\{E||\nabla u_T||^2, E||u_T||^{q+1}||^2\right\}$$

$$\leq \max \left\{C_{1,2}, (E||\nabla u_0||^2 + E||u_0||^{q+1}||^2 - C_{1,2})e^{-\varepsilon T} + C_{1,2}\right\}. \hspace{1cm} (4.12)$$

This and Lemma 4.3 prove Proposition 4.4.

We next consider solutions $z(x, t)$ to Eq. (4.2) with bounded initial condition. Proposition 4.4 on $u(x, t)$ implies the following:

**Proposition 4.5.** For all $p \geq 1$, there is a $C_{\infty, p}$ such that for all $t > 0$, the following holds

$$E||z_t||^p_{\infty} \leq C_{\infty, p}. \hspace{1cm} (4.13)$$

**Proof.** By the bound (2.6), if $d = 1$ then Proposition 4.4 implies the bound (4.13) for stopped solutions. If $d = 2$ we need a bound in $H_{d, p}^2$. This is easily achieved with the help of a Gagliardo–Nirenberg inequality which we prove in Section 12:
Lemma 4.6. Let \( f \in H^3_u(R^2) \). For all \( K > 0 \) there are \( C(K) \), \( \eta \) such that

\[
\int \varphi_{\delta,y}(x) \left| \Delta (|f(x)|^{2q} f(x)) \Delta f(x) \right| \, dx \\
\leq \frac{1}{K} \int \varphi_{\delta,y}(x)|\nabla^3 f(x)|^2 \, dx + C(K) \left( \sup_y \int \varphi_{\delta,y}(x)|f(x)|^{2(q+1)} \, dx \right)^\eta.
\]

We use Inequality (4.11) (with \( u_t \) replaced by \( \nabla u_t \), Lemma 4.6, and the estimate (4.12) to bound the time derivative of \( \| \Delta u_t \|_{L^2_{\delta,x}}^2 \):

\[
\frac{1}{2} \frac{d}{dt} \| \Delta u_t \|_{L^2_{\delta,x}}^2 \\
\leq -\frac{1}{2} \| \nabla^3 u_t \|_{L^2_{\delta,x}}^2 \, dt + (1 + (1 + \alpha^2)) \| \Delta u_t \|_{L^2_{\delta,x}}^2 \, dt \\
+ C(1 + \beta^2) \sup_y \| |u_t|^{q+1} \|_{L^2_{\delta,y}}^{2\eta} \, dt + \frac{1}{2} \| \Delta \xi_t \|_{L^2_{\delta,x}}^2 \, dt + \langle \Delta u_t, \Delta \xi_t \rangle_{\delta,x} \, dt \\
\leq \left( -\frac{1}{2} \frac{d}{dt} \| \Delta u_t \|_{L^2_{\delta,x}}^2 + C \right) \, dt + \langle u_t, \varphi^{-1} \Delta (\varphi \Delta \xi_t) \rangle_{\delta,x} \, dt,
\]

where \( C \) depends on the parameters in Eq.(2.1) (including \( \xi_t \)) and on \( \| u_t \|_{L^2_{\delta,x}}, \| u_t \|_{L^2_{\delta,x}}^{q+1} \), and \( \| \nabla u_t \|_{L^2_{\delta,x}}^2 \) which satisfy Bounds (4.6) and (4.12) (or rather some extension of it to deal with the power \( \eta \)). By the usual Gronwall inequality, this proves (4.13) for stopped solutions (Eq.(4.5)).

We now choose a very large \( n_0 \gg C_{0,2} + C_{1,2} + C_{2,2} \) and we let

\[
\mathcal{E}_n = \{ u : \exists t < \tau(2n) \text{ s.t. } \| u_t \|_{\infty} > n_0 + n \}
\]

where \( \tau \) is the stopping time from Eq.(4.4). By Tchebychev’s inequality, by Proposition 4.4 and (2.6) we have

\[
\sum_{n=1}^{\infty} P(\mathcal{E}_n) \leq \sum_{n=1}^{\infty} n^{-2} \sup_{t \leq \tau(2n)} E(\| u_t \|_{\infty}^2) < \infty.
\]

By the Borel–Cantelli Lemma, it means that almost surely only finitely many of the events \( \mathcal{E}_n \) happen, and hence \( \| u_t \|_{\infty} \) remains bounded as the cutoffs \( R \) and \( M \) in Eq.(4.5) are sent to infinity. Since \( \tau(R) > 0 \) a.s. for all \( R > 1 \) (by the a priori bound of Lemma 10.2) a uniform bound holds in a small interval of time and this can be iterated indefinitely. This implies uniform boundedness of \( z_t \) and a similar argument holds for \( \| z_t \|_{\infty}^p, p > 1. \)
Proof of Theorem 4.1. By Proposition 4.4, it only remains to show that $\|\nabla^m u_t\|^p$ is bounded for $m > 1$. Let $p = 2$. We assume that it is true for $m - 1$ and we consider

$$
\frac{1}{2} \frac{d}{dt} \|\nabla^m u_t\|^2
\leq -\frac{1}{2} \|\nabla^{m+1} u_t\|^2 dt + \left(1 + \frac{1}{2}(1 + \alpha^2)\right) \|\nabla^m u_t\|^2 dt
- \text{Re} (1 + i\beta) (\nabla^m u_t, \nabla^m (|u_t|^{2\alpha} u_t)) dt + \frac{1}{2} \|\nabla^m \xi_t\|^2 dt + \text{Re} (\nabla^m u_t, \nabla^m \xi_t) dw_t
\leq -\frac{1}{2} \|\nabla^{m+1} u_t\|^2 dt + \left(C_1 \|\nabla^m u_t\|^2 dt + C_2 \|u_t\|_{H_{m-1}^1}^2 + C_3\right) dt
+ (-1)^m \text{Re} (u_t, \varphi^{-1} \nabla^m (\varphi \nabla^m \xi_t)) dw_t .
$$

Using (4.11) (with $u_t$ replaced by $\nabla^{m-1} u_t$), Proposition 4.5, and the recursion assumption, this can be bounded by:

$$
\frac{1}{2} \frac{d}{dt} \|\nabla^m u_t\|^2 \leq \frac{1}{2} (-\|\nabla^m u_t\|^2 + C) dt + (-1)^m \text{Re} (u_t, \varphi^{-1} \nabla^m (\varphi \nabla^m \xi_t)) dw_t .
$$

We then take expectations and integrate:

$$
\mathbb{E} \|\nabla^m u_t\|^2 \leq \mathbb{E} \|\nabla^m u_0\|^2 - \mathbb{E} \int_0^t (\|\nabla^m u_s\|^2 - C) \, ds .
$$

The case $p \neq 2$ is similar. 

\[\square\]

