THE DEGENERATE J-FLOW AND THE MABUCHI ENERGY
ON MINIMAL SURFACES OF GENERAL TYPE

JIAN SONG AND BEN WEINKOVE

Abstract. We prove existence, uniqueness and convergence of solutions of
the degenerate J-flow on Kähler surfaces. As an application, we establish the
properness of the Mabuchi energy for Kähler classes in a certain subcone of
the Kähler cone on minimal surfaces of general type.

1. Introduction

Let $M$ be a compact Kähler surface with two Kähler metrics $\omega_0$ and $\chi_0$. Let
$\mathcal{P}_{\chi_0}$ be the space of smooth functions $\varphi$ with $\chi_\varphi := \chi_0 + d\varphi > 0$. The J-flow is
a parabolic flow defined on $\mathcal{P}_{\chi_0}$ by

$$\frac{\partial}{\partial t} \varphi = c_0 - \frac{2\chi_\varphi \wedge \omega_0}{\chi_\varphi^2}, \quad \varphi|_{t=0} = \varphi_0 \in \mathcal{P}_{\chi_0},$$

where $c_0$ is defined by

$$c_0 = \frac{2[\chi_0] \cdot [\omega_0]}{[\chi_0]^2}.$$

The J-flow was introduced by Donaldson [D1] in the setting of moment maps and
by Chen [Ch1] as the gradient flow of the J-functional which appears in his formula
for the Mabuchi energy. Smooth solutions to (1.1) exist for all time and are unique
[Ch2].

Under the assumption

$$c_0[\chi_0] - [\omega_0] > 0,$$

it was shown in [W1] that the solution to the J-flow converges smoothly to $\varphi_\infty$
solving the critical equation

$$2\chi_\varphi_\infty \wedge \omega_0 = c_0\chi_\varphi_\infty^2.$$

The fact that smooth solutions to (1.3) exist under the condition (1.2) was con-
jectured by Donaldson [D1] and proved by Chen by reducing the equation to the
complex Monge-Ampère equation solved by Yau [Y1]. In higher dimensions, it
was shown in [W2] that the flow converges under the cohomological assumption
$c_0[\chi] - (n-1)[\omega_0] > 0$. Necessary and sufficient conditions for convergence of the
J-flow in terms of $[\chi_0]$ and $\omega_0$ were found in [SW1].

In [FLM, FL1], convergence results were proved for generalizations of the J-flow
known as inverse $\sigma_k$-flows. In [FL2], Fang-Lai analyzed the behavior of the inverse
$\sigma_k$-flow on general Kähler classes for metrics with Calabi symmetry. The J-flow has
been investigated on Hermitian manifolds by Y. Li [LiY], and the critical equation

---

1Research supported in part by NSF grants DMS-08047524 and DMS-1105373. This work was
carried out while the second-named author was on leave from UC San Diego.
on Hermitian manifolds with boundary by Guan-Li\cite{GL}. An equation bearing strong similarities to the critical equation for the J-flow is the \textit{complex Hessian equation} (see for example\cite{LiS, B, H, HMW, Chi}); it has been studied intensely in the last few years, and the existence of solutions on compact Kähler manifolds was recently established by Dinew-Kołodziej\cite{DK}.

We now return to the discussion of the J-flow. In complex dimension two, the behavior of the J-flow was investigated\cite{FLSW} in the case where
\[
c_0[\chi_0] - [\omega_0] \geq 0,
\]
where $\beta \geq 0$ means that the cohomology class $\beta$ admits a smooth nonnegative representative. A uniform $L^\infty$ estimate for $\varphi$ was established, and it was shown that the J-flow converges smoothly to a singular Kähler metric away from a finite number of curves of negative self-intersection.

In this paper, we generalize the result of\cite{W1} in a different direction. We consider the case where $\omega_0$ is no longer a Kähler metric, but a closed (1,1) form satisfying a certain nonnegativity condition. More precisely, assume that we have a background Kähler metric $\hat{\omega}$ and an effective divisor $D$ on $M$ with associated line bundle $[D]$. Let $H$ be a fixed Hermitian metric on the line bundle $[D]$, and let $s$ be a holomorphic section of $[D]$ which vanishes exactly along $D$. Our assumption on $\omega_0$ is:
\begin{equation}
(1.4) \quad \omega_0 \text{ is a smooth closed (1,1) form with } \omega_0 \geq \frac{1}{c_0} s^2 H \hat{\omega} \quad \text{and} \quad \omega_0 - \rho R_H \geq \frac{1}{c_0} \hat{\omega},
\end{equation}
for some positive constants $C_0, \beta, \rho$. Here, $R_H = -dd^c \log H$ denotes the curvature form of the Hermitian metric $H$.

Clearly (1.4) holds if $\omega_0$ is Kähler. It is not uncommon for non-Kähler cohomology classes to admit a closed form $\omega_0$ satisfying (1.4). Indeed, we will see below that if $M$ is a minimal surface of general type then the canonical class, if it is not ample, is such an example. Also, it is well-known that such classes can be found on the boundary of the Kähler cone of blow-ups of Kähler manifolds, as discussed in\cite{SW2} for example.

We call the equation (1.1) with $\omega_0$ satisfying (1.4) the \textit{degenerate J-flow}. Now (1.1) is no longer a parabolic equation in general and we cannot expect to obtain smooth solutions. The main result of this paper is that there exists a unique “weak” solution to this degenerate parabolic equation, which converges to a “weak” solution of the critical equation. More precisely, define a space
\begin{equation}
P_{\chi_0} \text{weak} := \{ \varphi \in C^\infty(M \setminus D) \cap \text{PSH}_{\chi_0}(M) \cap L^\infty(M) \mid \chi_0 + dd^c \varphi > 0 \text{ on } M \setminus D \},
\end{equation}
where we are writing $D$ also for the subset of $M$ defined by the divisor $D$. Here $\text{PSH}_{\chi_0}(M)$ consists of upper semicontinuous functions $\varphi : M \to [-\infty, \infty)$ such that $\varphi + \psi_0$ is plurisubharmonic, where $\psi_0$ is a (smooth) local Kähler potential for $\chi_0$.

We have the following result.

\textbf{Theorem 1.1.} Let $M$ be a compact Kähler surface, with Kähler metrics $\chi_0$ and $\hat{\omega}$. Assume that $\omega_0$ satisfies (1.4) and assume that
\begin{equation}
c_0[\chi_0] - [\omega_0] > 0, \quad \text{for} \quad c_0 = \frac{2[\chi_0] \cdot [\omega_0]}{[\chi_0]^2}.
\end{equation}
For any smooth $\varphi_0 \in P_{\chi_0}$, there exists a unique solution $\varphi = \varphi(t) \in P_{\chi_0} \text{weak}$ of the degenerate J-flow
\begin{equation}
\frac{\partial}{\partial t} \varphi = c_0 - \frac{2\chi_0 \wedge \omega_0}{\chi_0^2} \quad \text{on } M \setminus D, \quad \varphi|_{t=0} = \varphi_0,
\end{equation}
with \( \sup_{M \setminus D} \left| \frac{\partial \varphi}{\partial t} \right| \) bounded (independent of \( t \)).

