Abstract

The Global Emissions Initiative (GEIA) storages and offers global datasets of emission inventories developed in the last 30 years. One of the most recently updated global datasets covering anthropogenic source emissions is the Copernicus Atmosphere Monitoring Service (CAMS). This study applied the NetCDF Command Operator (NCO) software to preprocess the anthropogenic sources included in the CAMS datasets and converted those files as an input in the Sparse Matrix Operator Kernel Emissions (SMOKE) model for future air quality modeling. As a result, six steps were applied to obtain the required file format. The case of the Central coast in Chile was analyzed to compare the global database and the official reports for the on-road transport sector. As a result, some differences were shown in the most populated locations of the domain of analysis. The rest of the zones registered similar values. The methodology exposed in this report could be applied in any other region of the planet for air quality modeling studies. The development of global datasets like CAMS is useful for hemispheric analysis and it could bring an estimation on the mesoscale scale. It represents an opportunity for those locations without official reports of non-updated data.

Introduction

The most accurate and absolute air emission inventory estimation is crucial to achieving an air quality simulation [1]. Some countries have been established datasets with this information at a high level of detail, improving and enhancing studies for better environmental policy at local, regional and national levels. Unfortunately, there are many regions with unclear or undefined emission inventory, avoiding air quality models in those locations.

In the last 30 years, various global datasets of emission inventories have been developed for different sources and covering specific periods of analysis. Today, the Global Emissions Initiative (GEIA) storages and offers those datasets. It represents an opportunity for those locations without official reports of non-updated data. More information about the organization's mission and goals can be found on its website (http://www.geiacenter.org). One of the most recently updated global datasets covering anthropogenic source emissions is the Copernicus Atmosphere Monitoring Service (CAMS) developed by the European Centre for Medium-Range Weather Forecasts (ECMWF) on behalf of the European Commission.

CAMS datasets is a compiled emission inventory developed for the years 2000–2020 for many atmospheric compounds. The anthropogenic sources include 12 sectors, and the spatial resolution is 0.1°. The methodology of the emission inventory estimation can be accessed in a published report [2]. The files of CAMS datasets are hosted on the GEIA website. Also, they are processed with the Network Common Data Form (NetCDF) format and are available upon user request. The instruction for download the desired files are sent by email to the registered user.

Until today, there are no published reports with the application of CAMS datasets as an input on air quality models. One of the main causes could be the lack of information about its processing. The
The purpose of this study is to expose a methodology for CAMs datasets processing and convert those files as an input in the Sparse Matrix Operator Kerner Emissions (SMOKE) model [3]. SMOKE is the preprocessor of the emission inventory for air quality models like CMAQ [4] and CAMx [5]. The steps reported could be applied in future air quality modeling studies on regions where the emission inventory is not defined or not developed at all.

Methodology

The CAMS-GLOB-ANT datasets contain monthly emissions for anthropogenic sources. In this study, the on-road transport (tro) sector was analyzed. All files were processed using the NetCDF Command Operator (NCO) software. NCO is designed for analysis and modification of gridded data stored in NetCDF format [6]. This software was released in 2008, and many research studies have been developed by using this tool since then. NCO has different types of commands for reading, writing, interpolating and averaging [7].

In this study, the first step was the extraction of the emissions for one month, as shown in Table 1. If the user downloads more than one month in a unique file, the first month’s counter must start at zero. For example, in this study, the total emissions for 2018 were downloaded, so the counter for August emissions was the number seven. The counter for the rest of the monthly emissions must be according to the item in an ordered list. While the user downloads one file with one-month data, this step is not needed.

| Step | command | Example |
|------|---------|---------|
| 1    | ncks    | ncks -O -d time,"number related to the month of analysis" CAMS_file fileSTEP1_out |
| 2    | ncwa    | ncwa -O -a time fileSTEP1_out fileSTEP2_out |
| 3    | ncks    | ncks -C -O -x -v time fileSTEP2_out fileSTEP3_out |
| 4    | ncks    | ncks -O -3 fileSTEP3_out fileSTEP4_out |
| 5    | ncks    | ncks -O -v tro --msa -d lon,0.,180. -d lon,-180.,0. fileSTEP4_out fileSTEP5_out |
| 6    | ncks    | ncap2 -O -s 'where(lon < 0) lon = lon + 360' fileSTEP6_out file_for_SMOKE.nc |

After the extraction of the desired monthly data, the file format must be modified. The second step deletes the attribute named "time" in the extracted file on step 1. Next, the variable "time" is also deleted in step 3. SMOKE does not read gridded emission inventory data with that attribute and variable [3], and that is why they must be extracted in steps 2 and 3. The next step (4) changes the file format to NetCDF type 3, which is a SMOKE requirement for this gridded emission data. Steps 2–4 are also mentioned in the methodology reported by Pino-Cortés et al. [8].
Finally, steps 5 and 6 modify the attribute "longitude". The original file of CAMS-GLOB-ANT datasets has the longitude ordered from 180 ° to -180 °, and it is observed in Fig. 1 (upside). However, this attribute must be relocated from 0 ° to 360 °, being the 0 ° the longitude with the original column. Figure 1 (downside) shows the modification of step 6. The output file from step 6 has all the requirements to input into the SMOKE model. All steps exposed in Table 1 could be replicated for all sectors included in the CAMS-GLOB-ANT datasets.