5 Invariant Measures

We now turn to the problem of the existence of an invariant measure for the process defined by Eq. (2.1). We construct here an explicit example of a smooth homogeneous random forcing which admits evident generalisations. Let $\xi(x)$ be a $C^\infty$ almost periodic function on $\mathbb{R}^d$. Denoting $T_y \xi(x) = \xi(x + y)$, the set

$$
G = \{T_y \xi : y \in \mathbb{R}^d\}^{L^\infty}
$$

is a compact group which can be endowed with the normalised Haar measure $h$. We denote by $(G, \mathcal{F}_1, h)$ the corresponding probability space ($\mathcal{F}_1$ is the sigma-algebra of Borel sets) and by $\xi_y$ the corresponding random variable. Let next $w_\alpha(t)$ be a standard Brownian motion (vanishing at 0) on the probability space $(C_0(\mathbb{R}, \mathbb{R}), \mathcal{F}_2, \mathbb{W})$ ($\mathcal{F}_2$ is the sigma-algebra generated by the topology of uniform convergence on compact sets and $\mathbb{W}$ is the Wiener measure). Let $z_\alpha(t) = y(t) - y(0)$ be a continuous process on $(G, \mathcal{F}_1, h)$ adapted to the filtration generated by the Brownian motion. We define the stochastic differential $\xi_{y(0)+z_\alpha(t)}(x) \, dw_\alpha(t)$ on the probability space $(\Omega, \mathcal{F}, \mathbb{P}) = (C_0(\mathbb{R}, \mathbb{R}) \times G, \mathcal{F}_2 \times \mathcal{F}_1, \mathbb{W} \times h)$. Let $\Xi_\omega(x, t)$ denote $\xi_{y(0)+z_\alpha(t)}(x) \, dw_\alpha(t)$ where $\Omega \ni \omega = (\alpha, y(0)) \in C_0(\mathbb{R}, \mathbb{R}) \times G$. By the nature of Haar measures, $\mathbb{P}$ is homogeneous in $x$, i.e. $T_y^* \mathbb{P} = \mathbb{P}$ for all $y \in \mathbb{R}^d$ (see Vishik and Fursikov [VF] for a discussion of homogeneous measures).
Let $\Phi^t_\omega$ be the semi-flow generated by Eq. (2.1) with noise $\Xi_\omega(x, t)$. Using Lemma [10, 3], we can define a Markov semi-group $P_t$ acting on $C_b(L^2_{\delta,0}; C)$ by

$$ (P_t f)(u) = \int_{L^2_{\delta,0}} f(\eta) P\left(\Phi^t_\omega(u) \in d\eta\right). $$

Theorem 5.1. There exists at least one invariant measure $\mu$ for Eq. (2.1). This measure is homogeneous in $x$ and its support is contained in $\bigcap_{m=0} H^m_{ul}$.  

Proof. We consider the family of measures $\{\bar{\mu}_t\}_{t>0}$, where

$$ \bar{\mu}_t = \frac{1}{t} \int_0^t P_s^* \delta_0 \, ds, $$

$\delta_0$ being the unit mass at $0 \in L^2_{\delta,0}$. By Theorem [4.1], this family is tight in $L^2_{\delta,0}$ for all $\delta > 0$. Namely for any $\varepsilon > 0$ there is a compact $K_\varepsilon \subset L^2_{\delta,0}$ such that $\bar{\mu}_t(K_\varepsilon) > 1 - \varepsilon$. For the set $K_\varepsilon$, we choose the ball of radius $R(\varepsilon)$ in $H^m_{ul}$ $(m > d/2)$ for sufficiently large $R(\varepsilon)$ and the compactness follows from (2.5) and (2.7). By the Prokhorov Theorem, $\{\bar{\mu}_t\}_{t>0}$ is weak precompact and thus there is at least one accumulation point $\mu$. By the standard Krylov–Bogolyubov argument $\mu$ is an invariant measure (see [Ar, VF, DZ2] for a detailed statement of these procedures).

Let $t_n, n = 1, 2, \ldots$ be a sequence such that $\mu = w-\lim_{n \to \infty} \bar{\mu}_{t_n}$. Let $B_R$ be the ball of radius $R$ in $H^m_{ul}$ and let $f_{y,R}$ be any bounded continuous function on $L^2_{\delta,y}$ vanishing on $B_R$ (which is a compact set). Since the topologies of $L^2_{\delta,0}$ and of $L^2_{\delta,y}$ are equivalent, this function is continuous on $L^2_{\delta,y}$. Obviously $|\int f_{y,R}(\eta) \bar{\mu}_{t_n}(d\eta)| < \|f\|_\infty \varepsilon(R)$ for all $n$ and $y$, where $\varepsilon(R) \to 0$ as $R \to \infty$. By weak convergence of $\bar{\mu}_{t_n}$ to $\mu$ this also holds for $\mu$ and hence the support of $\mu$ must be contained in $\bigcap_{y \in R} H^m_{\delta,y}$.

We next prove the homogeneity of $\mu$. Let $f \in C_b(H^m_{ul}, C)$ and define the translation operator $T_y$ by $T_y f(u) = f(T_y u)$. We have

$$ \int T_y f(\eta) \mu(d\eta) = \lim_{n \to \infty} \frac{1}{t_n} \int_0^{t_n} \left( \int f(T_y \eta) P\left(\Phi^t_\omega(0) \in d\eta\right) \right) \, dt $$

$$ = \lim_{n \to \infty} \frac{1}{t_n} \int_0^{t_n} \left( \int f(\eta) P\left(T_y(\Phi^t_\omega(0)) \in d\eta\right) \right) \, dt $$

$$ = \lim_{n \to \infty} \frac{1}{t_n} \int_0^{t_n} \left( \int f(\eta) P\left(\Phi^t_{Ty\omega}(T_y(0)) \in d\eta\right) \right) \, dt $$

$$ = \lim_{n \to \infty} \frac{1}{t_n} \int_0^{t_n} \left( \int f(\eta) P\left(\Phi^t_\omega(0) \in d\eta\right) \right) \, dt = \int f(\eta) \mu(d\eta), $$
where we have used the homogeneity of $P$. Since the above holds for all $f$, it proves that $\mu$ is homogeneous and the proof of Theorem 5.1 is finished.

**Remark.** In the above construction of a tight family of measures, we could have considered any homogeneous initial measure $\mu_0$ supported by $\bigcap_{m \geq 0} H^m_{ul}$ instead of $\delta_0$.

### 6 Entropy Estimates

In this section, we define and estimate different notions of entropy for Eq.(2.1). We start with the topological entropy, then the measure-theoretic entropy and finally the $\varepsilon$–entropy. All these quantities are extensive, hence we actually define their spatial densities. We define the spatial density of upper box-counting dimension as well.

To do so we first introduce the basic dynamical setup: let $\Phi_t^\omega (t > 0)$ be the solution semi-flow to Eq.(2.1) for given noise parameter $\omega$ and let $\Theta_t^\omega$ be the shift semi-flow on $\Omega$:

$$\Xi_{\Theta_t^\omega}(x, t) = \Xi_\omega(x, t + \tau) - \Xi_\omega(x, t) .$$

Let next $S^t$ be the semi-flow on $L^2_{\delta,0} \times \Omega$ defined by

$$S^t : L^2_{\delta,0} \times \Omega \rightarrow L^2_{\delta,0} \times \Omega$$

$$(u, \omega) \mapsto (\Phi_t^\omega(u), \Theta_t^\omega(\omega)) .$$

We consider the space $H^m_{ul} (m > d)$ endowed with the (weaker) topology of uniform convergence on the compact $Q \subset \subset \mathbb{R}^d$. By standard embeddings (see (2.6) and (2.7)) bounded sets of $H^m_{ul}$ are compact in $L^\infty(Q)$. Following Crauel et al. [CDF], we define the random attractor $A_\omega$ as follows: Let $B_R$ be the ball of radius $R$, centre 0 in $H^m_{ul}$ and let

$$A_\omega = \bigcup_{R > 0} A(\omega, R),$$

$$A(\omega, R) = \bigcap_{T > 0} \bigcup_{t > T} \Phi_{\Theta_t^\omega}^\omega(B_R) .$$