As \( t \to \infty \),

\[
\varphi(t) \xrightarrow{C^\infty_{\text{loc}}(M \setminus D)} \varphi_\infty,
\]

where \( \varphi_\infty \in \mathcal{P}_{\chi_0}^{\text{weak}} \) solves the critical equation

\[
(1.8) \quad 2\chi_\varphi \wedge \omega_0 = c_0 \chi_\varphi^2 \quad \text{on} \quad M \setminus D.
\]

Moreover, \( \varphi_\infty \in \mathcal{P}_{\chi_0}^{\text{weak}} \) is the unique solution of the critical equation up to the addition of a constant.

Note that \( \varphi_\infty \) coincides with the pluripotential solution of (1.8) on \( M \) in the sense of Bedford-Taylor (see [K3], for example).

We recall now the \( J \)-functional of Chen [Ch1]. Given a Kähler form \( \chi_0 \) and a closed \((1,1)\) form \( \omega_0 \), define the \( J \)-functional by

\[
(1.9) \quad J_{\omega_0, \chi_0}(\varphi) = \int_0^1 \int_M \dot{\varphi}_s (2\chi_\varphi \wedge \omega_0 - c_0 \chi_\varphi^2) \, ds, \quad \text{for} \quad \varphi \in \mathcal{P}_{\chi_0},
\]

where \( \varphi_s \) is a smooth path in \( \mathcal{P}_{\chi_0} \) between 0 and \( \varphi \). In the case where \( \omega_0 \) is Kähler, the \( J \)-flow is the gradient flow of the \( J \)-functional. A consequence of our main result is that the \( J \)-functional is uniformly bounded from below on the space \( \mathcal{P}_{\chi_0} \).

**Corollary 1.2.** As in Theorem 1.1, let \( M \) be a compact Kähler surface with Kähler metrics \( \chi_0 \) and \( \hat{\omega} \). Assume that \( \omega_0 \) satisfies (1.4) and that (1.6) holds. Then there exists a constant \( K \) depending only on the fixed data \( M, \omega_0, \chi_0 \) such that

\[
(1.10) \quad J_{\omega_0, \chi_0}(\varphi) \geq K, \quad \text{for all} \quad \varphi \in \mathcal{P}_{\chi_0}.
\]

This result has an immediate application to the Mabuchi energy functional, which we now explain. A well-known open problem in Kähler geometry is to determine which Kähler classes on \( M \) admit Kähler metrics of constant scalar curvature. The Yau-Tian-Donaldson conjecture relates this to a notion of stability in the sense of geometric invariant theory [Y2, T1, D2]. A related question is to ask instead for which Kähler classes is the Mabuchi energy functional *proper* (see Section 3 below for the definition). Indeed, according to a conjecture of Tian [T2], these questions are essentially equivalent, modulo some issues which arise if \( M \) admits holomorphic vector fields.

It was shown by Chen [Ch1] that if the canonical bundle \( K_M \) of \( M \) satisfies \( K_M > 0 \) then the Mabuchi energy is bounded below on all Kähler classes \([\chi_0]\) satisfying

\[
(1.11) \quad \left( \frac{2[\chi_0] \cdot K_M}{[\chi_0]^2} \right) [\chi_0] - K_M > 0.
\]

An alternative proof of this was given by the second-named author using the J-flow [W1]. Later, the authors observed [SW1] that under the same assumption (1.11), it follows from a result of Tian [T2] that in fact the Mabuchi energy is not just bounded below but proper. Moreover, we proved analogous results on manifolds \( M \) of any dimension with \( K_M > 0 \).

Fang-Lai-Song-Weinkove [FLSW] recently showed that the assumption (1.11) can be weakened to

\[
(1.12) \quad \left( \frac{2[\chi_0] \cdot K_M}{[\chi_0]^2} \right) [\chi_0] - K_M \geq 0,
\]
where $\sigma \geq 0$ means that the cohomology class $\sigma$ admits a smooth nonnegative representative.

In this paper, we instead allow $K_M$ to satisfy a more general nonnegativity condition than being ample. We assume that $K_M$ is big and nef, meaning that $K_M^2 > 0$ and $K_M \cdot C \geq 0$ for all curves $C$ on $M$. This is equivalent to saying that $M$ is a minimal surface of general type.

**Corollary 1.3.** Let $M$ be a minimal surface of general type. Then the Mabuchi energy is proper on all Kähler classes $[\chi_0]$ satisfying

$$
(1.13) \quad \left( \frac{2[\chi_0] \cdot K_M}{|\chi_0|^2} \right)[\chi_0] - K_M > 0.
$$

Thus one would expect constant scalar curvature Kähler metrics to exist in these classes. It is also expected that such classes are $K$-stable in the sense of [T1, D2]. In fact, it follows immediately from results of Panov-Ross (see the argument of [PR, Example 5.9]) that algebraic classes satisfying (1.13) are slope stable in the sense of Ross-Thomas [RT].

The main technical results are contained in Section 2. The idea is to replace the degenerate $(1,1)$-form $\omega_0$ with a Kähler form $\omega_{\varepsilon}$ for $\varepsilon > 0$ and obtain estimates for the J-flow away from $D$ which are independent of $\varepsilon$. As $\varepsilon \to 0$, we have $\omega_{\varepsilon} \to \omega_0$ and we obtain a solution of the degenerate J-flow (cf. results of Song-Tian [ST] in the case of the Kähler-Ricci flow). The key estimates are contained in Proposition 2.1. In Section 3, we prove Theorem 1.1 and its corollaries.

Finally, some words about notation. When we are given a $(1,1)$ form $\beta$, we will often define a tensor with components $\beta_{ij}$ by $\beta = \sqrt{-1} \beta_{ij} dz^i \wedge d\bar{z}^j$. An exception to this notation is that for a Kähler form $\omega$ we write $\omega = \sqrt{-1} g_{ij} dz^i \wedge d\bar{z}^j$, and similarly for $\omega_0, g_0$, etc. Given a positive definite $(1,1)$ form $\alpha$ and a $(1,1)$ form $\beta$, we write $tr_\alpha \beta$ for $\alpha^{\bar{j}i} \beta_{ij}$, where $(\alpha^{\bar{j}i})$ is the inverse of $(\alpha_{ij})$. We will often denote uniform constants by $C, C_0, C_1, C', C'', \ldots$ etc., which may differ from line to line.

