Nickel phosphide (Ni-P) films as a catalytic cathode for the hydrogen evolution reaction (HER) of a water splitting were fabricated by a pulse-reverse electrodeposition technique. The electrochemical behaviors for the electrodeposition of Ni-P were investigated by the characterization of peaks in a cyclic voltammogram. The composition of the electrodeposited Ni-P alloys was controlled by adjusting duty cycles of the pulse-reverse electrodeposition. The HER electrocatalytic properties of the Ni-P electrodeposits with an amorphous phase as a function of phosphorous contents existing in Ni-P were electrochemically characterized by the analysis of overpotentials, Tafel slopes, and electrochemical impedance spectrometry. Additionally, the elemental Ni-embedded crystalline Ni₃P was prepared by an annealing process with the amorphous Ni₆₉P₃₁ electrodeposit with high contents of phosphorus. The crystalline structure with Ni inclusions in the matrix of Ni₃P was formed by the precipitation of excess Ni. The electrocatalytic properties of crystalline Ni₃P with elemental Ni inclusions were also investigated by electrochemical characterization.

Keywords: nickel phosphide, pulse-reverse electrodeposition, hydrogen evolution reaction, Ni precipitate, volmer-heypoovsky route

INTRODUCTION

Research on environmentally friendly renewable energy has been conducted to replace fossil fuels with limited reserves. Hydrogen energy (H₂) with high gravimetric density has been researched as a candidate for an environmentally friendly sustainable energy source (Kapdan and Kargi, 2006; Nikolaidis and Poullikkas, 2017). Nowadays, hydrogen was dominantly produced by the steam reforming of natural gases with the emission of carbon dioxide as a by-product (Muradov and Veziroğlu, 2005). Electrochemical water splitting operating in a sustainable manner, such as wind and solar power, has been applied to produce green hydrogen as a promising approach. Water splitting is a chemical reaction in which water is separated into hydrogen and oxygen by applying an electric current. The representative technologies of electrochemical water splitting can be categorized in alkaline water electrolysis (AEL), proton exchange membrane electrolysis (or polymer electrolyte membrane) (PEMEL), and solid oxide electrolysis (SOEL) (Brisse et al., 2008; Carmo et al., 2013; David et al., 2019; Shiva Kumar and Himabindu, 2019; Brauns and Turek, 2020). The water splitting
reaction was typically performed in the corrosive media of an acidic or alkaline electrolyte. The fabrication of stable and efficient electrocatalysts with low overpotentials for both hydrogen evolution reaction (HER) and oxygen evolution reaction (OER) in water splitting is still a challenging issue. Pt for HER and Ir/Ru oxides as commercial electrocatalytic materials have been utilized. However, the high cost of noble materials is a key limiting factor for application to a large-scale system. Non-noble materials such as metal oxides, chalcogenides, sulfides, nitrides, carbides, and phosphides have been investigated to replace precious electrocatalytic materials (Brown et al., 1984; Raj and Vasu, 1996; Liu and Rodriguez, 2005; McKone et al., 2011; Merki and Hu, 2011; Vrubel and Hu, 2012; Jiang et al., 2014; Kucernak and Sundaram, 2014; Pu et al., 2014; Pan et al., 2015a; Pan et al., 2015b; Wang et al., 2015; Chen et al., 2018; Zhao et al., 2020). Among them, nickel phosphide (Ni-P) compounds have been attracting attention as one of the promising candidates for both HER and OER electrocatalysts. The Ni-P compounds typically exist in the crystalline phases of Ni5P4, Ni12P5, Ni3P2, and Ni3P4. The relatively higher positive charges of Ni and the stronger ensemble effect of phosphorous with increasing contents of phosphorous in Ni-P compounds have been reported to improve the catalytic activities especially for HER due to the easier desorption of H2 (Pan et al., 2015b; Menezes et al., 2017). The Ni-P electrocatalysts for water splitting have been fabricated by various approaches, such as colloidal synthesis, phosphorylation, physical vapor deposition, chemical vapor deposition, plasma spraying method, and electrodeposition (Wu and Duh, 2003; Mahalingam et al., 2007; Pannierselvam et al., 2008; Wu and Wu, 2013; Cai et al., 2015; Kornienko et al., 2017; Hasannaemini and Mukherjee, 2019; Kim et al., 2019; Suryawanshi et al., 2020). The electrodeposition technique can be performed to deposit homogeneous Ni-P electrocatalysts in low temperature and atmospheric pressure without high-cost facilities. The contents of phosphorous in Ni-P electrodeposits have been controlled to enhance the electrocatalytic performance by adjusting electrochemical parameters such as the concentration of phosphorus acid, the applied voltage, the applied current, and deposition time (Bonino et al., 1997; Bai et al., 2003; Krolikowski et al., 2006; Mahalingam et al., 2007; Pu et al., 2014; Jiang et al., 2016; Hasannaemini and Mukherjee, 2019). However, the phosphorous contents in Ni-P electrodeposits are difficult to increase with typical potentiostatic or galvanostatic deposition techniques, since the deposition was conducted by the indirect electrodeposition mechanism called induced co-deposition (Mahalingam et al., 2007; Hasannaemini and Mukherjee, 2019). Compared to the potentiostatic/galvanostatic and typical pulse electrodeposition techniques with the limited phosphorous contents in Ni-P compounds, a pulse-reverse electrodeposition technique can be employed as the efficient approach to increase the contents of phosphorous in Ni-P compounds. The relative phosphorous contents in Ni-P electrocatalysts can be increased by the selective dissolution of Ni elements in an anodic reaction for the reverse pulse. Therefore, the composition of Ni-P electrocatalysts can be minutely controlled by tailoring a duty cycle of pulse-reverse electrodeposition. A few studies for Ni-P pulse-reverse electrodeposition have been reported (Wu and Wu, 2013; Wu et al., 2015; Kim et al., 2019).