By the estimates of Section 3, $A_\omega$ is almost surely closed and bounded in $H^m_{ul}$ hence it is compact in $L^\infty(Q)$ for any bounded $Q \subset \mathbb{R}^d$. Moreover the diameter of $A_\omega$ in $H^m_{ul}$ is less than some $R_\omega$ with $P(\omega : R_\omega < \infty) = 1$ and $E(\omega \mapsto R_\omega) < \infty$ (by Theorem 4.1). The following equivariance properties hold (we assume $\theta^t T_x = T_x \theta^t$ for all $(x, t) \in \mathbb{R}^d \times \mathbb{R}^+$):

$$\Phi_t^\omega A_\omega = A_{\theta_t^\omega},$$

$$T_x A_\omega = A_{T_x \theta_t^\omega} ,$$

and it contains the support of any invariant measure for $S^t$. Let next $\mu$ be an invariant measure in the sense of Section 5, namely a stationary measure for the Markov semi-group (5.1). We also assume that $P$ is an invariant measure for $\theta^t$. Then $\mu \times P$ is an invariant measure for the
dynamical system \((S^t, \mathcal{X}, \mathcal{B})\) where \(\mathcal{X} = L^2_{\delta,0} \times \Omega\) and \(\mathcal{B}\) is the associated sigma-algebra. More precisely, one has

\[
\mathbb{E}\left(\omega \mapsto (\Phi^t_\omega)^* \mu\right) = \mu
\]

(which is only a rephrasing of \(P^t_\mu = \mu\), see Eq.\((5.2))\). We introduce the following definitions:

**Definition 6.1.** Let \(\tau > 0, n \in \mathbb{N}, \text{ and } Q \subset \subset \mathbb{R}\). We define a pseudo-metric \(d_{\omega,n,\tau,Q}\) on \(H^{m}_{ul}\) by

\[
d_{\omega,n,\tau,Q}(u, v) = \max_{k=0,\ldots,n-1} \|\Phi^{k\tau}_\omega(u) - \Phi^{k\tau}_\omega(v)\|_{L^\infty(Q)}.
\]

Let \(N_{\omega,n,\tau,Q,\varepsilon}\) be the cardinality of a minimal \((n, \varepsilon)\)–cover of \(A_\omega|Q\) (that is \(N_{\omega,n,\tau,Q,\varepsilon}\) is the least number of open sets whose diameter in the metric \(d_{\omega,n,\tau,Q}\) is at most \(\varepsilon\) and whose union contains \(A_\omega\)).

We define the cube \(Q_L = [-\frac{1}{2}L, \frac{1}{2}L]^d\). We are now able to prove the existence of the spatial density of topological entropy \(h_{top}\) for Eq.\((2.1)):

**Proposition 6.2.** For all \(\tau > 0\) the following limit exists:

\[
h_{top} = \lim_{\varepsilon \to 0} \lim_{L \to \infty} \frac{1}{L^d} \lim_{n \to \infty} \frac{1}{n\tau} \int \log N_{\omega,n,\tau,Q_L,\varepsilon} \mathbf{P}(d\omega),
\]

This limit is independent of \(\tau > 0\).

**Proof.** The proof is similar to the deterministic case treated by Collet and Eckmann in [CE2] and is reproduced in Section 8.

Let \(\mathcal{U} = \{U_1, \ldots, U_k, \ldots\}\) be a countable (or finite) \(\mu\)–measurable partition of \(A_\omega\). For two partitions \(\mathcal{U}\) and \(\mathcal{V}\), we denote their refinement \(\{U_k \cap V_\ell : U_k \in \mathcal{U}, V_\ell \in \mathcal{V}, \mu(U_k \cap V_\ell) > 0\}\) by \(\mathcal{U} \vee \mathcal{V}\). Moreover \(\Phi^{\tau}_\omega^{-1}(\mathcal{U}) = \{\Phi^{\tau}_\omega^{-1}(U_k) : U_k \in \mathcal{U}\}\) is a measurable partition of \(A_{\theta - \tau_\omega}\) whenever \(\mathcal{U}\) is a measurable partition of \(A_\omega\). (Here \(\Phi^{\tau}_\omega^{-1}\) stands for the inverse of \(\Phi^{\tau}_\omega\), namely \(\Phi^{\tau}_\omega^{-1}(x)\) is the set of all pre-images of \(x\).)

**Definition 6.3.** Let \(H_\mu(\mathcal{U})\) and \(H_\mu(\mathcal{U}|\mathcal{V})\) denote the entropy of a partition and the conditional entropy, both relative to a given measure \(\mu\). They are defined as follows

\[
H_\mu(\mathcal{U}) = -\sum_{U \in \mathcal{U}} \mu(U) \log \mu(U),
\]

\[
H_\mu(\mathcal{U}|\mathcal{V}) = -\sum_{U \in \mathcal{U}, V \in \mathcal{V}} \mu(U \cap V) \log \left(\frac{\mu(U \cap V)}{\mu(V)}\right).
\]

We adopt here the convention \(0 \log 0 = 0\) therefore \(0 < H_\mu(\mathcal{U}) \leq \log \text{card} (\mathcal{U})\) (which is possibly infinite for countable \(\mathcal{U}\)). We also choose an arbitrary sequence \(\Sigma_{\omega,\varepsilon}\) of partitions of \(A_\omega\) in sets of diameter at most \(\varepsilon\) in the metric of \(L^\infty(Q_1)\).
The second result in this section is the existence of the spatial density of measure-theoretic entropy $h_\mu$.

**Proposition 6.4.** For all $\tau > 0$ the following limit exists:

$$h_\mu = \lim_{\epsilon \to 0} \lim_{L \to \infty} \frac{1}{L^d} \lim_{n \to \infty} \frac{1}{n\tau} \int H_\mu \left( \bigvee_{x \in \mathbb{Z}^d \cap Q_L} \bigvee_{k=0}^{n-1} \Phi_{\omega,\tau}^{-k\tau} T_x (\Sigma_{\theta_{k\tau} T_x \omega, \epsilon}) \right) P(d\omega).$$  \hspace{1cm} (6.4)

It is independent of $\tau > 0$ and of the particular choice of the sequence of partitions $\Sigma_{\omega, \epsilon}$.

**Proof.** Again, the proof is quite standard, see e.g. [KH, LQ] or Section 9.

We next introduce the notions of $\epsilon$–entropy $\mathcal{H}_\epsilon$ of Kolmogorov and Tikhomirov [KT] and of upper density of dimension $d_{up}$.

**Definition 6.5.** Let $M_{\epsilon, Q, \omega}$ be the least cardinality of an open cover of $A_\omega$ by sets of diameter less than $\epsilon$ in the metric of $L_\infty(Q)$ where $Q$ is compact (we call this an $\epsilon$–cover of $A_\omega|_Q$). Let $\mathcal{H}_\epsilon$ be the Kolmogorov–Tikhomirov $\epsilon$–entropy defined by

$$\mathcal{H}_\epsilon = \lim_{L \to \infty} \frac{1}{L^d} \int \log M_{\epsilon, Q, \omega} L^d P(d\omega),$$

and let $d_{up}(\omega)$ be the upper density of dimension of $A_\omega$:

$$d_{up} = \limsup_{\epsilon \to 0} \frac{\mathcal{H}_\epsilon}{\log \epsilon^{-1}}.$$

The main results of the section are the following inequalities involving the different entropies just defined. Corresponding inequalities in finite dimensional dynamical systems are well-known [KH].

**Theorem 6.6.** There is a $\gamma < \infty$ such that

$$h_\mu \leq h_{top} \leq \gamma d_{up} < \infty.$$  \hspace{1cm} (6.5)

Before giving the proof of Theorem 6.6, we state a lemma which will prove useful later on.