The authors thank the referee for some helpful comments and suggestions.

2. Estimates for solutions of the J-flow

The degenerate J-flow (1.7) defined in the introduction is not a parabolic equation. We perturb the equation to make it parabolic.

Assume we are in the setting of Theorem 1.1 Write $\omega_{\varepsilon} = \omega_0 + \varepsilon \hat{\omega} > 0$ and define

$$
(2.1) \quad c_\varepsilon := \frac{2[\chi_0] \cdot [\omega_{\varepsilon}]}{|\chi_0|^2}.
$$

As $\varepsilon \to 0$, $c_\varepsilon \to c_0$. From (1.9), we may choose $\varepsilon_0 > 0$ sufficiently small so that for $\varepsilon \in [0, \varepsilon_0]$ we have

$$
(2.2) \quad c_\varepsilon [\chi_0] - [\omega_{\varepsilon}] > 0.
$$

Then consider the family of J-flows

$$
(2.3) \quad \frac{\partial}{\partial t} \varphi_\varepsilon = c_\varepsilon - \frac{2[\varphi_\varepsilon] \wedge \omega_{\varepsilon}}{[\varphi_\varepsilon]} \chi_\varphi, \quad \varphi_\varepsilon|_{t=0} = \varphi_0,
$$

parametrized by $\varepsilon \in (0, \varepsilon_0]$. By Chen’s result [Ch2], we know that there exists a solution to (2.3) on $M \times [0, \infty)$. The main result of this section is that we have uniform (independent of $\varepsilon$) $L^\infty$ bounds for $\varphi_\varepsilon, \dot{\varphi}_\varepsilon$ and $C^\infty$ estimates for $\varphi_\varepsilon$ away from $D$.!
Proposition 2.1. In the setting described above, there exists a uniform constant $C$ such that for all $t$ and $\varepsilon \in (0, \varepsilon_0]$,
\[
\|\varphi_{\varepsilon}\|_{L^\infty(M)} \leq C \quad \text{and} \quad \|\dot{\varphi}_{\varepsilon}\|_{L^\infty(M)} \leq C.
\]
Moreover, for any compact set $\Omega$ of $M \setminus D$ and $k > 0$, there exists $C_{\Omega,k} > 0$ such that
\[
\|\varphi_{\varepsilon}\|_{C^k(\Omega, \chi)} \leq C_{\Omega,k}.
\]
In order to prove the proposition, it suffices to establish the uniform $L^\infty$ estimates on $M$ and a second order estimate on $M \setminus D$.

Lemma 2.2. There exists a uniform constant $C$ such that for all $t$ and $\varepsilon \in (0, \varepsilon_0]$,
\[
\|\varphi_{\varepsilon}\|_{L^\infty(M)} \leq C.
\]

Proof. Put
\[
\alpha_{\varepsilon} := c_{\varepsilon}\chi_0 - \omega_\varepsilon > 0.
\]
We are allowed to assume without loss of generality that $\alpha_{\varepsilon}$ is Kähler and in addition, there exists $\delta > 0$ such that $\alpha_{\varepsilon} > \delta\chi_0$ for all $\varepsilon \in [0, \varepsilon_0]$. This is possible since the condition \([\text{L.0}]\) implies that we can find a smooth function $\eta$ with $c_0\chi_0 - \omega_0 + dd^c\eta > 2\delta\chi_0$ for a small $\delta > 0$. Shrinking $\varepsilon_0$ if necessary, we may assume that $c_{\varepsilon}\chi_0 - \omega_\varepsilon + dd^c\eta > \delta\chi_0$ for all $\varepsilon \in [0, \varepsilon_0]$, and we can estimate $\varphi_{\varepsilon} - \eta$ instead of $\varphi_{\varepsilon}$.

We begin by proving an $L^\infty$ estimate for $\varphi_{\varepsilon}$ which is independent of $\varepsilon$. We follow an argument similar to that in \([\text{FLSW}]\). It uses the trick of \([\text{Ch1}]\) of rewriting the critical equation as a complex Monge-Ampère equation, together with Yau’s $L^\infty$ estimate.

There exists a smooth solution $\psi_{\varepsilon}$ of the equation
\[
(\alpha_{\varepsilon} + c_{\varepsilon}dd^c\psi_{\varepsilon})^2 = \omega_\varepsilon^2, \quad \alpha_{\varepsilon} + c_{\varepsilon}dd^c\psi_{\varepsilon} > 0, \quad \sup_M \psi_{\varepsilon} = 0.
\]
Indeed, since
\[
[\alpha_{\varepsilon}]^2 = c_{\varepsilon}^2[\chi_0]^2 + [\omega_\varepsilon]^2 - 2c_{\varepsilon}[\chi_0] \cdot [\omega_\varepsilon] = [\omega_\varepsilon]^2,
\]
this follows from Yau’s theorem \([\text{Y.1}]\). Moreover,
\[
\|\psi_{\varepsilon}\|_{L^\infty} \leq C,
\]
for $C$ independent of $\varepsilon$. This follows from Yau’s original proof using Moser’s iteration, since $\alpha_{\varepsilon}$ is a smooth family of Kähler metrics which satisfy $\alpha_{\varepsilon} > \delta\chi_0$ and hence $\omega^2_\varepsilon/\alpha_{\varepsilon}^2$ is uniformly bounded from above. Here we are using the fact that the Sobolev constant, used in Yau’s iteration argument, remains bounded on any set of Riemannian metrics which is compact in the $C^0$ topology and has a uniform lower bound.

Note that Yau’s $C^\infty$ estimates for $\psi_{\varepsilon}$ may indeed depend on $\varepsilon$, but in what follows we only need uniformity in the $L^\infty$ estimate. Observe that
\[
\chi_{\psi_{\varepsilon}} = \chi_0 + dd^c\psi_{\varepsilon} > 0,
\]
since $\chi_{\psi_{\varepsilon}} = \frac{1}{c_{\varepsilon}}(\alpha_{\varepsilon} + c_{\varepsilon}dd^c\psi_{\varepsilon} + \omega_\varepsilon)$ and $\alpha_{\varepsilon} + c_{\varepsilon}dd^c\psi_{\varepsilon} > 0$.

We have
\[
\omega^2_{\varepsilon} = (c_{\varepsilon}\chi_{\psi_{\varepsilon}} - \omega_{\varepsilon})^2 = c_{\varepsilon}^2\chi_{\psi_{\varepsilon}}^2 - 2c_{\varepsilon}\chi_{\psi_{\varepsilon}} \cdot \omega_{\varepsilon} + \omega_{\varepsilon}^2,
\]
and hence $\chi_{\psi_{\varepsilon}}$ satisfies the critical equation $c_{\varepsilon}\chi_{\psi_{\varepsilon}}^2 = 2\chi_{\psi_{\varepsilon}} \cdot \omega_{\varepsilon}$. 