In this paper, the electrochemical behavior of the Ni-P compound was analyzed by cyclic voltammetry. Ni-P compounds as a HER electrocatalyst for the water splitting were fabricated by utilizing a pulse-reverse electrodeposition technique. Compared to the typical Ni-P prepared by a potentiostatic deposition and a pulse electrodeposition, the composition of the amorphous Ni-P electrocatalysts was systematically controlled by controlling the duty cycle of applied pulses in the pulse-reverse electrodeposition. The electrocatalytic properties and the electrochemical behaviors of Ni-P compounds for HER of water splitting in acidic media were intensely investigated as a function of the tailored contents of phosphorous in Ni-P by polarization curves, Tafel plots, and Nyquist plots. Additionally, the electrodeposited Ni-P electrocatalysts with an amorphous phase were annealed. The electrocatalytic properties of the crystallized Ni-P compound were systematically analyzed.

MATERIALS AND METHODS

The Ni-P films were fabricated by pulse-reversed electrodeposition at 30°C using a typical three-electrode configuration with a platinum (Pt) mesh and a saturated calomel electrode (SCE) as the counter electrode and reference electrode, respectively. Fluorine-doped tin oxide glasses (~7 Ω sq.·, Sigma-Aldrich, St. Louis, MO, USA) with an area of 25 × 25 mm were employed as the working electrode. Fluorine-doped tin oxide (FTO) glass substrates were ultrasonically cleaned with deionized water (18 MΩ·cm) and a mixture of ethanol and acetic acid (v/v ratio 1:1) for 20 min and then dried at 80°C for 30 min under air. The electrolyte for the Ni-P electrodeposition consisted of 0.5 M nickel(II) acetate tetrahydrate (Sigma-Aldrich), 0.29 M phosphorous acid (Daejung Chemical, Siheung, South Korea), 0.65 M phosphoric acid (Junsei Chemical, Tokyo, Japan), and 5 wt.% N-methylformamide (NMF, Sigma-Aldrich) with a pH of 3.4. The pulse-reverse electrodeposition was performed by the periodic application of a voltage of -0.85 V (vs. SCE) for the cathodic Ni-P co-deposition reaction and a reverse voltage of -0.2 V (vs. SCE) for the anodic Ni dissolution reaction. The composition of Ni-P electrodeposits was controlled with the varied duty cycles (duty cycle = \( \frac{\text{Time of anodic pulse}}{\text{Time of anodic pulse} + \text{Time of cathodic pulse}} \times 100 \)). The numbers of periodic cycles for the fixed film thickness of about 500 nm were determined by Faraday’s law. The crystalline Ni-P catalyst was prepared by an annealing process at 500°C in Ar(g) for 1 h with a heating rate of 5°C/min.