**Lemma 6.7.** There are $C, \gamma$ such that for all (sufficiently large) $L$ and all (sufficiently small) $\epsilon > 0$, if $\|u - v\|_{L_\infty(Q_L)} \leq \epsilon$ then for $t > 0$, $L' = L - C(1 + t) \log 1/\epsilon$, one has

$$\|\Phi_t^{L'}(u) - \Phi_t^{L'}(v)\|_{L_\infty(Q_L)} \leq C e^{\gamma t} \epsilon$$

almost surely.
**Proof.** Let $u_t$ and $v_t$ be two solutions to Eq. (2.1). By Lemma [10.3],

$$\|u_t - v_t\|_{L^2,0} \leq c \gamma t \|u_0 - v_0\|_{L^2,0}$$

and moreover both $\|u_t\|_\infty$ and $\|v_t\|_\infty$ are bounded uniformly in time (see Proposition [4.5]). Let $K_t(\cdot)$ be the convolution kernel associated with the semi-group $\exp(tL)$ (see (4.1)) and let $r_s = u_s - v_s$. By Duhamel’s formula,

$$|r_t(x)| \leq |K_t \ast r_0(x)| + \left| \int_0^t K_{t-s} \ast (G_1(u_s, v_s) r_s + G_2(u_s, v_s) \overline{r}_s)(x) \, ds \right|$$

$$\leq c_1 e^{\gamma t} \varepsilon + \sup_{|x-y|^2 \leq C t \log 1/\varepsilon} |r_0(y)|$$

$$+ \sup_{0 \leq s \leq t} \left( \|G_1(u_s, v_s)\|_\infty + \|G_2(u_s, v_s)\|_\infty \right) \int_0^t |K_{t-s}| \|\phi_{s, x}\| \|r_s\| \, ds$$

$$\leq c_1 e^{\gamma t} \varepsilon + \sup_{|x-y|^2 \leq C t \log 1/\varepsilon} |r_0(y)| + c_2 \sup_{|x-y|^2 \leq C t \log 1/\varepsilon} |r_0(y)| \int_0^t e^{\gamma s} \|G_1(u_s, v_s)\|_2 \, ds$$

$$\leq c_3 (1+t) e^{(1+\gamma)t} \left( 2 \varepsilon + \sup_{|x-y|^2 \leq C t \log 1/\varepsilon} |r_0(y)| \right)$$

$$\leq 4c_3 e^{(2+\gamma)t} \varepsilon,$$

where in the last line we have assumed $|x| \leq \frac{1}{2} L - C(1+t) \log 1/\varepsilon$ (hence $|y| \leq \frac{1}{2} L$) and used the assumption $\sup_{|y| \leq L/2} |r_0(y)| \leq \varepsilon$.

**Proof of Theorem 6.6.** We split Theorem 6.6 into three independent statements, namely each one of the three inequalities in (5.5).

**Proof of $h_{\mu} \leq h_{\text{top}}.$** We follow the most standard proof (originally by Misiurewicz, quoted in [KH]). We modify the partition $\Sigma_{\omega, \varepsilon} = \{\sigma_1, \ldots, \sigma_N\}$ by “shrinking” each element, namely by replacing each $\sigma_j$ by a closed set $U_k$ with $U_k \subset \sigma_k$ and we define $U_0 = A_\omega \setminus \bigcup_{k=1}^N U_k$. We thus obtain a new partition $\mathcal{U}_{\omega, \varepsilon} = \{U_0, \ldots, U_N\}$ and an open cover $\mathcal{V}_{\omega, \varepsilon} = \{U_1 \cup U_0, \ldots, U_N \cup U_0\}$. We assume that the $U_k$ have been chosen such that $\int H_{\mu}(\Sigma_{\omega, \varepsilon} | \mathcal{U}_{\omega, \varepsilon}) \, \mu(dx) < 1$. Remark that

$$\text{card}\left( \bigvee_{x \in \mathbb{Z}^d \cap Q_L} \Phi_{\omega}^{-j \tau} T_{-x}(U_{\theta_j \tau \omega, \varepsilon}) \right) \leq 2^n L^d \text{card}\left( \bigvee_{x \in \mathbb{Z}^d \cap Q_L} \Phi_{\omega}^{-j \tau} T_{-x}(V_{\theta_j \tau \omega, \varepsilon}) \right),$$

and by Definition 6.3

$$H_{\mu} \left( \bigvee_{x \in \mathbb{Z}^d \cap Q_L} \Phi_{\omega}^{-j \tau} T_{-x}(U_{\theta_j \tau \omega, \varepsilon}) \right)$$

$$\leq \log \text{card}\left( \bigvee_{x \in \mathbb{Z}^d \cap Q_L} \Phi_{\omega}^{-j \tau} T_{-x}(U_{\theta_j \tau \omega, \varepsilon}) \right)$$

$$\leq \log \text{card}\left( \bigvee_{x \in \mathbb{Z}^d \cap Q_L} \Phi_{\omega}^{-j \tau} T_{-x}(V_{\theta_j \tau \omega, \varepsilon}) \right) + n L^d \log 2.$$
Consequently
\[
\lim_{L \to \infty} \frac{1}{L^d} \lim_{n \to \infty} \frac{1}{n^T} \int H_\mu \left( \bigvee_{x \in \mathbb{Z}^d \cap Q_L} \bigvee_{j=0}^{n-1} \Phi_{\omega}^{-j\tau} T_{-x} \left( \mathcal{U}_{\theta-j\tau T_\omega} \right) \right) P(d\omega)
\]
\[
\leq \lim_{L \to \infty} \frac{1}{L^d} \lim_{n \to \infty} \frac{1}{n^T} \int \log \text{card} \left( \bigvee_{x \in \mathbb{Z}^d \cap Q_L} \bigvee_{j=0}^{n-1} \Phi_{\omega}^{-j\tau} T_{-x} \left( \mathcal{V}_{\theta-j\tau T_\omega} \right) \right) P(d\omega) + \frac{\log C}{\tau}.
\]
Moreover, the difference between the original partition and the new one is small, namely:
\[
\lim_{n \to \infty} \frac{1}{n^T} \int H_\mu \left( \bigvee_{j=0}^{n-1} \Phi_{\omega}^{-j\tau} \left( \Sigma_{\theta-j\tau \omega, \varepsilon} \right) \right) P(d\omega)
\]
\[
\leq \lim_{n \to \infty} \frac{1}{n^T} \int H_\mu \left( \bigvee_{j=0}^{n-1} \Phi_{\omega}^{-j\tau} \left( \mathcal{U}_{\theta-j\tau T_\omega} \right) \right) P(d\omega) + \int H_\mu \left( \Sigma_{\omega, \varepsilon} | \mathcal{U}_{\omega, \varepsilon} \right) P(d\omega).
\]
Since all the above holds for arbitrarily large \(\tau > 0\) we get
\[
h_\mu \leq \lim_{\varepsilon \to 0} \lim_{L \to \infty} \frac{1}{L^d} \lim_{n \to \infty} \frac{1}{n^T} \int \log \text{card} \left( \bigvee_{x \in \mathbb{Z}^d \cap Q_L} \bigvee_{j=0}^{n-1} \Phi_{\omega}^{-j\tau} T_{-x} \left( \mathcal{V}_{\theta-j\tau T_\omega} \right) \right) P(d\omega) + \frac{\log C}{\tau}.
\]
(6.6)
Let next \(\delta_{\omega, \varepsilon}\) be the Lebesgue number of the cover \(\mathcal{V}_{\omega, \varepsilon}\) (namely the largest \(\delta_{\omega, \varepsilon} > 0\) such that every ball of diameter \(\delta_{\omega, \varepsilon}\) is contained in an element of \(\mathcal{V}_{\omega, \varepsilon}\)). Indeed \(\delta_{\omega, \varepsilon}\) is also the Lebesgue number of \(\bigvee_{j=0}^{n-1} \Phi_{\omega}^{-j\tau} \left( \mathcal{V}_{\theta-j\tau T_\omega} \right)\) with respect to the metric \(d_{\omega, n, \tau, Q_L}\). Hence
\[
\text{card} \left( \bigvee_{x \in \mathbb{Z}^d \cap Q_L} \bigvee_{j=0}^{n-1} \Phi_{\omega}^{-j\tau} T_{-x} \left( \mathcal{V}_{\theta-j\tau T_\omega} \right) \right) \leq M_{\delta_{\omega, \varepsilon}, Q_L, \omega},
\]
and this proves that the r.h.s. of (6.6) is less than \(h_{\text{top}}\).