Now put $\theta_\varepsilon = \varphi_\varepsilon - \psi_\varepsilon$ and compute
\begin{equation}
\frac{\partial}{\partial t} \theta_\varepsilon = \frac{\partial}{\partial t} \varphi_\varepsilon = \frac{2\chi_{\varphi_\varepsilon} \wedge \omega_\varepsilon}{\chi^2_{\varphi_\varepsilon}} - \frac{2\chi_{\varphi_\varepsilon} \wedge \omega_\varepsilon}{\chi^2_{\varphi_\varepsilon}} = \int_0^1 \frac{d}{dv} \left( \frac{2\eta_v \wedge \omega_\varepsilon}{\eta^2_v} \right) dv,
\end{equation}
where $\eta_v = v\chi_{\psi_\varepsilon} + (1 - v)\chi_{\varphi_\varepsilon}$ for $v \in [0, 1]$. Define $\tau^v_{\ell k} = \eta^v_{jk} \eta^v_{\ell i} \left( g_\varepsilon \right)_{ij}$, which is positive definite, and compute
\begin{align}
\frac{\partial}{\partial t} \theta_\varepsilon &= \int_0^1 \left( \frac{d}{dv} \tau^v_{\ell k} (g_\varepsilon)_{ij} \right) dv \\
&= -\int_0^1 \eta^v_{k} \eta^v_{ij} \left( \frac{d}{dv} \eta_v \right)_{k} (g_\varepsilon)_{ij} dv \\
&= -\int_0^1 \tau^v_{\ell k} (\chi_{\psi_\varepsilon} - \chi_{\varphi_\varepsilon})_{k \ell} dv \\
&= \left( \int_0^1 \tau^v_{\ell k} dv \right) \partial_\ell \partial_\ell \theta_\varepsilon.
\end{align}

Since $\left( \int_0^1 \tau^v_{\ell k} dv \right)$ is a positive definite tensor, we apply the maximum principle to see that $\theta_\varepsilon$ is uniformly bounded by $\sup_M |\theta_\varepsilon|$ at $t = 0$. Since $\varphi_\varepsilon|_{t=0} = \varphi_0$ and $\psi_\varepsilon$ is uniformly bounded it follows that $\theta_\varepsilon$ is uniformly bounded independent of $\varepsilon$. Hence $\varphi_\varepsilon$ is uniformly bounded independent of $\varepsilon$. \qed

Next we estimate the time derivative of $\varphi_\varepsilon$. First some notation: define an operator $\tilde{\Delta}_\varepsilon := h_{ji} \partial_i \partial_j$, where $h_{ji} := \chi_{jp} \chi_{qi} \left( g_\varepsilon \right)_{pq}$. Then:

Lemma 2.3. There exists a uniform constant $C$ such that for all $t$ and $\varepsilon \in (0, \varepsilon_0]$,
\[ \| \varphi_\varepsilon \|_{L^\infty(M)} \leq C. \]
Hence we have
\begin{equation}
\chi_{\varphi_\varepsilon} \geq \frac{1}{C'} \omega_\varepsilon = \frac{1}{C'} (\omega_0 + \varepsilon \hat{\omega}),
\end{equation}
for a uniform $C' > 0$.

Proof. This follows immediately from the maximum principle as in [Ch2]. Indeed, differentiating (2.3) we obtain
\[ \frac{\partial}{\partial t} \varphi_\varepsilon = \tilde{\Delta}_\varepsilon \varphi_\varepsilon. \]
Then by the maximum principle, $\varphi_\varepsilon$ is bounded uniformly in time. Moreover, the bound is independent of $\varepsilon$. In particular, $\text{tr} \chi_{\varphi_\varepsilon} \omega_\varepsilon \leq C'$, and this gives (2.11). \qed

It is important to note Lemma 2.3 does not give a uniform bound for $\chi_{\varphi_\varepsilon}$ away from zero which is independent of $\varepsilon$. In particular, we have no a priori upper bounds for $\text{tr} \chi_{\varphi_\varepsilon} \hat{\omega}$ or $\text{tr} h_{ij} \hat{g} := \hat{h}^p_{ij} (\hat{g})_{pq}$.

Next we wish to prove an estimate for $\chi_{\varphi_\varepsilon}$. For ease of notation, we drop all subscripts $\varepsilon$ and write $\chi$ for $\chi_{\varphi_\varepsilon}$. Write $u = \text{tr} \omega \chi$. We denote by $\hat{R}_{\ell k i j}$ the curvature of $\hat{g}$, and raise indices using $\hat{g}$.

We first derive an evolution equation and differential inequality for $\log u$.
Lemma 2.4. The evolution equation of $\log u$ is given by

$$
\left( \frac{\partial}{\partial t} - \tilde{\Delta} \right) \log u = \frac{1}{u} \left( -h^{k} \tilde{R}_{k}^{\tau} \tilde{\chi}_{\tau} - \hat{g}^{j} h^{p} \tilde{\chi}^{p} \tilde{\nabla}_{j} \tilde{\nabla}_{\tau} \tilde{\chi}_{\tau} + 2 \text{Re} \left( \hat{g}^{j} \chi^{p} \tilde{\chi}^{p} \tilde{\nabla}_{j} \tilde{\nabla}_{\tau} \tilde{\chi}_{\tau} g_{k\tau} \right) - \hat{g}^{j} \chi^{p} \tilde{\nabla}_{j} \tilde{\nabla}_{\tau} g_{k\tau} + \chi^{p} \hat{R}_{p}^{q} g_{k\tau} + \frac{|\partial u|_{h}^{2}}{u} \right).
$$

(2.12)

Moreover, there exists a constant $C$ depending only on $\hat{g}$ and $\|g_{0}\|_{C^{2}(M,\hat{g})}$ such that

$$
\left( \frac{\partial}{\partial t} - \tilde{\Delta} \right) \log u \leq C \text{tr}_{h} \hat{g} + C \left( \text{tr}_{h} \hat{\omega} \right) (\text{tr}_{h} \hat{\omega}) + 2 \text{Re} \left( \chi^{p} \left( \frac{\partial u}{u^{2}} \right) \partial_{\tau} \text{tr}_{h} \hat{\omega} \right).
$$

