MOT20: A benchmark for multi object tracking in crowded scenes

Patrick Dendorfer, Hamid Rezatofighi, Anton Milan, Javen Shi, Daniel Cremers, Ian Reid, Stefan Roth, Konrad Schindler, and Laura Leal-Taixé

Abstract—Standardized benchmarks are crucial for the majority of computer vision applications. Although leaderboards and ranking tables should not be over-claimed, benchmarks often provide the most objective measure of performance and are therefore important guides for research. The benchmark for Multiple Object Tracking, MOTChallenge, was launched with the goal to establish a standardized evaluation of multiple object tracking methods. The challenge focuses on multiple people tracking, since pedestrians are well studied in the tracking community, and precise tracking and detection has high practical relevance. Since the first release, MOT15 [5], MOT16 [8], and MOT17 [8] have tremendously contributed to the community by introducing a clean dataset and precise framework to benchmark multi-object trackers. In this paper, we present our MOT20 benchmark, consisting of 8 new sequences depicting very crowded challenging scenes. The benchmark was presented first at the 4th BMTT MOT Challenge Workshop at the Computer Vision and Pattern Recognition Conference (CVPR) 2019, and gives to chance to evaluate state-of-the-art methods for multiple object tracking when handling extremely crowded scenarios.

Index Terms—multiple people tracking, benchmark, evaluation metrics, dataset

1 INTRODUCTION

Since its first release in 2014, MOTChallenge has attracted more than 1,000 active users who have successfully submitted their trackers and detectors to five different challenges, spanning 44 sequences with 2.7M bounding boxes over a total length of 36k seconds. As evaluating and comparing multi-target tracking methods is not trivial (cf. e.g. [10]), MOTChallenge provides carefully annotated datasets and clear metrics to evaluate the performance of tracking algorithms and pedestrian detectors. Parallel to the MOTChallenge all-year challenges, we organize workshop challenges on multi-object tracking for which we often introduce new data.

In this paper, we introduce the MOT20 benchmark, consisting of 8 novel sequences out of 3 very crowded scenes. All sequences have been carefully selected and annotated according to the evaluation protocol of previous challenges [5], [8]. This benchmark addresses the challenge of very crowded scenes in which the density can reach values of 246 pedestrians per frame. The sequences were filmed in both indoor and outdoor locations, and include day and night time shots. Figure 1 shows the split of the sequences of the three scenes into training and testing sets. The testing data consists of sequences from known as well as from an unknown scenes in order to measure the generalization capabilities of both detectors and trackers. We make available the images for all sequences, the ground truth annotations for the training protocol introduced in MOT16, ensuring that every moving person or vehicle within each sequence is annotated with a bounding box as accurately as possible. In the following, we define a clear protocol that was obeyed throughout the entire dataset to guarantee consistency.

sequences were filmed in both indoor and outdoor locations, and include day and night time shots. Figure 1 shows the split of the sequences of the three scenes into training and testing sets. The testing data consists of sequences from known as well as from an unknown scenes in order to measure the generalization capabilities of both detectors and trackers. We make available the images for all sequences, the ground truth annotations for the training set as well as a set of public detections (obtained from a Faster R-CNN trained on the training data) for the tracking challenge.

The MOT20 challenges and all data, current ranking and submission guidelines can be found at:

\[\text{http://www.motchallenge.net/}\]

2 ANNOTATION RULES

For the annotation of the dataset, we follow the protocol introduced in MOT16, ensuring that every moving person or vehicle within each sequence is annotated with a bounding box as accurately as possible. In the following, we define a clear protocol that was obeyed throughout the entire dataset to guarantee consistency.

2.1 Target class

In this benchmark, we are interested in tracking moving objects in videos. In particular, we are interested in evaluating multiple people tracking algorithms, hence, people will be the center of attention of our annotations. We divide the pertinent classes into three categories:
(i) moving pedestrians;
(ii) people that are not in an upright position, not moving, or artificial representations of humans; and
(iii) vehicles and occluders.