**Proof of** \(h_{\text{top}} \leq \gamma d_{\text{up}}\). The proof follows [CE2]. Let \(\rho > 0\) be such that \(H_\varepsilon \leq \left( d_{\text{up}} + \rho \right) \log 1/\varepsilon\) for all \(\varepsilon < \varepsilon_0\) and then let \(L_0 = L_0(\varepsilon, \rho)\) be such that all \(L > L_0\) yield
\[
\left| \int \frac{\log M_{\varepsilon, Q_L, \omega}}{L^d} P(d\omega) - H_\varepsilon \right| \leq \rho.
\]
Let \(L' = L + C(T + 1) \log(1/\varepsilon)\) and \(\varepsilon' = C^{-1} \exp\left( -\gamma T \right) \varepsilon\) (see Lemma [6.7]). Let an \(\varepsilon'\)-cover of \(\mathcal{A}_{\omega} |_{Q_{L'}}\) (in the sense of Definition [6.3]) be given. Then it is also a \((T/\tau, \varepsilon)\)-cover (in the sense of Definition [6.1]), hence
\[
N_{\omega, T/\tau, \varepsilon, Q_{L'}, \omega} \leq M_{\varepsilon', Q_{L'}, \omega},
\]
from which follows
\[
    h_{top} = \lim_{\varepsilon \to 0} \lim_{L \to \infty} \frac{1}{L^d} \lim_{T \to \infty} \frac{1}{T} \int \log N_{\omega,T/\tau,\tau,Q_{L,\varepsilon}} P(d\omega)
\]
\[
    = \lim_{\varepsilon \to 0} \lim_{L \to \infty} \frac{1}{L^d} \inf_{T} \frac{1}{T} \int \log N_{\omega,T/\tau,\tau,Q_{L,\varepsilon}} P(d\omega)
\]
\[
    \leq \lim_{\varepsilon \to 0} \lim_{L \to \infty} \frac{1}{T} \int \log M_{\varepsilon',Q_{L,\omega}} P(d\omega)
\]
\[
    \leq \lim_{\varepsilon \to 0} \lim_{L \to \infty} \frac{1}{T} \left((d_{up} + \rho) \log 1/\varepsilon' + \rho\right).
\]

Since \(\log 1/\varepsilon' = \gamma T + \log(C/\varepsilon)\), the limit \(T \to \infty\) and \(\rho \to 0\) leaves only \(\gamma d_{up}\) on the r.h.s. above.

**Proof of** \(d_{up} < \infty\). We want to prove a bound on \(H_\varepsilon\) of the form \(H_\varepsilon \leq C \log 1/\varepsilon\) for small \(\varepsilon > 0\). To do so we use iteratively the following bound:

**Lemma 6.8.** There are \(A, B, C > 0\) such that for all \(L > 0\) and sufficiently small \(\varepsilon > 0\), one has almost surely
\[
    M_{\varepsilon,Q_{L,\omega}} \leq M_{2\varepsilon,Q_{L+C,\theta^{-1}\omega}} A L^d B^{1/\varepsilon^2}. \tag{6.7}
\]

The proof of Lemma 6.8 is postponed to Section 7. Let \(\varepsilon > 0, L > 0\). Remember that there is an \(R_\omega\) such that \(M_{R_\omega,Q_{L,\omega}} = 1\). Let \(T_\omega\) be the smallest integer larger than \((\log 2)^{-1} \log(R_\omega/\varepsilon)\). By iterating \(T_\omega\) times the bound (6.7), we obtain
\[
    M_{\varepsilon,Q_{L,\omega}} \leq \prod_{n=1}^{T_\omega} A^{(L+(n-1)C)^d} B^{1/\varepsilon^2},
\]
hence
\[
    H_\varepsilon = \lim_{L \to \infty} \int \log \frac{M_{\varepsilon,Q_{L,\omega}}}{L^d} P(d\omega) \leq E(\omega \mapsto T_\omega) \log A \leq C(\log 1/\varepsilon + \log E(\omega \mapsto R_\omega)),
\]
(by Jensen’s inequality) or, by Definition 6.5,
\[
    d_{up} = \limsup_{\varepsilon \to 0} \frac{H_\varepsilon}{\log 1/\varepsilon} \leq C,
\]
which is the bound we wanted to prove. With this inequality, the proof of Theorem 6.6 is finished.
We give the proof for the notationally convenient case $d = 1$. Let $u$ and $v$ be two orbits of Eq.~(2.1) with initial conditions $u_0$ and $v_0$ such that $u_0$ and $v_0$ belong to $A_{\omega}$. The difference $r = u - v$ satisfies almost surely the equation

$$\partial_t r = (1 + (1 + i\alpha)\partial_x^2) r + G_1(u, v)r + G_2(u, v)r,$$

(7.1)

where we have used the notation of Eq.~(10.1).

Let $\chi(x)$ be a smooth and monotone function satisfying $\chi(x) = 1$ if $x \leq 1$ and $\chi(x) = 0$ if $x \geq 2$. We decompose the kernel of $\exp(t\mathcal{L})$ into a low frequency part and a high frequency part:

$$K_t(-)(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{ipx + t(1 - (1 + i\alpha)p^2)} \chi(|p/p^*|) \, dp,$$

$$K_t(+)(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{ipx + t(1 - (1 + i\alpha)p^2)} (1 - \chi(|p/p^*|)) \, dp,$$

where $p^* > 4$ is a sufficiently large real number. We decompose the solutions $r_t(x)$ to Eq.~(7.1) accordingly:

$$r_t(x) = r_t(-)(x) + r_t(+)(x),$$

$$r_t(-)(x) = (K_t(-) * r_0)(x) + \int_0^t (K_{t-s}(-) * (G_1(u_s, v_s)r_s + G_2(u_s, v_s)r_s))(x) \, ds,$$

$$r_t(+)(x) = (K_t(+)) * r_0)(x) + \int_0^t (K_{t-s}(-) * (G_1(u_s, v_s)r_s + G_2(u_s, v_s)r_s))(x) \, ds,$$

The kernels $K_t(-)$ and $K_t(+)$ have some regularity and decay properties that we next describe: let the Bernstein class $B_{R,k}$ be the following set of functions:

$$B_{R,k} \equiv \{ f \in L^\infty : f \text{ extends to an entire function}, |f(z)| \leq Re^{k|\Im z|} \}.$$