Proof. For any fixed $p \in M$, we choose a holomorphic coordinate system centered at $p$ with the property that $(\partial_{k} \hat{g}_{\tau})|_{p} = 0$ for all $i, j, k$. Compute at $p$,

$$
\frac{\partial}{\partial t} \chi_{j} = \frac{\partial}{\partial t} \left( \hat{g}^{j} \partial_{\tau} \right) = -\hat{g}^{j} \chi^{p} \partial_{\tau} \left( \chi^{p} \hat{g}_{k\tau} \right)
$$

$$
= -\hat{g}^{j} \chi^{p} \partial_{\tau} \left( \chi^{p} \hat{g}_{k\tau} \right) + \chi^{p} \hat{g}_{k\tau} = \hat{g}^{j} \left( g_{k\tau} \chi^{p} \partial_{\tau} \right) + \chi^{p} \hat{g}_{k\tau}
$$

$$
= \hat{g}^{j} \left( g_{k\tau} \chi^{p} \partial_{\tau} \right) + \chi^{p} \hat{g}_{k\tau}.
$$

And

$$
\tilde{\Delta} \log u = \frac{\tilde{\Delta} u}{u} - \frac{|\partial u|_{h}^{2}}{u^{2}} = \frac{1}{u} \left( h^{k} \partial_{k} \partial_{\tau} \left( \hat{g}^{j} \chi_{j} \right) - \frac{|\partial u|_{h}^{2}}{u} \right)
$$

$$
= \frac{1}{u} \left( h^{k} \tilde{R}_{k}^{\tau} \tilde{\chi}_{\tau} + h^{k} \hat{g}^{j} \partial_{k} \partial_{\tau} \tilde{\chi}_{\tau} - \frac{|\partial u|_{h}^{2}}{u} \right),
$$

where $|\partial u|_{h}^{2} := h^{k} \partial_{k} \partial_{\tau} u$. Then (2.12) follows from these two equations, the Kähler condition for $\chi$ and the fact that in our coordinate system we have

$$
\hat{g}^{j} \chi^{p} \partial_{k} \partial_{\tau} g_{k\tau} = \hat{g}^{j} \chi^{p} \partial_{k} \partial_{\tau} g_{k\tau} - \hat{g}^{j} \chi^{p} \tilde{R}_{\tau}^{\tau} g_{k\tau} = \hat{g}^{j} \chi^{p} \partial_{k} \partial_{\tau} g_{k\tau} - \chi^{p} \hat{R}_{p}^{q} g_{k\tau}.
$$

To deal with the terms involving one derivative of $\chi$ we use a completing the square argument, which is formally similar to that of Cherrier [Chl] (see also [TW Proposition 3.1]). Compute

$$
K = \hat{g}^{j} \chi^{p} h^{k} B_{\hat{g}_{j}^{k}} \hat{B}_{\hat{g}_{j}^{k}} \geq 0,
$$

where

$$
B_{\hat{g}_{j}^{k}} = \tilde{\nabla}_{i} \chi_{j} - \chi_{j} \frac{\partial u}{u} - g_{ka} \chi_{k} \tilde{\nabla}_{a} g_{j}.
$$
We compute

\[
K = \tilde{g}^{\ell j} \chi^{\ell p} h^{ij} \nabla_i \chi_{jk} \nabla_j \chi_{\ell p} + \tilde{g}^{\ell j} \chi^{\ell p} h^{ij} \left( \frac{\partial_k u}{u} \right) \chi_{\ell p} \left( \frac{\partial_r u}{u} \right) \\
+ \tilde{g}^{\ell j} \chi^{\ell p} h^{ij} \tilde{g}^{*a} \chi^*_{bc} \nabla_i \chi_{\ell p} \nabla_j \chi^*_{bc} - 2 \text{Re} \left( \tilde{g}^{\ell j} \chi^{\ell p} h^{ij} \chi^*_{nc} \nabla_i \chi_{\ell p} \nabla_j \chi^*_{nc} \right) \\
- 2 \text{Re} \left( \tilde{g}^{\ell j} \chi^{\ell p} h^{ij} \nabla_i \chi_{\ell p} \nabla_j \chi^*_{nc} \right) + 2 \text{Re} \left( \tilde{g}^{\ell j} \chi^{\ell p} h^{ij} \chi^*_{nc} \nabla_i \chi_{\ell p} \nabla_j \chi^*_{nc} \right).
\]

Using the definition of $h^{ij}$ and the Kähler condition for $\chi$,

\[
K = \tilde{g}^{\ell j} \chi^{\ell p} h^{ij} \nabla_i \chi_{jk} \nabla_j \chi_{\ell p} + \frac{|\partial u|^2}{u} + \tilde{g}^{\ell j} \chi^{\ell p} h^{ij} g^{*a} \chi^*_{bc} g_{c,b} g_{a}^* \chi_{\ell p} \nabla_i \chi_{\ell p} (\nabla_j \chi_{\ell p}) \\
- 2 \text{Re} \left( \partial_k \left( \tilde{g}^{\ell j} \chi^{\ell p} \right) h^{ij} \partial_r u \right) - 2 \text{Re} \left( \tilde{g}^{\ell j} \chi^{\ell p} \chi^*_{nc} \nabla_i \chi_{\ell p} g^*_{a} \chi^*_{nc} \nabla_j \chi_{\ell p} \right) \\
+ 2 \text{Re} \left( \tilde{g}^{\ell j} \chi^{\ell p} \chi^*_{nc} \nabla_i \chi_{\ell p} \nabla_j \chi^*_{nc} \left( \frac{\partial_k u}{u} \right) \right) g^0 \chi^0 \nabla_i \chi^0 \nabla_j \chi^0 \\
= \tilde{g}^{\ell j} \chi^{\ell p} h^{ij} \nabla_i \chi_{jk} \nabla_j \chi_{\ell p} - \frac{|\partial u|^2}{u} + \tilde{g}^{\ell j} \chi^{\ell p} g^{*a} (\nabla_i \chi_{\ell p})(\nabla_j \chi_{\ell p}) \\
- 2 \text{Re} \left( \tilde{g}^{\ell j} \chi^{\ell p} \nabla_i \chi_{\ell p} \nabla_j \chi_{\ell p} \right) + 2 \text{Re} \left( \chi^{\ell p} \tilde{g}^{ij} \left( \frac{\partial_k u}{u} \right) \nabla_i \nabla_j \chi_{\ell p} \right).
\]

Combining this with (2.12) gives,

\[
\left( \frac{\partial}{\partial t} - \tilde{\Delta} \right) \log u = \frac{1}{u} \left\{ - h^{ij} \tilde{R}_{ij} \chi_{\ell j} - \tilde{g}^{ij} h^{\ell p} \chi^0 \nabla_i \chi_{\ell p} \nabla_j \chi^0 - K \\
+ \tilde{g}^{\ell j} \chi^{\ell p} g^{*a} (\nabla_i \chi_{\ell p})(\nabla_j \chi_{\ell p}) + 2 \text{Re} \left( \chi^{\ell p} \left( \frac{\partial_k u}{u} \right) \tilde{g}^{ij} (\nabla_i \chi_{\ell p})(\nabla_j \chi_{\ell p}) \right) \\
- \tilde{g}^{\ell j} \chi^{\ell p} \nabla_i \nabla_j \chi_{\ell p} + \chi^{\ell p} \tilde{R}^{ij} \chi_{\ell p} \right\} \\
\leq C \text{tr}_h \tilde{g} + 2 \text{Re} \left( \chi^{\ell p} \left( \frac{\partial_k u}{u^2} \right) \nabla_i \chi_{\ell p} \right).
\]