In the first group, we annotate all moving pedestrians that appear in the field of view and can be determined as such by the viewer. Furthermore, if a person briefly bends over or squats, e.g., to pick something up or to talk to a child, they shall remain in the standard pedestrian class. The algorithms that submit to our benchmark are expected to track these targets.

In the second group, we include all people-like objects whose exact classification is ambiguous and can vary depending on the viewer, the application at hand, or other factors. We annotate all static people, e.g., sitting, lying down, or do stand still at the same place over the whole sequence. The idea is to use these annotations in the evaluation such that an algorithm is neither penalized nor rewarded for tracking, e.g., a sitting or not moving person.

In the third group, we annotate all moving vehicles such as cars, bicycles, motorbikes and non-motorized vehicles (e.g., strollers), as well as other potential occluders. These annotations will not play any role in the evaluation, but are provided to the users both for training purposes and for computing the level of occlusion of pedestrians. Static vehicles (parked cars, bicycles) are not annotated as long as they do not occlude any pedestrians.

3 Datasets

The dataset for the new benchmark has been carefully selected to challenge trackers and detectors on extremely crowded scenes. In contrast to previous challenges, some of the new sequences show a pedestrian density of 246 pedestrians per frame. In Fig. 1 and Tab. 1 we show an overview of the sequences included in the benchmark.

3.1 MOT 20 sequences

We have compiled a total of 8 sequences, of which we use half for training and half for testing. The annotations of the testing sequences will not be released in order to avoid (over)fitting of the methods to the specific sequences. The sequences are filmed in three different scenes. Several sequences are filmed per scene and distributed in the train and test sets. One of the scenes though, is reserved for test time, in order to challenge the generalization capabilities of the methods.

The new data contains circa 3 times more bounding boxes for training and testing compared to MOT17. All sequences are filmed in high resolution from an elevated viewpoint, and the mean crowd density reaches 246 pedestrians per frame which 10 times denser when compared to the first benchmark release. Hence, we expect the new sequences to be more challenging for the tracking community and to push the models to their limits when it comes to handling extremely crowded scenes. In Tab. 1 we give an overview of the training and testing sequence characteristics for the challenge, including the number of bounding boxes annotated.

Aside from pedestrians, the annotations also include other classes like vehicles or bicycles, as detailed in Sec. 2 In Tab. 2 we detail the types of annotations that can be found in each sequence of MOT20.
### Table 1: Overview of the sequences currently included in the MOT20 benchmark considering pedestrians.

| Sequence | FPS | Resolution | Length | Tracks | Boxes | Density | Description | Source |
|----------|-----|------------|--------|--------|-------|---------|-------------|--------|
| MOT20-01 | 25  | 1920x1080  | 429 (00:17) | 74 | 19,870 | 46.32 | indoor | new |
| MOT20-02 | 25  | 1920x1080  | 2,782 (01:51) | 270 | 154,742 | 55.62 | indoor | new |
| MOT20-03 | 25  | 1173x880   | 2,405 (01:36) | 702 | 313,658 | 130.42 | outdoor, night | new |
| MOT20-05 | 25  | 1654x1080  | 3,315 (02:13) | 1169 | 646,344 | 194.98 | outdoor, night | new |
| **Total training** | 8,931 (05:57) | 2,215 | 1,134,614 | 127.04 |