We have

Lemma 7.1. For all $p^* > 4$, $t > \frac{1}{2}$, $f \in L^\infty$, $K_t(-) * f$ is in $B_{R,2p^*}$ with $R \leq 2C_0\|f\|_\infty$. Moreover, for all $n \in \mathbb{N}$, there is a $C_n > 0$ such that

$$|K_t(-)(x)| \leq \frac{C_n}{\sqrt{t}}(1 + x^2/t)^{-n},$$

$$|K_t(+)(x)| \leq \frac{C_n}{\sqrt{t}}e^{-(p^*)^2t/2}(1 + x^2/t)^{-n}.$$

The proof of Lemma 7.1 is omitted, see [CE2, Ro].
Pick a $2\varepsilon$–cover of $A_\omega|_{Q_{L+C(\varepsilon)}}$ (which exists a.s. by compactness, see Definition 6.5) and let $u$ and $v$ belong to one of its elements. Then $r_0 = u - v$ satisfies $|r_0(x)| \leq 2\varepsilon$ for $|x| \leq \frac{1}{2}(L+C(\varepsilon))$. Define

$$\xi^{(n)}_y(x) = \frac{1}{(1 + (x-y)^2)^{n/2}}.$$

Remark that Lemma 10.3 also holds with $\varphi_y$ replaced by $\xi^{(n)}_y$ $(n \geq 2)$. Moreover by reproducing the proof of Lemma 6.7 using the bounds from Lemma 7.1 we obtain (for $|x| \leq L/2$):

$$|r_1^{(-)}(x)| \leq |K_1^{(-)} * r_0(x)| + C \int_0^1 \|K_1^{(-)} / \sqrt{s_0^{(n)}} || \sqrt{\xi^{(n)}_y r_s} \|_2 \leq C\varepsilon + 2C\varepsilon \int_0^1 \frac{C_n}{\sqrt{1-s}} e^{\gamma s} \, ds \leq A\varepsilon,$$

where $A$ depends on $n$ but not on $p^*$ and

$$|r_1^{(+)}(x)| \leq |K_1^{(+)} * r_0(x)| + C \int_0^1 \|K_1^{(+)} / \sqrt{s_0^{(n)}} || \sqrt{\xi^{(n)}_y r_s} \|_2 \leq e^{-\frac{(p^*)^2}{2}} + 2\varepsilon \int_0^1 \frac{C_n e^{-\frac{(p^*)^2(1-s)/2}}}{\sqrt{1-s}} e^{\gamma s} \, ds \leq B(p^*)\varepsilon,$$

where $B(p^*) \to 0$ as $p^* \to \infty$. We choose $p^*$ so large that $B(p^*) < \frac{1}{2}$.

We next use a result of Cartwright (see [KT], Eq.(191)): for all $f$ in the Bernstein class $B_{R,2p^*}$ (see (7.2)), the following identity holds:

$$f(x) = \frac{\sin(8p^* x)}{32(p^*)^2} \sum_{n=-\infty}^{\infty} (-1)^n f(x_n) \frac{\sin(4p^*(x-x_n))}{(x-x_n)^2},$$

where $x_n = \frac{np^*}{2\pi}$. Let $f, g$ be in $B_{R,2p^*}$. A simple application of Eq.(7.5) shows that

$$\|f - g\|_{L^\infty(Q_L)} \leq C \sup_{|n| \leq [4p^* L/\pi] + 4Cp^*/(\varepsilon \pi)} |f(x_n) - g(x_n)| + \frac{1}{4} \varepsilon.$$

Hence, among all the functions in $B_{R,2p^*}$ that are bounded by $A\varepsilon$ in $[-\frac{1}{2}L, \frac{1}{2}L]$ (by (7.3), $r_1^{(-)}$ is such a function), at most $(4A)^{Cp^* L}(4R_{\omega}/\varepsilon)^{Cp^*/\varepsilon}$ of them are $\varepsilon/2$–separated on $Q_L$. By taking a ball of diameter $\varepsilon$ around each of them, and repeating the operation for each element of the original $2\varepsilon$–cover, we get an $\varepsilon$–cover of $\Phi^1_\epsilon(A_\omega)|_{Q_L} = A^1_{\theta^1,\omega}|_{Q_L}$. The number of elements in this cover is at most

$$(4A)^{Cp^* L}(4R_{\omega}/\varepsilon)^{Cp^*/\varepsilon} M_{2\varepsilon,Q_L+\varepsilon,\omega}.$$

The proof of Lemma 6.8 is complete. \qed
8 Proof of Proposition 6.2

We follow Collet and Eckmann’s proof \[\text{[CE2]},\] which is itself an adaptation of standard proofs of existence of the topological entropy, see e.g. \[\text{[KH]}\] and references therein. The proof of Proposition 6.2 is based on the following inequalities:

**Lemma 8.1.** For all compacts \(Q, Q',\) all \(m, n \in \mathbb{N}\) and \(\varepsilon > \varepsilon' > 0\) one has

\[
N_{\omega, n, \tau, Q, \varepsilon} \leq N_{\omega, n, \tau, Q, \varepsilon'}, \quad \tag{8.1}
\]
\[
N_{\omega, n, \tau, Q, \varepsilon} \leq N_{\omega, n, \tau, Q, \varepsilon} N_{\omega, n, \tau, Q', \varepsilon}, \quad \tag{8.2}
\]
\[
N_{\omega, n+m, \tau, Q, \varepsilon} \leq N_{\omega, n, \tau, Q, \varepsilon} N_{\theta \tau \omega, m, \tau, Q, \varepsilon}, \quad \tag{8.3}
\]

Furthermore for any \(\tau' < \tau\) the following inequalities hold:

\[
N_{\omega, n, \tau', Q, L, \varepsilon} \leq N_{\omega, n, \tau, Q, \varepsilon} f(L) \leq N_{\omega, n, \tau', Q, f(L)} g(\varepsilon), \quad \tag{8.4}
\]

where \(f(L) = L + C(\tau + 1) \log \varepsilon^{-1}\) and \(g(\varepsilon) = c \exp(-\gamma \tau) \varepsilon\) with \(C, c, \gamma\) some constants.

**Proof of Lemma 8.1.** The inequality (8.1) is obvious from the definitions. We prove (8.2) by making the observation that if \(\{A_1, \ldots, A_N\}\) is an \((n, \varepsilon)\)-cover of \(A_\omega|_Q\) and \(\{B_1, \ldots, B_M\}\) an \((n, \varepsilon)\)-cover of \(A_\omega|_{Q'}\), then \(\{A_j \cap B_k : j = 1, \ldots, N, k = 1, \ldots, M\}\) is an \((n, \varepsilon)\)-cover of \(A_\omega|_{Q \cup Q'}\).

Similarly if \(\{A_1, \ldots, A_N\}\) is an \((n, \varepsilon)\)-cover of \(A_\omega|_Q\) and \(\{B_1, \ldots, B_M\}\) an \((m, \varepsilon)\)-cover of \(A_{\theta \tau \omega}|_Q\), then \(\{A_j \cap \Phi_{\omega}^{n \tau} B_k : j = 1, \ldots, N, k = 1, \ldots, M\}\) is an \((m+n, \varepsilon)\)-cover of \(A_\omega|_Q\) which proves (8.3).

The inequality (8.4) follows immediately from Lemma 6.7, since if \(D\) is a set of diameter \(g(\varepsilon)\) in the metric \(d_{\omega, n, \tau, Q, f(L)}\) then \(D\) is a set of diameter at most \(\varepsilon\) in the metric \(d_{\omega, n, \tau', Q, L}\).