Indeed, to see the last inequality, we estimate

\[
\frac{1}{u} \left| h^{ij} \tilde{R}_{ij} \chi_{\ell j} \right| \leq C \text{tr}_h \tilde{g},
\]

and

\[
\frac{1}{u} \left| \tilde{g}^{\ell j} \chi^{\ell p} \nabla_i \nabla_j \chi_{\ell p} \right| + \frac{1}{u} \left| \chi^{\ell p} \tilde{R}^{ij} \chi_{\ell p} \right| + \frac{1}{u} \left| \tilde{g}^{\ell j} \chi^{\ell p} g^{*a} (\nabla_i \chi_{\ell p})(\nabla_j \chi_{\ell p}) \right| \leq C \left( \text{tr}_h \tilde{g} \right),
\]

for a constant $C$ depending only on $\tilde{g}$ and $\|g_0\|_{C^2(M,\tilde{g})}$. Note that $\text{tr}_h \tilde{g} \tilde{g}$ is uniformly bounded from below away from zero, but may blow up along $D$. This completes the proof of the lemma.

Next we prove the estimate on $\chi$.

**Lemma 2.5.** There exist uniform constants $C, \gamma, \gamma$, independent of $\varepsilon$, such that

\[
u = \text{tr}_\omega \chi \leq \frac{C}{|\xi|^2_F}.
\]
Proof. From the condition (2.7), we may choose uniform positive constants \( \eta, \delta \) and \( \sigma \) to be sufficiently small so that
\[
(2.13) \quad c \chi_0 - \omega - c \delta R_H > 3 \eta \omega,
\]
and
\[
(2.14) \quad \chi_0 - \delta R_H \geq \sigma \hat{\omega},
\]
where we write \( c = c_\varepsilon = 2[\chi_0] \cdot [\omega_\varepsilon]/[\chi_0]^2 \).

Define (cf. [Ts])
\[
\check{\varphi} = \varphi - \delta \log |s|^2_H.
\]
Note that \( \check{\varphi} \) is bounded from below, and tends to infinity along \( D \). Let \( A > 1 \) be a large constant to be determined later. Consider the evolution of the quantity
\[
Q = \log u - A \check{\varphi} + \frac{1}{\check{\varphi} + C_0},
\]
where we choose the uniform constant \( C_0 \) so that
\[
0 \leq \frac{1}{\check{\varphi} + C_0} \leq 1.
\]
This type of quantity was used by Phong-Sturm [PS] in their study of the degenerate complex Monge-Ampère equation (for its later use in a parabolic setting, see [TW]).

Note that \( Q \) achieves a maximum at each time \( t \) away from \( D \). Since \( \varphi \) is uniformly bounded, it suffices to bound \( Q \) from above at its maximum, as long as \( A \) is chosen uniformly.

Note that at a maximum of \( Q \) we have
\[
\frac{\partial_k u}{u} = \left( A + \frac{1}{(\check{\varphi} + C_0)^2} \right) \partial_k \check{\varphi}.
\]
Then at a maximum of \( Q \) we have, from Lemma 2.4
\[
\left( \frac{\partial}{\partial t} - \hat{\Delta} \right) Q \leq C \text{tr}_{\hat{g}} \hat{\omega} + \frac{C(\text{tr}_\chi \hat{\omega})(\text{tr}_\omega \hat{\omega})}{u} + \frac{2}{u} \text{Re} \left( \chi \hat{k} (A + \frac{1}{(\check{\varphi} + C_0)^2}) (\partial_k \check{\varphi}) \partial_k \text{tr}_\omega \hat{\omega} \right)
\]
(2.15)
\[
- \left( A + \frac{1}{(\check{\varphi} + C_0)^2} \right) \left( \frac{\partial}{\partial t} - \hat{\Delta} \right) \check{\varphi} - \frac{2}{(\check{\varphi} + C_0)^3} |\partial \check{\varphi}|^2 h.
\]
But from (1.4) and (2.11),
\[
(2.16) \quad \frac{C'(\text{tr}_\chi \hat{\omega})(\text{tr}_\omega \hat{\omega})}{u} \leq \frac{C''(\text{tr}_\chi \omega)(\text{tr}_\omega \hat{\omega})}{u|s|^{2\beta}_H} \leq \frac{C'''}{u|s|^{4\beta}_H}.
\]
Observe that at a maximum of \( Q \) we may assume that \( \frac{C''}{u|s|^{4\beta}_H} \leq 1. \) Indeed if not, then assuming that \( \delta A \geq 2\beta \), we have that \( \log u + A \delta \log |s|^2_H \leq C \) and it follows immediately that \( Q \) is bounded from above, which is what we need to show.

Next,
\[
\frac{2}{u} \text{Re} \left( \chi \hat{k} (A + \frac{1}{(\check{\varphi} + C_0)^2}) (\partial_k \check{\varphi}) \partial_k \text{tr}_\omega \hat{\omega} \right) \leq \frac{CA}{u} |\partial \check{\varphi}| \chi |\partial \text{tr}_\omega \hat{\omega}| \chi.
\]
But
\[
\frac{1}{u} |\partial \check{\varphi}|^2_\chi = \frac{1}{u} \chi \hat{k} \partial_i \check{\varphi} \partial_i \check{\varphi} \leq \chi \hat{k} \chi \hat{l} \partial_i \check{\varphi} \partial_i \check{\varphi} \partial_i \check{\varphi} \partial_i \check{\varphi} \leq \frac{C}{|s|^{2\beta}_H} \eta \hat{i} \partial_i \check{\varphi} \partial_i \check{\varphi} = \frac{C}{|s|^{2\beta}_H} |\partial \check{\varphi}|^2 h,
\]
and, using (2.11),

$$|\partial \text{tr} \omega|^2_\chi \leq \frac{C}{|s|^{2\beta}_H}.$$  

Hence

$$\frac{CA}{u} |\partial \tilde{\varphi}|_\chi |\partial \text{tr} \omega|_\chi \leq \frac{C' A}{\sqrt{u|s|^{2\beta}_H}} |\partial \tilde{\varphi}|_h$$

$$\leq 2 \frac{|\partial \tilde{\varphi}|^2_h}{(\tilde{\varphi} + C_0)^3} + \frac{C'' A^2 (\tilde{\varphi} + C_0)^3}{u|s|^{4\beta}_H}.$$  