### Table 2: Overview of the types of annotations currently found in the MOT20 benchmark.

| Sequence | Pedestrian | Non motorized vehicle | Static person | Occluder on the ground | Crowd | Total |
|----------|------------|-----------------------|---------------|------------------------|-------|-------|
| MOT20-01 | 19,870     | 0                     | 2,574         | 4,203                  | 0     | 26,647 |
| MOT20-02 | 154,742    | 4,021                 | 11,128        | 32,324                 | 0     | 202,215 |
| MOT20-03 | 313,658    | 1,436                 | 22,310        | 16,835                 | 0     | 356,728 |
| MOT20-04 | 274,084    | 3,110                 | 92,251        | 2,080                  | 0     | 371,525 |
| MOT20-05 | 646,344    | 7,513                 | 90,843        | 6,630                  | 0     | 751,330 |
| MOT20-06 | 132,757    | 1,248                 | 60,102        | 12,428                 | 0     | 207,543 |
| MOT20-07 | 33,101     | 800                   | 3,685         | 9,776                  | 0     | 41,301  |
| MOT20-08 | 77,484     | 4,237                 | 52,998        | 9,576                  | 0     | 145,301 |
| **Total** | 1,652,040  | 22,365                | 335,891       | 87,786                 | 4,303 | 2,102,385 |

### 3.2 Detections

We trained a Faster R-CNN [11] with ResNet101 [4] backbone on the MOT20 training sequences, obtaining the detection results presented in Table 3. This evaluation follows the standard protocol for the MOT20 challenge and only accounts for pedestrians. Static persons and other classes are not considered and filtered out from both, the detections, as well as the ground truth.

A detailed breakdown of detection bounding boxes on individual sequences is provided in Tab. 3.

| Seq     | nDet. | nDet./fr. | min height | max height |
|---------|-------|-----------|------------|------------|
| MOT20-01 | 12610 | 29.39     | 30.00 289  |
| MOT20-02 | 89837 | 32.29     | 25.00 463  |
| MOT20-03 | 177347| 73.74     | 16.00 161  |
| MOT20-04 | 228298| 109.76    | 23.00 241  |
| MOT20-05 | 381349| 115.04    | 26.00 245  |
| MOT20-06 | 69467 | 68.92     | 27.00 304  |
| MOT20-07 | 20330 | 34.75     | 21.00 381  |
| MOT20-08 | 43703 | 54.22     | 37.00 302  |
| **Total** | 1022941| 76.28     | 16.00 463  |

### 3.3 Data format

All images were converted to JPEG and named sequentially to a 6-digit file name (e.g., 000001.jpg). Detection and annotation files are simple comma-separated value (CSV) files. Each line represents one object instance and contains 9 values as shown in Tab. 4.

The first number indicates in which frame the object appears, while the second number identifies that object as belonging to a trajectory by assigning a unique ID (set to −1 in a detection file, as no ID is assigned yet). Each object can be assigned to only one trajectory. The next four numbers indicate the position of the bounding box of the pedestrian in 2D image coordinates. The position is indicated by the top-left corner as well as width and height of the bounding box. This is followed by a single number, which in case of detections denotes their confidence score. The last two numbers for detection files are ignored (set to -1).

An example of such a 2D detection file is:

```
1, -1, 794.2, 47.5, 71.2, 174.8, 67.5, -1, -1
1, -1, 164.1, 19.6, 66.5, 163.2, 29.4, -1, -1
1, -1, 875.4, 39.9, 25.3, 145.0, 19.6, -1, -1
2, -1, 781.7, 25.1, 69.2, 170.2, 58.1, -1, -1
```

For the ground truth and results files, the 7th value (confidence score) acts as a flag whether the entry is to be considered. A value of 0 means that this particular instance is ignored in the evaluation, while a value of 1 is used to mark it as active. The 8th number indicates the type of object annotated, following the convention of Tab. 5. The last number shows the visibility ratio of each object.

For the tracking challenge, we provide these public detections as a baseline to be used for training and testing of the trackers. For the MOT20 challenge, we will only accept results on public detections. When later the benchmark will be open for continuous submissions, we will accept both public as well as private detections.
Position | Name | Description
--- | --- | ---
1 | Frame number | Indicate at which frame the object is present
2 | Identity number | Each pedestrian trajectory is identified by a unique ID (−1 for detections)
3 | Bounding box left | Coordinate of the top-left corner of the pedestrian bounding box
4 | Bounding box top | Coordinate of the top-left corner of the pedestrian bounding box
5 | Bounding box width | Width in pixels of the pedestrian bounding box
6 | Bounding box height | Height in pixels of the pedestrian bounding box
7 | Confidence score | DET: Indicates how confident the detector is that this instance is a pedestrian.
| | | GT: It acts as a flag whether the entry is to be considered (1) or ignored (0).
8 | Class | GT: Indicates the type of object annotated
9 | Visibility | GT: Visibility ratio, a number between 0 and 1 that says how much of that object is visible. Can be due to occlusion and due to image border cropping.