Material characterization was carried out with an X-ray diffractometer (XRD, D8 Advance, Bruker, Billerica, MA, USA) with Cu-Kα radiation (λ = 1.5418 nm), field-emission scanning electron microscope (FE-SEM, JSM-6700, JEOL, Tokyo, Japan), transmission electron microscope (TEM, Titan Themis Z, FEI), and energy-dispersive x-ray spectroscopy (EDS) equipped with TEM and SEM. Electrochemical analysis was performed with an electrochemical workstation (PMC-1000, AMETEK, Berwyn, PA, USA). The cyclic voltammetry was
Ni-P is achieved by the reaction of Ni²⁺ ions with PH₃ as an indirect mechanism, as described in Eqs 1–3. The formation of Ni-P is achieved by the reaction of Ni²⁺ ions with PH₃ as an intermediate (Mahalingam et al., 2007; Hasannaeimi and Mukherjee, 2019). Two peaks for oxidation reactions were observed in the anodic scan. The first peak at about -0.08 V (vs. SCE) and the second peak at about 0.65 V (vs. SCE) indicate the oxidation of Ni and the dissolution of Ni-P, respectively (Crousier et al., 1993).

\end{align*}
\]

Based on the cyclic voltammetry study for the electrochemical behavior of Ni-P, Ni-P electrodeposits with the tailored contents of phosphorous were prepared by pulse-reverse electrodeposition with the controlled duty cycles for the cathodic reaction of the Ni-P co-deposition and the anodic reaction of the dissolution of Ni. Figures 2A–D show the morphologies of the Ni-P compounds pulse-reverse electrodeposited at the tailored duty cycles of 50%, 60%, 80%, and 100% (DC), respectively. The thickness of Ni-P electrodeposits was controlled at about 527 ± 12.2 nm, as shown in insets of Figures 2A–D. The surface morphologies of Ni-P electrodeposits display the grained structures. Image analyses of the average grain size were accomplished by a linear intercept method. The average grain size of Ni-P electrodeposits decreased with the decrease in the applied duty cycle, as shown in Figure 2E. The increased ion diffusion on a cathode at the lower duty cycle with the longer anodic reaction time can induce the frequent adsorption of ionic species. Therefore, the decrease in the duty cycle of the pulse-reverse Ni-P electrodeposition can lead to the increase in the nucleation rate and the inhibition of the grain growth (Chandrasekar and Pushpavanam, 2008; Wahyudi et al., 2019). The average grain size of Ni-P electrodeposits decreased from 401 nm for the duty cycle of 100% to 263 nm for the duty cycle of 50%. Additionally, the EDS analysis of Ni-P electrodeposited as a function of the tailored duty cycles is described in the graph of Figure 2F. The phosphorous contents in the Ni-P electrodeposits increased with the decrease in the duty cycle. Ni-P electrodeposits at the duty cycles of 100%, 80%, 60%, and 50% indicated the phosphorous contents of 24.7, 25.6, 27.0, and 30.6 at.% respectively. The phosphorous content of 30.6% in Ni-P pulse-reverse electrodeposited at the duty cycle of 50% showed the relatively high 30.6 at.% compared to the phosphorous contents in the Ni-P compounds prepared with conventional DC electrodeposition methods ranging from 12 to 28 at.% (Bonino et al., 1997; Bai et al., 2003; Krolkowski et al., 2006; Mahalingam et al., 2007; Hasannaeimi and Mukherjee, 2019). The increase in phosphorous contents of Ni-P prepared at the lower duty cycle of the pulse-reverse electrodeposition can be attributed to the increased Ni dissolution reaction due to the longer anodic reaction time. The dissolution of Ni in the electrodeposited Ni-P compounds can increase the relative content of phosphorous. Furthermore, the indirect phosphorous co-deposition with Ni requires the indispensable presence of nascent hydrogen to produce PH₃, as described in Eqs 1–3. The increased contents of phosphorous at the lower duty cycle might be attributed to the increased H⁺ ions adsorbed on a cathode required for the PH₃ formation, because the longer anodic reaction time can effectively remove the reduced...
species such as H\textsubscript{2} from the cathode surface (Hasannaeimi and Mukherjee, 2019).