**Case Study Results And Discussions**

The Puchuncavi-Quintero-Concon industrial complex is located on the Central coast of Chile in the communes with the same names. Currently, this area is saturated by particulate matter, although there is also monitoring of sulfur dioxide (SO₂), ozone (O₃), nitrogen dioxide (NO₂) and carbon monoxide (CO) in different air quality monitoring stations. In this industrial zone, the inventory of emissions from industrial sources is available and detailed as an individual point source at the Chilean Pollutant Release and Transfer Registers (PRTR) website (https://retc.mma.gob.cl/). Otherwise, the annual transport emissions are reported at the commune level, but it is limited to specific areas and there is not available gridded georeferenced data. This is the main limitation for the evaluation of this source emission in studies of air quality.

This study applied the CAMS-GLOB-ANT datasets for the identification and analysis of the emissions from the transport sector. The Weather Research and Forecast (WRF) model version 4.1.2 was used to create a domain of analysis with 73 x 73 grid cells and 1 km of horizontal resolution. WRF model was run for 1 hour, and the output file was processed in the computational module Meteorology-Chemistry Interface Processor (MCIP) [9]. MCIP creates four files with the georeferenced information required by the SMOKE model and reduces 3 grid cells for each side of the domain, generating a new domain with 70 x 70 grid cells in this study.

The monthly processed files as described in the previous section were input into SMOKE as gridded data.

The spatial distribution of the emissions processed in SMOKE is shown in Fig. 2. The letters represent the communes’ location in the domain of analysis. The gridded cells positioned in the ocean are explained by the resolution of the CAMS datasets files. However, the emissions processed in SMOKE can be considered acceptable and a preliminary estimation for future air quality modeling.

One of the main uncertainties for emission inventory simulation is the temporal profile of the emissions. The SMOKE output files bring the monthly fraction of transport emissions, as shown in Fig. 2. In this case, three different registries were obtained for different communes in the zone of analysis.

The highest emissions occurred during August 2018 for all communes. In contrast, the lowest fractions were observed in January, February and July, when the holiday season is present in Chile. The temporal profile obtained using CAMS datasets is reasonable except for Viña del Mar and Valparaiso. These communes received many tourists during holidays every year, impacting the transport sector and
increasing the traffic on the urban streets. In January and February, the monthly profile must be higher than the rest of the year. The information shown in Fig. 3 could help future studies of emission inventories about this anthropogenic source in Chile.

Table 2
Comparison of the annual emissions from CAMS datasets and official report in Chile.

| Commune     | Sulfur dioxide | Carbon Monoxide | Methane |
|-------------|----------------|-----------------|---------|
|             | CAMS  | Official report| CAMS  | Official report| CAMS  | Official report|
| Valparaiso  | 0.439 | 3.392           | 2260  | 4057           | 4.610 | 24.800         |
| Viña del Mar| 1.148 | 4.997           | 5713  | 5895           | 11.757| 36.475         |
| Quilpue     | 1.263 | 1.530           | 4466  | 2000           | 8.925 | 10.918         |
| Villa Alemana| 1.110 | 1.173           | 3674  | 1256           | 7.470 | 7.867          |
| Concon      | 1.036 | 0.627           | 2154  | 1353           | 4.437 | 5.968          |
| Quintero    | 0.355 | 0.142           | 961   | 217            | 1.876 | 0.622          |
| Puchuncavi  | 0.489 | -               | 1522  | -              | 3.170 | -              |

The CAMS datasets registries were compared to the official report from PRTR in Chile [10]. As shown in Table 2, most of the emissions recorded in Valparaiso and Viña del Mar from the global database are lower than the government estimation in Chile. Both communes are the most populated in the region and receive many flotant people every day. Otherwise, the records for Quilpue, Villa Alemana and Concon, are comparable, except for CO in Quilpue, where the CAMS dataset registered more than twice the official report. These zones are considered housing regions and their emissions from the transport sector are lower than reported in Valparaiso and Viña del Mar. Finally, the emissions recorded in Quintero from the global database are 3 times higher than the national registries. It could be explained due to the industrial sector is the most current activity in this commune. Finally, there are not official emission records for the Puchuncavi commune and the values from the CAMS dataset could be helpful for the air quality modeling in this zone. It is remarkable to distinguish that the emissions from the official report are estimated using mobile models.

Summary

The methodology exposed in this report could be applied in any other region of the planet. This study applied NCO commands available for the preprocessing of the CAMS datasets files. As a result, the required file format is obtained to input gridded data into the SMOKE model. The emissions and temporal profile registered in CAMS datasets must be compared to official reports of transport sectors. More realistic and accurate emission inventory must benefit the research community for more air quality modeling studies in zones where this information is scarce or undefined. The development of global
datasets like CAMS is useful for hemispheric analysis and it could bring an estimation on the mesoscale scale.