TABLE 4: Data format for the input and output files, both for detection (DET) and annotation/ground truth (GT) files.

| Label | ID |
| --- | --- |
| Pedestrian | 1 |
| Person on vehicle | 2 |
| Car | 3 |
| Bicycle | 4 |
| Motorbike | 5 |
| Non motorized vehicle | 6 |
| Static person | 7 |
| Distractor | 8 |
| Occluder | 9 |
| Occluder on the ground | 10 |
| Occluder full | 11 |
| Reflection | 12 |
| Crowd | 13 |

TABLE 5: Label classes present in the annotation files and ID appearing in the 8th column of the files as described in Tab. 4.

4 EVALUATION

Our framework is a platform for fair comparison of state-of-the-art tracking methods. By providing authors with standardized ground truth data, evaluation metrics and scripts, as well as a set of precomputed detections, all methods are compared under the exact same conditions, thereby isolating the performance of the tracker from everything else. In the following paragraphs, we detail the set of evaluation metrics that we provide in our benchmark.

4.1 Evaluation metrics

In the past, a large number of metrics for quantitative evaluation of multiple target tracking have been proposed [2], [6], [12]–[14], [16]. Choosing “the right” one is largely application dependent and the quest for a unique, general evaluation metric is still ongoing. On the one hand, it is desirable to summarize the performance into one single number to enable a direct comparison. On the other hand, one might not want to lose information about the individual errors made by the algorithms and provide several performance estimates, which precludes a clear ranking.

Following a recent trend [1], [9], [15], we employ two sets of measures that have established themselves in the literature: The CLEAR metrics proposed by Stiefelhagen et al. [14], and a set of track quality measures introduced by Wu and Nevatia [16]. The evaluation scripts used in our benchmark are publicly available.[1]

4.1.1 Tracker-to-target assignment

There are two common prerequisites for quantifying the performance of a tracker. One is to determine for each hypothesized output, whether it is a true positive (TP) that describes an actual (annotated) target, or whether the output is a false alarm (or false positive, FP). This decision is typically made by thresholding based on a defined distance (or dissimilarity) measure $d$ (see Sec. 4.1.2). A target that is missed by any hypothesis is a false negative (FN). A good result is expected to have as few FPs and FNs as possible. Next to the absolute numbers, we also show the false positive ratio measured by the number of false alarms per frame (FAF), sometimes also referred to as false positives per image (FPPI) in the object detection literature.

Obviously, it may happen that the same target is covered by multiple outputs. The second prerequisite before computing the numbers is then to establish the

Fig. 3: Four cases illustrating tracker-to-target assignments. (a) An ID switch occurs when the mapping switches from the previously assigned red track to the blue one. (b) A track fragmentation is counted in frame 3 because the target is tracked in frames 1-2, then interrupts, and then reacquires its ‘tracked’ status at a later point. A new (blue) track hypothesis also causes an ID switch at this point. (c) Although the tracking results is reasonably good, an optimal single-frame assignment in frame 1 is propagated through the sequence, causing 5 missed targets (FN) and 4 false positives (FP). Note that no fragmentations are counted in frames 3 and 6 because tracking of those targets is not resumed at a later point. (d) A degenerate case illustrating that target re-identification is not handled correctly. An interrupted ground truth trajectory will cause a fragmentation. Note the less intuitive ID switch, which is counted because blue is the closest target in frame 5 that is not in conflict with the mapping in frame 4.