Putting this together, we obtain

$$\frac{2}{u} \text{Re} \left( \chi^\kappa \left( A + \frac{1}{(\tilde{\varphi} + C_0)^2} \right) (\partial_k \tilde{\varphi}) \partial_k \text{tr} \omega \right) \leq 2 \frac{|\partial \tilde{\varphi}|^2_h}{(\tilde{\varphi} + C_0)^3} + 1,$$

since we may assume without loss of generality, by an argument similar to the one given above, that $C'' A^2 (\tilde{\varphi} + C_0)^3/(u|s|^{4\beta}_H) \leq 1$. Combining this with (2.15) and (2.16), we obtain at a maximum point of $Q$,

$$0 \leq \left( \frac{\partial}{\partial t} - \tilde{\Delta} \right) Q \leq C_1 \text{tr} \hat{g} + 2 - \left( A + \frac{1}{(\tilde{\varphi} + C_0)^2} \right) \left( \frac{\partial}{\partial t} - \tilde{\Delta} \right) \tilde{\varphi}.$$  

Now compute on $M \setminus D$,

$$\left( \frac{\partial}{\partial t} - \tilde{\Delta} \right) \tilde{\varphi} = c - \text{tr} \omega - \hat{h}^7_i \partial_i (\varphi - \delta \log |s|^{2}_H)$$

$$= c - 2 \chi^7_i g_{\gamma} + \hat{h}^7_i ((\chi_0)_i \gamma - \delta (R_H)_i \gamma)$$

$$= c - 2 \chi^7_i g_{\gamma} + \eta \hat{h}^7_i ((\chi_0)_i \gamma - \delta (R_H)_i \gamma)$$

$$+ \frac{(1 - \eta)}{c} \hat{h}^7_i (c (\chi_0)_i \gamma - c \delta (R_H)_i \gamma),$$

for $\eta > 0$ as in (2.13). From (2.14), we choose $A$ (depending only on $C_1, \eta$ and $\sigma$) sufficiently large so that

$$A \eta \hat{h}^7_i ((\chi_0)_i \gamma - \delta (R_H)_i \gamma) \geq C_1 \text{tr} \hat{g}.$$  

Then from this together with (2.17) and (2.18), we obtain

$$c - 2 \chi^7_i g_{\gamma} + \frac{(1 - \eta)}{c} \hat{h}^7_i (c (\chi_0)_i \gamma - c \delta (R_H)_i \gamma) \leq \frac{2}{A},$$

and hence from (2.13),

$$c - 2 \chi^7_i g_{\gamma} + \frac{(1 - \eta)(1 + 3\eta)}{c} \hat{h}^7_i g_{ij} \leq \frac{2}{A}.$$  

This implies that, shrinking $\eta$ if necessary,

$$c - 2 \chi^7_i g_{\gamma} + \frac{(1 + \eta)}{c} \hat{h}^7_i g_{ij} \leq \frac{2}{A}.$$  

Now choosing coordinates for which $g$ is the identity and $\chi$ is diagonal with entries $\lambda_1, \lambda_2$, we have

$$c + \frac{(1 + \eta)}{c} \sum_{i=1}^2 \frac{1}{\lambda_i^2} - 2 \sum_{i=1}^2 \frac{1}{\lambda_i} \leq \frac{2}{A}.$$
Completing the square as in [W2, SW1], we get
\[
\sum_{i=1}^{2} \left( \frac{\sqrt{c}}{\sqrt{1+\eta}} - \frac{\sqrt{1+\eta}}{\sqrt{c}\lambda_i} \right)^2 \leq \frac{2}{A} - c + \frac{2c}{1+\eta} = \frac{2}{A} + \frac{c(1-\eta)}{1+\eta}.
\]
We may assume that \( A \) is chosen large enough so that
\[
\frac{2}{A} \leq \frac{c(1-\eta)}{1+\eta},
\]
and thus
\[
\sum_{i=1}^{2} \left( \frac{\sqrt{c}}{\sqrt{1+\eta}} - \frac{\sqrt{1+\eta}}{\sqrt{c}\lambda_i} \right)^2 \leq c(1-\eta).
\]
Hence, for \( i = 1, 2 \),
\[
\frac{\sqrt{c}}{\sqrt{1+\eta}} - \frac{\sqrt{1+\eta}}{\sqrt{c}\lambda_i} \leq \sqrt{c(1-\eta)},
\]
which implies that
\[
\lambda_i \leq \frac{1+\eta}{c(1-\sqrt{1-\eta^2})}.
\]
Then
\[
\text{tr}_g \chi \leq C,
\]
at this maximum point of \( Q \). Hence \( \text{tr}_g \chi \leq C \) at this point, and we see that \( Q \) is bounded from above. This completes the proof. \( \square \)

The higher order estimates (2.5) follows immediately by applying the standard local parabolic theory (as in [SW1], for example). This completes the proof of Proposition 2.1.

3. Proof of the main theorem and corollaries

We can now prove the main results of the paper.

Proof of Theorem 1.1. From Proposition 2.1 we can find a sequence \( \varepsilon_j \to 0 \) such that \( \varphi_{\varepsilon_j} \) converges in \( C^\infty \) on compact subsets of \( (M\setminus D) \times [0, \infty) \). Define on \( M\setminus D \),
\[
\varphi = \lim_{j \to \infty} \varphi_{\varepsilon_j}.
\]
Then on \( (M\setminus D) \times [0, \infty) \), \( \varphi \) is smooth, satisfies \( \chi_0 + dd^c \varphi > 0 \) and solves the degenerate J-flow equation (1.7). Moreover, again from Proposition 2.1 \( \sup_{M\setminus D} |\varphi| \) and \( \sup_{M\setminus D} |\varphi| \) are uniformly bounded independent of \( t \). It is a standard result in pluripotential theory that a smooth function \( \varphi \) on \( M-D \) which satisfies \( \chi_0 + dd^c \varphi > 0 \) and \( \sup_{M-\Delta} |\varphi| \leq C \) can be extended uniquely to an element of \( \mathcal{P}_{\chi_0}^{\text{weak}} \) (see [K3] for example). Writing again \( \varphi \) for this function, we obtain the required solution \( \varphi \) to (1.7).