Figure 3 shows the XRD spectra of the pulse-reverse electrodeposited Ni-P at the tailored duty cycles. The well-developed peaks in the diffraction patterns indicate the crystal planes of SnO\textsubscript{2} in FTO substrates. The diffraction peaks were defined as the (110), (101), (200), (211), (310), and (301) planes of SnO\textsubscript{2} (JCPDS, no. 46-1088). The diffraction patterns of the Ni-P electrodeposits were observed as a broad peak at about 44° for the (111) plane of Ni (JCPDS, no. 87-0712). The induced co-deposited phosphorous atoms with Ni for the Ni-P electrodeposition were incorporated into the Ni lattices. Compared to the XRD patterns of the polycrystalline Ni electrodeposits with well-developed peaks, the Ni-P electrodeposits showed the amorphous phase indicating the broad peaks at about 44°. As the contents of phosphorous in Ni-P electrodeposits increase, the crystallinity of Ni-P becomes poor. Additionally, the application of a pulse to enable interference in the continuous crystal growth can aggravate the short-range ordered crystallinity. Therefore, the Ni-P electrodeposits with the induced co-deposition mechanism typically exhibited the poor crystallinity or amorphous phase. Furthermore, the increase in phosphorous contents in Ni-P with decrease in duty cycles intuitively showed the gradual diminution of the intensity for the broad amorphous peak.