For the following, we assume that each ground truth trajectory has one unique start and one unique end point, i.e. that it is not fragmented. Note that the current evaluation procedure does not explicitly handle target re-identification. In other words, when a target leaves the field-of-view and then reappears, it is treated as an unseen target with a new ID. As proposed in [14], the optimal matching is found using Munkre’s (a.k.a. Hungarian) algorithm. However, dealing with video data, this matching is not performed independently for each frame, but rather considering a temporal correspondence. More precisely, if a ground truth object $i$ is matched to hypothesis $j$ at time $t - 1$ and the distance (or dissimilarity) between $i$ and $j$ in frame $t$ is below $t_d$, then the correspondence between $i$ and $j$ is carried over to frame $t$ even if there exists another hypothesis that is closer to the actual target. A mismatch error (or equivalently an identity switch, IDSW) is counted if a ground truth target $i$ is matched to track $j$ and the last known assignment was $k \neq j$. Note that this definition of ID switches is more similar to [6] and stricter than the original one [14]. Also note that, while it is certainly desirable to keep the number of ID switches low, their absolute number alone is not always expressive to assess the overall performance, but should rather be considered in relation to the number of recovered targets. The intuition is that a method that finds twice as many trajectories will almost certainly produce more identity switches. For that reason, we also state the relative number of ID switches, i.e., IDSW/Recall.

These relationships are illustrated in Fig. 3. For simplicity, we plot ground truth trajectories with dashed curves, and the tracker output with solid ones, where the color represents a unique target ID. The grey areas indicate the matching threshold (see next section). Each true target that has been successfully recovered in one particular frame is represented with a filled black dot with a stroke color corresponding to its matched hypothesis. False positives and false negatives are plotted as empty circles. See figure caption for more details.

After determining true matches and establishing correspondences it is now possible to compute the metrics. We do so by concatenating all test sequences and evaluating on the entire benchmark. This is in general more meaningful instead of averaging per-sequences figures due to the large variation in the number of targets.
4.1.2 Distance measure
In the most general case, the relationship between ground truth objects and a tracker output is established using bounding boxes on the image plane. Similar to object detection \[3\], the intersection over union (a.k.a. the Jaccard index) is usually employed as the similarity criterion, while the threshold \(t_d\) is set to 0.5 or 50%.

4.1.3 Target-like annotations
People are a common object class present in many scenes, but should we track all people in our benchmark? For example, should we track static people sitting on a bench? Or people on bicycles? How about people behind a glass? We define the target class of CVPR19 as all upright walking people that are reachable along the viewing ray without a physical obstacle, \(i.e.\) reflections, people behind a transparent wall or window are excluded. We also exclude from our target class people on bicycles or other vehicles. For all these cases where the class is very similar to our target class (see Figure 4), we adopt a similar strategy as in \[7\]. That is, a method is neither penalized nor rewarded for tracking or not tracking those similar classes. Since a detector is likely to fire in those cases, we do not want to penalize a tracker with a set of false positives for properly following that set of detections, \(i.e.\) of a person on a bicycle. Likewise, we do not want to penalize with false negatives a tracker that is based on motion cues and therefore does not track a sitting person.

In order to handle these special cases, we adapt the tracker-to-target assignment algorithm to perform the following steps:

1) At each frame, all bounding boxes of the result file are matched to the ground truth via the Hungarian algorithm.

2) In contrast to MOT17 we account for the very crowded scenes and exclude result boxes that overlap > 75% with one of these classes (distractor, static person, reflection, person on vehicle) and remove them from the solution in the detection challenge.

3) During the final evaluation, only those boxes that are annotated as pedestrians are used.

4.1.4 Multiple Object Tracking Accuracy
The MOTA \[14\] is perhaps the most widely used metric to evaluate a tracker’s performance. The main reason for this is its expressiveness as it combines three sources of errors defined above:

\[
MOTA = 1 - \frac{\sum_t (FN_t + FP_t + IDSW_t)}{\sum_t GT_t},
\]

where \(t\) is the frame index and \(GT\) is the number of ground truth objects. We report the percentage MOTA \((-\infty, 100]\) in our benchmark. Note that MOTA can also be negative in cases where the number of errors made by the tracker exceeds the number of all objects in the scene.