**Remark.** The topology of \(L^\infty(Q)\) is a simplifying choice (as far as Eq. (8.2) is concerned), but \[\text{[CE3]}\] have demonstrated that other topologies can be used as well.
9 Proof of Proposition 6.4

This proof is, like the proof of Proposition 6.2, based on subadditive bounds. We use well-known properties of the function $H_{\mu}(\cdot)$, see [KH], Chapter 4.3 (in particular Proposition 4.3.3). We recall that $x \mapsto -x \log x$ is concave, hence for any partition $\mathcal{U}$ and any $t > 0$, the following holds:

$$\int H_{\mu}(\Phi_{\omega}^{-t}(\mathcal{U})) \mathbb{P}(d\omega) \leq H_{\mu}\left(\int \Phi_{\omega}^{-t}(\mathcal{U}) \mathbb{P}(d\omega)\right) = H_{\mu}(\mathcal{U})$$

where we have used Eq. (6.2). We thus have

$$\int H_{\mu}\left(\bigvee_{k=0}^{n+m-1} \Phi_{\omega}^{-k\tau}(\Sigma_{\theta^{k\tau}\omega,\varepsilon})\right) \mathbb{P}(d\omega)$$

$$= \int H_{\mu}\left(\bigvee_{k=0}^{n-1} \Phi_{\omega}^{-k\tau}(\Sigma_{\theta^{k\tau}\omega,\varepsilon})\right) \mathbb{P}(d\omega)$$

$$+ \int H_{\mu}\left(\bigvee_{k=n}^{n+m-1} \Phi_{\omega}^{-k\tau}(\Sigma_{\theta^{k\tau}\omega,\varepsilon})\right) \mathbb{P}(d\omega)$$

$$\leq \int H_{\mu}\left(\bigvee_{k=0}^{n-1} \Phi_{\omega}^{-k\tau}(\Sigma_{\theta^{k\tau}\omega,\varepsilon})\right) \mathbb{P}(d\omega) + \int H_{\mu}\left(\bigvee_{k=0}^{m-1} \Phi_{\omega}^{-k\tau}(\Sigma_{\theta^{(k+n)\tau}\omega,\varepsilon})\right) \mathbb{P}(d\omega)$$

$$\leq \int H_{\mu}\left(\bigvee_{k=0}^{n-1} \Phi_{\omega}^{-k\tau}(\Sigma_{\theta^{k\tau}\omega,\varepsilon})\right) \mathbb{P}(d\omega) + \int H_{\mu}\left(\bigvee_{k=0}^{m-1} \Phi_{\omega}^{-k\tau}(\Sigma_{\theta^{k\tau}\omega,\varepsilon})\right) \mathbb{P}(d\omega)$$

$$\leq \int H_{\mu}\left(\bigvee_{k=0}^{n-1} \Phi_{\omega}^{-k\tau}(\Sigma_{\theta^{k\tau}\omega,\varepsilon})\right) \mathbb{P}(d\omega) + \int H_{\mu}\left(\bigvee_{k=0}^{m-1} \Phi_{\omega}^{-k\tau}(\Sigma_{\theta^{k\tau}\omega,\varepsilon})\right) \mathbb{P}(d\omega)$$

nearly subadditivity in the time variable. We can prove subadditivity in the space variable in a similar way. Thus the first two limits in Eq. (6.4) exist. These limits are monotonically increasing as $\varepsilon \to 0$, hence the third limit is well-defined.

We next prove that the limit is independent of the choice of $\Sigma_{\omega,\varepsilon}$: let $\Sigma_{\omega,\varepsilon}$ and $\widetilde{\Sigma}_{\omega,\varepsilon}$ be two different sequences, we get (by the Rokhlin inequality)

$$\left| \lim_{L \to \infty} \frac{1}{L^d} \lim_{n \to \infty} \frac{1}{n^T} H_{\mu}\left(\bigvee_{x \in \mathbb{Z}^d \cap Q_L}^{n-1} \Phi_{\omega}^{-k\tau} T_{-x}(\Sigma_{\theta^{k\tau}\omega,\varepsilon})\right) \right|$$

$$- \lim_{L \to \infty} \frac{1}{L^d} \lim_{n \to \infty} \frac{1}{n^T} H_{\mu}\left(\bigvee_{x \in \mathbb{Z}^d \cap Q_L}^{n-1} \Phi_{\omega}^{-k\tau} T_{-x}(\widetilde{\Sigma}_{\theta^{k\tau}\omega,\varepsilon})\right) \right|$$

$$\leq H_{\mu}(\Sigma_{\omega,\varepsilon}|\widetilde{\Sigma}_{\omega,\varepsilon}) + H_{\mu}(\widetilde{\Sigma}_{\omega,\varepsilon}|\Sigma_{\omega,\varepsilon})$$

and the r.h.s. above vanishes as $\varepsilon \to 0$ since these sequences generate the whole sigma-algebra of $\mathcal{A}_{\omega}$ in this limit.
We prove that Eq. (6.4) is independent of $\tau$ by using Lemma 6.7 and an argument similar to the one used in Section 8.

10 Uniqueness of Solutions

In this section, we use the Contraction Mapping Principle to prove uniqueness of solutions to Eq. (4.5) as well as estimates on the stopping times Eq. (4.4) (along the lines of Da Prato and Zabczyk, [DZ1] Chapter 7). We define a Banach space $B_{p,K,T}$ of complex-valued predictable processes $u$ on the time interval $[0,T]$ with norm defined by

$$
\|u\|_p = \left( \sup_{0 \leq t \leq T} E(e^{-Kt}\|u_t\|_\infty^p) \right)^{1/p}.
$$

We prove existence and uniqueness of solutions to Eq. (4.3) in $B_{p,K,T}$:

Lemma 10.1. Let $T > 0$, $p > 1$, and $M > 1$. For sufficiently large $K$, there exists a unique solution $u_t \in B_{p,K,T}$ to Eq. (4.3) with initial data $u_0$.

Proof. We define the map $\mathcal{F} : B_{p,K,T} \to B_{p,K,T}$ by (see Eq. (4.3))

$$
\mathcal{F}(X)_t = e^{t\mathcal{L}}u_0 + \int_0^t e^{(t-s)\mathcal{L}}P_M(|X_s|)|X_s|^{2q}X_s \, ds + \int_0^t e^{(t-s)\mathcal{L}}\xi_s \, dw_s.
$$

If $E(\|u_0\|_\infty^p) < \infty$ then obviously $\mathcal{F}$ maps $B_{p,K,T}$ into itself. We define

$$
\mathcal{N}(|x|^2) = - (b + i\beta)P_M(|x|)|x|^{2q},
\mathcal{G}_1(x,y) = \frac{1}{2} \left( \mathcal{N}(|x|^2) + \mathcal{N}(|y|^2) + (|x|^2 + |y|^2) \int_0^1 \mathcal{N}'(t|x|^2 + (1-t)|y|^2) \, dt \right),
\mathcal{G}_2(x,y) = xy \int_0^1 \mathcal{N}'(t|x|^2 + (1-t)|y|^2) \, dt.
$$

If $X$ and $Y$ are arbitrary elements of $B_{p,K,T}$, then

$$
\|\mathcal{F}(X) - \mathcal{F}(Y)\|_p^p = \sup_{0 \leq t \leq T} E \left( \int_0^t e^{(t-s)(\mathcal{L}-K)} \left( \mathcal{G}_1(X_s, Y_s)e^{-Ks}(X_s - Y_s) + \mathcal{G}_2(X_s, Y_s)e^{-Ks}(X_s - Y_s) \right) \, ds \right) \| |X_s - Y_s| \|_\infty^p \leq CM^{2qp}(K-c)^{-p}\|X - Y\|_p^p.
$$

The map $\mathcal{F}$ is thus a contraction on $B_{p,K,T}$ if $K > C'M^{2q}$. This proves the existence and the uniqueness of a solution $u_t$ to Eq. (4.3).

To be able to treat solutions to Eq. (4.5) as solutions to Eq. (4.2) for some time, we use the following bounds on the stopping times $\tau(R)$ defined by Eq. (4.4):
Lemma 10.2. There is a $C > 0$ such that the following holds almost surely for all $R > 1$:

$$\tau(R) \geq CR^{-2q} \log R.$$  

Proof. This follows immediately from Lemma [10.1] since we can take any $M > R$.

We next show that solutions of Eq. (2.1) are also uniquely defined on $L^2_{\delta,y}$, using that bounded functions form a dense subset.