The electrocatalytic properties of amorphous Ni-P electrodeposits with tailored compositions were characterized as shown in Figure 4. Polarization curves were measured to characterize the overpotential for HER of amorphous Ni-P compounds in the acidic electrolyte of 0.5 M H\textsubscript{2}SO\textsubscript{4} (Figure 4A). The electrocatalytic activity of a bare FTO substrate without Ni-P electrodeposits for HER was not
observed. The overpotential of the commercial Pt/C for HER has been reported to be approximately -14 mV at -10 mA/cm² (Kim et al., 2019). The overpotentials of Ni₆₉P₃₁, Ni₇₃P₂₇, Ni₇₄P₂₆, and Ni₇₅P₂₅ with the controlled compositions indicated -317, -375, -385, and -396 mV at -10 mA/cm², respectively. The overpotential of amorphous Ni-P electrodeposits for HER was gradually reduced with the increase in the phosphorous contents. The enhanced electrocatalytic properties for HER might be attributed to the lower desorption energy of H₂ due to the reduced negative charge on the surface of phosphorous to trap protons with increasing contents of phosphorous in Ni-P electrodeposits, as well as to the decreased active sites of Ni to reduce the H₂ desorption energy (ensemble effect) (Pan et al., 2015b; Menezes et al., 2017). The kinetics of Ni-P electrodeposits for HER as a function of composition was investigated by Tafel analysis, as shown in Figure 4B. The Tafel slopes of Ni₆₉P₃₁, Ni₇₃P₂₇, Ni₇₄P₂₆, and Ni₇₅P₂₅ decreased with the increase in the contents of phosphorous, indicating 97, 107, 125, and 120 mV/dec, respectively. The mechanism for HER in acidic solutions can be described with three processes of the formation step of Hₐds via the adsorption of H⁺ (Volmer reaction), the desorption step (Heyrovsky reaction), and the combination step (Tafel reaction), as described in Eqs 4–6 (Zeng and Li, 2015). The HER in acidic solutions can be determined by two successive steps of the Volmer–Tafel route or/and the Volmer–Heyrovsky route. The Tafel slopes of Volmer reaction, Heyrovsky reaction, and Tafel reaction as the rate-determining step are 118, 39, and 29.5 mV/dec (Zeng and Li, 2015). The Tafel slope of the Pt electrocatalyst for HER has been reported to be about 30 mV/dec indicating a Volmer–Tafel route with the Tafel reaction as a rate-determining step following the fast initial Volmer reaction. The HER process of Ni-P electrocatalysts has been typically described as Volmer–Heyrovsky route with the Tafel slopes of about 40–75 mV/dec (Pu et al., 2014; Pan et al., 2015b; Zhao et al., 2020). The Tafel slopes of the amorphous Ni-P electrodeposits indicated that the rate-determining step is the Volmer reaction in the mixed kinetic mechanism. The reduction in Tafel slopes with the increase in the contents of phosphorous implied the faster adsorption of intermediate hydrogen atoms on the surface of Ni-P catalysts. Electrochemical impedance spectrometry as a further
kinetic study for HER was analyzed as a function of the composition of Ni-P electrodeposits. The charge transfer resistance of the interface between the Ni-P catalyst and electrolyte was drastically reduced in Ni$_{69}$P$_{31}$ with the highest contents of phosphorous. The enhanced charge transfer of the Ni$_{69}$P$_{31}$ electrocatalyst was in agreement with the results of the analyses of overpotentials and Tafel plots (Figure 4C).

\[ \text{H}^+ + e^- \rightarrow \text{H}_{\text{ads}} \quad \text{(Volmer reaction)} \tag{4} \]
\[ \text{H}_{\text{ads}} + \text{H}^+ + e^- \rightarrow \text{H}_2(g) \quad \text{(Heyrovsky reaction)} \tag{5} \]
\[ \text{H}_{\text{ads}} + \text{H}_{\text{ads}} \rightarrow \text{H}_2(g) \quad \text{(Tafel reaction)} \tag{6} \]

The Ni-P electrodeposits had amorphous phases as shown in Figure 3. Lowering of the duty cycles in the pulse-reverse electrodeposition induced Ni-P electrodeposits to become further amorphous, aggravating the short-range ordered crystallinity due to the brief periodic deposition time and increase in phosphorous contents. The amorphous Ni$_{69}$P$_{31}$ electrodeposited at the duty cycle of 50% was annealed at 500°C in Ar 7(g) for 1 h. Figure 5 shows the XRD patterns of the annealed Ni$_{69}$P$_{31}$ electrodeposit. Compared to the XRD pattern of the bare Ni$_{69}$P$_{31}$ electrodeposit, the diffraction patterns of annealed Ni$_{69}$P$_{31}$ shows the well-developed peaks, indicating the crystallization of amorphous Ni$_{69}$P$_{31}$. The diffraction peaks were defined as the (301), (321), (330), (112), (420), (141), and (321) planes of Ni$_3$P (JCPDS, no. 74-1384) and the (111) and (220) planes of Ni (JCPDS, no. 87-0712). As described in XRD analysis, the amorphous Ni$_{69}$P$_{31}$ electrodeposit was transformed into two crystal structures of Ni$_3$P and Ni by the annealing process.