Even though the MOTA score gives a good indication of the overall performance, it is highly debatable whether this number alone can serve as a single performance measure.

Robustness. One incentive behind compiling this benchmark was to reduce dataset bias by keeping the data as diverse as possible. The main motivation is to challenge state-of-the-art approaches and analyze their performance in unconstrained environments and on unseen data. Our experience shows that most methods can be heavily overfitted on one particular dataset, and may not be general enough to handle an entirely different setting without a major change in parameters or even in the model.

To indicate the robustness of each tracker across all benchmark sequences, we show the standard deviation of their MOTA score.

4.1.5 Multiple Object Tracking Precision
The Multiple Object Tracking Precision is the average dissimilarity between all true positives and their corresponding ground truth targets. For bounding box overlap, this is computed as

\[
MOTP = \frac{\sum_{t,i} d_{t,i}}{\sum_t c_t},
\]

where \(c_t\) denotes the number of matches in frame \(t\) and \(d_{t,i}\) is the bounding box overlap of target \(i\) with its assigned ground truth object. MOTP thereby gives the average overlap between all correctly matched hypotheses and their respective objects and ranges between \(t_d := 50\% \) and 100%.

It is important to point out that MOTP is a measure of localization precision, not to be confused with the positive predictive value or relevance in the context of precision / recall curves used, \(e.g.\) in object detection.

In practice, it mostly quantifies the localization accuracy of the detector, and therefore, it provides little information about the actual performance of the tracker.

4.1.6 Track quality measures
Each ground truth trajectory can be classified as mostly tracked (MT), partially tracked (PT), and mostly lost (ML). This is done based on how much of the trajectory is recovered by the tracking algorithm. A target is mostly tracked if it is successfully tracked for at least 80% of its life span. Note that it is irrelevant for this measure whether the ID remains the same throughout the track. If a track is only recovered for less than 20% of its total length, it is said to be mostly lost (ML). All other tracks are partially tracked. A higher number of MT and few ML is desirable. We report MT and ML as a ratio of mostly tracked and mostly lost targets to the total number of ground truth trajectories.

In certain situations one might be interested in obtaining long, persistent tracks without gaps of untracked periods. To that end, the number of track fragmentations
Fig. 4: The annotations include different classes. The target class are pedestrians (left). Besides pedestrians there exist special classes in the data such as static person and non-motorized vehicles (non mot vhcl). However, these classes are filter out during evaluation and do not effect the test score. Thirdly, we annotate occluders and crowds. (FM) counts how many times a ground truth trajectory is interrupted (untracked). In other words, a fragmentation is counted each time a trajectory changes its status from tracked to untracked and tracking of that same trajectory is resumed at a later point. Similarly to the ID switch ratio (cf. Sec. 4.1.1), we also provide the relative number of fragmentations as FM / Recall.

4.1.7 Tracker ranking

As we have seen in this section, there are a number of reasonable performance measures to assess the quality of a tracking system, which makes it rather difficult to reduce the evaluation to one single number. To nevertheless give an intuition on how each tracker performs compared to its competitors, we compute and show the average rank for each one by ranking all trackers according to each metric and then averaging across all performance measures.

5 Conclusion and Future Work

We have presented a new challenging set of sequences within the MOTChallenge benchmark. Theses sequences contain a large number of targets to be tracked and the scenes are substantially more crowded when compared to previous MOTChallenge releases. The scenes are carefully chosen and included indoor/ outdoor and day/night scenarios.

We believe that the MOT20 release within the already established MOTChallenge benchmark provides a fairer comparison of state-of-the-art tracking methods, and challenges researchers to develop more generic methods that perform well in unconstrained environments and on very crowded scenes.