Lemma 10.3. The semi-flow $\Phi^t_\omega$ extends almost surely to a bounded continuous semi-flow on $L^2_{\delta,y}$ for any $\delta > 0$ and $y \in \mathbb{R}^d$.

Proof. We apply the non-propagation estimate of Ginibre and Velo [GV1]. Let $u_0$ and $v_0$ be two functions in $L^2_{\delta,y}$ and denote the corresponding solutions to Eq. (2.1) by $u_t$ and $v_t$. Their difference $u_t - v_t$ satisfies (almost surely) the following inequality:

$$\frac{1}{2} \partial_t \| \sqrt{\varphi_{\delta,y}} (u_t - v_t) \|^2 \leq (1 + \frac{1}{2} \sqrt{1 + \alpha^2}) \| \sqrt{\varphi_{\delta,y}} (u_t - v_t) \|^2 - \text{Re} (1 + i\beta) \int \varphi_{\delta,y} (\overline{u_t} - \overline{v_t}) (|u_t|^{2q} u_t - |v_t|^{2q} v_t).$$

By [GV1] (Proposition 3.1), Hypothesis 2.1 implies that the last term above is negative. We thus get an estimate of the form

$$\| u_t - v_t \|_{L^2_{\delta,y}} \leq \exp(\alpha t) \| u_0 - v_0 \|_{L^2_{\delta,y}}$$

This and Lemma 4.3 prove that $\Phi^t_\omega$ is uniformly bounded and continuous on $L^2_{\delta,y}$ for any $\delta > 0$ and $y \in \mathbb{R}^d$ if we define $u_t = \lim_{n \to \infty} u_t^{(n)}$ where $u_0^{(n)}$ is a Cauchy sequence of bounded functions approaching $u_0$.

11 Compact Embedding for Local Spaces

In this section, we give a proof of Relation (2.7) which is a trivial adaptation of [Ad], Theorem 6.53, p.174. More precisely we prove the embedding (2.7) to be Hilbert–Schmidt. Let $\{e_n\}_{n \in \mathbb{N}}$ be a complete orthonormal basis of $H^{m+k}_{\delta,y}$. Let $\{Q_n\}_{n \in \mathbb{N}}$ be a countable cover of $\mathbb{R}^d$ by balls of radius 1. Let $x \in Q_n$, let $\alpha \leq m$ and define the bounded linear operator $D^\alpha_x$ on $H^{m+k}_{\delta,y}$ by

$$D^\alpha_x(u) = \nabla^\alpha u(x).$$

Its norm is (by Sobolev embedding) bounded by

$$\| D^\alpha_x(u) \|^2_{H^{m+k}_{\delta,y}} \leq \max_{0 \leq \alpha \leq m} \sup_{x \in Q_n} |\nabla^\alpha u(x)|^2 \leq \frac{C}{\inf_{x \in Q_n} \varphi_{\delta,y}(x)} \| u \|^2_{H^{m+k}_{\delta,y}}.$$

By Riesz’ Lemma, $D^\alpha_x(\cdot) = (v^\alpha_x, \cdot)_{H^{m+k}_{\delta,y}}$ for some vector $v^\alpha_x$ and

$$\sum_{n=1}^{\infty} |\nabla^\alpha e_n(x)|^2 = \sum_{n=1}^{\infty} |(e_n, v^\alpha_x)_{H^{m+k}_{\delta,y}}|^2 = \| v^\alpha_x \|^2_{H^{m+k}_{\delta,y}}.$$
Thus the Hilbert–Schmidt norm of the embedding map is
\[
\sum_{n=1}^{\infty} \|e_n\|_{H^m_{\delta',y}}^2 = \sum_{\alpha \leq m} \int_{\mathbb{R}^d} \|v_\alpha\|_{H^{m+k}_{\delta',y}}^2 \, dx \leq m \sum_{n=1}^{\infty} \int_{Q_n} \frac{C\varphi_{\delta',y}(x)}{\inf_{z \in Q_n} \varphi_{\delta,y}(z)} \, dx,
\]
which is finite whenever \(\delta' > \delta\).

\[\square\]

12 Proof of Lemma 4.6

The proof can be found in \([BGO, Mi]\) and is summarised below. We decompose the plane into countably many sets \(Q(m, n)\) of unit area and use the bounds \(\varphi_{\delta,y}(x) \leq \exp(-\delta|x - y|) \leq e\varphi_{\delta,y}(x)\). For simplicity we assume \(\delta = 1\) and we drop it from our notation (if Lemma 4.6 is true for \(\delta = 1\) then it is true for all \(\delta > 0\) by scaling, possibly with different constants). We simply write \(\int_D f\) for \(\int_D f(x) \, dx\) for \(D \subset \mathbb{R}^2\). We have

\[
\int_{\mathbb{R}^2} \varphi_y |\Delta(|f|^{2q} f)| \Delta f| \leq C \sum_{m,n} e^{-|n|} \int_{Q(m,n)} |\Delta f||f|^{2q-1}(|f||\Delta f| + |\nabla f|^2),
\]

(12.1)

where \(\bigcup_m Q(m, n) \supset \{x \in \mathbb{R}^2 : n - \frac{1}{2} \leq |x - y| \leq n + \frac{1}{2}\}\). We estimate each summand using Hölder and Gagliardo–Nirenberg inequalities. For any \(p, r\) with \(p^{-1} + r^{-1} = 1\) and in particular for \(r = 1 + 1/q\) and \(p = 1 + q\), we get:

\[
\int_{Q(m,n)} |\Delta f||f|^{2q-1}(|f||\Delta f| + |\nabla f|^2)
\]

\[
\leq c_1 |\Delta f|_{2p} ||f|^{2q}_{2pq/(p-1)} |\Delta f|_{2p} + ||f|^{2q-1}_{2pq/(p-1)} ||\nabla f|^2_{4pq/(p+q-1)}
\]

\[
\leq c_2 |\Delta f|_{2p} ||f|^{2q}_{2pq/(p-1)} |\Delta f|_{2p} + ||f|^{2q-1}_{2pq/(p-1)} ||f|^{1/2}_{2pq/(p-1)} |\Delta f|^{1/2}_{2p})^2
\]

\[
= c_3 |\Delta f|_{2p}^2 |f|^{2q}_{2q}
\]

\[
\leq c_4 |\nabla^3 f|^2_{2/(2q+2)/(2q+3)} ||f||^{2q+1/(2q+3)}_{2q+1}
\]

\[
\leq K^{-1} |\nabla^3 f|^2_{2} + c_5 K ||f||^{4q^2+6q+2}_{2q+1}.
\]

By summing up all contribution to (12.1) we arrive at

\[
\int_{\mathbb{R}^2} \varphi_y |\Delta(|f|^{2q} f)| \Delta f|
\]

\[
\leq CK^{-1} \sum_{m,n} e^{-|n|} \int_{Q(m,n)} |\nabla^3 f|^2 + C' K \sum_{m,n} e^{-|n|} \left( \int_{Q(m,n)} |f|^{2(q+1)} \right)^\eta
\]

\[
\leq \tilde{C}K^{-1} \int_{\mathbb{R}^2} \varphi_y |\nabla^3 f|^2 + C'' K \sum_{n} n e^{-|n|} \left( \sup_y \int_{\mathbb{R}^2} \varphi_y |f|^{2(q+1)} \right)^\eta
\]

\[
= \tilde{C}K^{-1} \int_{\mathbb{R}^2} \varphi_y |\nabla^3 f|^2 + C'' K \left( \sup_y \int_{\mathbb{R}^2} \varphi_y |f|^{2(q+1)} \right)^\eta,
\]

which proves Lemma 4.6.