![Figure 5](image)

**Figure 5** | XRD patterns of the annealed Ni$_{69}$P$_{31}$ electrodeposit.

![Figure 6](image)

**Figure 6** | Structural characterization of the crystalline Ni$_3$P with elemental Ni inclusions prepared by annealing of amorphous Ni$_{69}$P$_{31}$ electrodeposit: (A) FE-SEM image (SEM scale bar and thickness display), (B) bright-field TEM image, (C) HRTEM image, (D) STEM image, and (E, F) EDS elemental mapping for Ni and phosphorous.
SEM and TEM analyses of the annealed Ni$_{69}$P$_{31}$ electrodeposit was conducted as shown in Figure 6. The surface morphology of the crystallized Ni$_{69}$P$_{31}$ electrodeposit was similar to the surface of the as-deposited amorphous Ni$_{69}$P$_{31}$ with the grain boundaries, as shown in Figure 6A. Corresponding with the XRD analysis, TEM images of the annealed Ni$_{69}$P$_{31}$ electrodeposit clearly showed the interface between the Ni precipitates and Ni$_3$P with well-developed lattice structures. The HRTEM image revealed a crystalline structure for Ni precipitates with a lattice spacing of 0.205 nm and for Ni$_3$P with a lattice spacing of 0.199 nm, corresponding to the (111) planes of Ni (JCPDS, no. 87-0712) and the (420) planes of Ni$_3$P (JCPDS, no. 74-1384). The elemental precipitation of Ni in the matrix of Ni$_3$P can be obviously confirmed from STEM and EDS elemental mapping analysis, indicating the compositional distribution of Ni$_3$P/Ni. The excess elemental Ni over Ni$_3$P with the stoichiometric composition in Ni$_{69}$P$_{31}$ might be precipitated for the annealing process.

The electrocatalytic properties of crystalline Ni$_3$P with elemental Ni inclusions was characterized as shown in Figure 7. The crystalline Ni$_3$P with elemental Ni inclusions indicated the lower overpotential of -275 mV at -10 mA/cm$^2$ for HER, compared to the HER overpotential of -317 mV in the amorphous Ni$_{69}$P$_{31}$ and the overpotential of -468 mV in the crystalline Ni film. The Tafel slope of the crystalline Ni$_3$P with elemental Ni inclusions indicated 86 mV/dec which is smaller than the Tafel slope of 97 mV/dec and 133 mV/dec in the amorphous Ni$_{69}$P$_{31}$ and crystalline Ni film, respectively. Based on the Tafel slope of 86 mV/dec in the crystalline Ni$_3$P with elemental Ni inclusions, the rate-determining step is still predicted to be the Volmer reaction in the Volmer–Heyrovsky route. However, the adsorption energy of intermediate hydrogen atoms on the surface of crystalline Ni$_3$P with elemental Ni inclusions can be anticipated to be reduced, compared to the adsorption energy in the amorphous Ni$_{69}$P$_{31}$. The analysis of electrochemical impedance spectrometry showed the reduced charge transfer resistance of the interface between elemental Ni-embedded crystalline Ni$_3$P and electrolyte. The electrocatalytic performance of Ni-P compounds for HER can be improved by the balanced control of the Volmer reaction for the adsorption of protons and the Heyrovsky reaction for the desorption of H$_2$, considering the exposure of active sites with low energy barrier. The improved overpotential, Tafel slope, and charge transfer in the crystalline Ni$_3$P with elemental Ni inclusions might be attributed to the lower desorption energy of hydrogen for Heyrovsky reaction and the lower adsorption energy for Volmer reaction. The energy for the H$_2$ desorption (Heyrovsky reaction) in the crystalline Ni$_3$P with Ni inclusions prepared from amorphous Ni$_{69}$P$_{31}$ with the highest phosphorous content was decreased by the enhanced ensemble effect. Moreover, the strong hydride formation in the Ni hollow sites of the crystallized Ni$_3$P with Ni inclusions reduced the adsorption resistance.
energy for proton adsorption reaction (Volmer reaction) called
the ligand effect (Liu and Rodriguez, 2005; Chen et al., 2017).
Additionally, the ECSA of the crystalline Ni₃P with elemental Ni
inclusions was characterized with the double-layer capacitance of
the catalytic surface (McCrory et al., 2013). The double-layer
capacitance (Cdl) indicated 331.48 μF/cm², which was calculated
with the non-Faradaic double-layer charging current from the
cyclic voltammograms at the varied scan rates. The calculated
ECSA of the crystalline Ni₃P with elemental Ni inclusions was
8.29 cm² corresponding to the ECSA of typical electrodeposited
Ni film with about 8.13 cm² (Zhou et al., 2017).

The ADT was performed to evaluate the stability of the
crystalline Ni₃P with elemental Ni inclusions for the HER
electrocatalyst, as shown in Figure 8. The ADT polarization
curves showed the degradation of the electrocatalytic
properties with the increase in the number of cycles. The cycle-dependent overpotentials in the current density of
10 mA/cm² indicated -262 mV at 1 cycle, -241 mV at 1,600
cycles, -287 mV at 2,000 cycles, and -455 mV at 2,500 cycles,
respectively. The polarization curve of 1,600 cycles slightly
deviated with the overpotential of -241 mV, compared to the
initial curve of 1 cycle with the overpotential of -262 mV. The
severe deviation of the polarization curve with the overpotential
of -455 mV after 2,500 cycles indicated the significant loss of the
electrocatalytic properties.

CONCLUSION

The electrochemical behaviors for the Ni-P electrodeposition
were characterized by cyclic voltammetry, indicating the Ni-P
co-deposition in cathodic sweep, the oxidation of Ni, and the
dissolution of Ni-P in anodic sweep. The pulse-reverse
electrodeposition including the Ni-P co-deposition and the
dissolution of Ni was utilized to deposit Ni-P films with
tailored compositions. Ni₆₉P₃₁, Ni₇₃P₂₇, Ni₇₄P₂₆, and Ni₇₅P₂₅
electrodeposits with the amorphous phase were prepared by
adjusting the duty cycles of pulse-reverse electrodeposition. The
overpotentials at -10 mA/cm² and Tafel slopes of the amorphous Ni-P electrodeposits for HER were reduced from
-396 and 120 mV/dec to -317 and 97 mV/dec, as the contents of
phosphorous in Ni-P increased from Ni₇₅P₂₅ to Ni₆₉P₃₁. The
analysis of electrochemical impedance spectrometry also showed
the reduction of charge transfer resistance of the interface
between Ni-P and electrolyte with increase in the contents of
phosphorous. The improvement of electrocatalytic properties in
amorphous Ni-P electrodeposits with increase in the contents of
phosphorous can be achieved by the reduction of the H₂
desorption energy. Additionally, crystalline elemental Ni-
embedded Ni₃P were prepared by the annealing of the
amorphous Ni₆₉P₃₁ electrodeposited. The electrocatalytic
properties of the crystalline Ni₃P with elemental Ni inclusions
for HER indicated the lower overpotential of -275 mV at -10 mA/
cm², the gentler Tafel slope of 86 mV/dec, and the reduced charge
transfer resistance, compared to the properties of the amorphous
Ni₆₉P₃₁. Compared to the HER catalytic properties in the
amorphous Ni₆₉P₃₁, the enhanced electrocatalytic properties in
the crystalline Ni₃P with Ni inclusions might be attributed to the
lower desorption energy of hydrogen for Heyrovsky reaction and
the lower adsorption energy for Volmer reaction. The improved
hydrogen desorption and proton adsorption processes for HER
catalytic properties can be described by an ensemble effect and a
ligand effect, respectively. The crystalline Ni₃P with elemental Ni
inclusions demonstrated the continuous stability for HER
catalytic properties up to 1,600 cycles in acidic solution.