Now recall that the \( J \)-functional is defined on \( \mathcal{P}_{\chi_0} \) by (1.9). One can also write down an explicit formula:
\[
(3.1) \quad J_{\omega_0, \chi_0}(\varphi) = \int_M \varphi (\omega_0^w + \chi_0) \omega_0 - \frac{c_0}{3} \int_M \varphi (\chi_0^2 + \chi_0^w + \chi_0^w), \quad \varphi \in \mathcal{P}_{\chi_0},
\]
and this definition extends to \( \varphi \in \mathcal{P}_{\chi_0}^{\text{weak}} \). From the uniform \( L^\infty \) bound for the solution \( \varphi(t) \) of the degenerate J-flow, as argued in [FLSW], we see that
\[
(3.2) \quad J_{\omega_0, \chi_0}(\varphi(t)) \geq -C,
\]
for a uniform constant $C$ independent of $t$. In addition, $\mathcal{J}_{\omega_0, \chi_0}(\varphi(t))$ satisfies

$$
\frac{d}{dt}\mathcal{J}_{\omega_0, \chi_0}(\varphi(t)) = -\int_{M \setminus D} \varphi^2 \chi_0^2(t) \leq 0.
$$

Then it follows from the proof of Theorem 1.1 in [FLSW] that $\dot{\varphi}$ tends to zero in $C^\infty$ on compact subsets of $M \setminus D$.

Next, define the $\mathcal{I}$-functional on $\mathcal{P}_{\chi_0}^{\text{weak}}$ by

$$
\mathcal{I}_{\omega_0, \chi_0}(\varphi(t)) = \frac{1}{3} \int_M \varphi(\chi_0^2 + \chi_0^2 + \chi_0^2),
$$

and we see that $\mathcal{I}_{\omega_0, \chi_0}(\varphi(t)) = \mathcal{I}_{\omega_0, \chi_0}(\varphi_0)$ for all $t$. It follows from the same argument as in [FLSW] that as $t \to \infty$, the solution $\varphi(t)$ to the degenerate J-flow converges in $C^\infty$ on compact subsets of $M \setminus D$ to the unique $\varphi_{\infty} \in \mathcal{P}_{\chi_0}^{\text{weak}}$ satisfying the critical equation

$$
2\chi_{\varphi_{\infty}}^2 + \omega = 0 = 2\chi_{\varphi_{\infty}}^2 + \omega > 0
$$

on $M \setminus D$ subject to the normalization condition $\mathcal{I}_{\omega_0, \chi_0}(\varphi_{\infty}) = \mathcal{I}_{\omega_0, \chi_0}(\varphi_0)$. Indeed, to see this last uniqueness statement, observe that $\varphi_{\infty}$ must satisfy

$$
(\alpha_0 + c_0 dd^c \varphi_{\infty})^2 = \omega_{\infty}^2, \quad \alpha_0 + c_0 dd^c \varphi_{\infty} > 0
$$

on $M \setminus D$, for $\alpha_0 = c_0 \chi_0 - \omega_0 > 0$. Moreover, $0 \leq \varphi_{\infty}$ lies in $\mathcal{P}_{\chi_0}^{\text{weak}}$. But such solutions of the complex Monge-Ampère equation (3.3) are unique up to the addition of a constant $k$ by Corollary 4.2.

It remains to prove the uniqueness of the solution $\varphi(t)$ to the degenerate J-flow. We use an argument similar to one given in [ST]. Suppose there is another solution $\psi(t) \in \mathcal{P}_{\chi_0}^{\text{weak}}$ of (1.1) satisfying $\sup_{M \setminus D} |\dot{\psi}| \leq C$. Define $\theta_\delta = \varphi - \psi - \delta \log |s|^2_{H}$ on $M \setminus D$, which tends to infinity along $D$. For $v \in [0, 1]$, let $\eta_v = v\varphi + (1 - v)\chi_\psi$, $\tau_v = \eta_v^{-1} \eta_v^i (\theta_0)_i$. Computing as in (2.10), we have on $M \setminus D,$

$$
\frac{\partial}{\partial t} \theta_\delta = \left( \int_0^1 \tau_v^k dv \right) \partial_k \partial_\delta - \delta \left( \int_0^1 \tau_v^k dv \right) (R_H)_{k\ell}.
$$

Fix a time interval $[0, T]$. From the estimates $\sup_{M \setminus D} |\dot{\varphi}| \leq C$ and $\sup_{M \setminus D} |\dot{\psi}| \leq C$ we have the estimate $\eta_v \geq \frac{1}{C} \omega_0$ for a uniform constant $C > 0$. It follows that $(\tau_v^k) \leq C (\omega_0^k)$. Then

$$
\delta \left( \int_0^1 \tau_v^k dv \right) (R_H)_{k\ell} \leq C \delta g_0^k (R_H)_{k\ell} \leq \frac{2C\delta}{\rho}.
$$

since, from (1.4) we have $\omega_0 - \rho R_H > 0$ for a uniform $\rho > 0$.

Hence

$$
\frac{\partial}{\partial t} \theta_\delta \geq \left( \int_0^1 \tau_v^k dv \right) \partial_k \partial_\delta - \frac{2C\delta}{\rho},
$$

and so by the maximum principle, we have

$$
\theta_\delta \geq -A \delta t \geq -A \delta T,
$$

for a uniform constant $A$. It follows that $\varphi \geq \psi + \delta \log |s|^2_H - A \delta T$ and so $\varphi \geq \psi$ after letting $\delta \to 0$. The same argument shows that $\psi \geq \varphi$ and so $\varphi = \psi$. 

**Proof of Corollary 1.2** Given the discussion above, this is now immediate, since for any $\varphi_0 \in \mathcal{P}_{\chi_0}$, we have $\mathcal{J}_{\omega_0, \chi_0}(\varphi_0) = \lim_{t \to \infty} \mathcal{J}_{\omega_0, \chi_0}(\varphi(t))$. For the last equality, we have used Lemma 3.2 in [FLSW].
Proof of Corollary 1.3. The Mabuchi energy on the K"ahler class $[\chi_0]$ is defined by
\[
M_{\chi_0}(\varphi) = - \int_0^1 \int_M \dot{\varphi}_s (R_{\varphi_s} - \bar{R}) \chi_0^2 \varphi_s \, ds,
\]
where $\varphi_s$ is a smooth path in $\mathcal{P}_{\chi_0}$ between 0 and $\varphi$, and $\bar{R}$ is the average scalar curvature $\bar{R} = \frac{1}{\int_M \chi_0^2} \int_M R_{\chi_0} \chi_0^2$.

Let $E_{\chi_0}(\varphi) = \sqrt{-1} \int_M \partial \varphi \wedge \overline{\partial} \varphi \wedge (\chi_0 + \chi_\varphi)$. be the well-known Aubin-Yau functional (often denoted by $I_{\chi_0}$). Then we say the Mabuchi energy is proper [T2] if there exists an increasing function $f : [0, \infty) \to \mathbb{R}$, satisfying $\lim_{x \to \infty} f(x) = \infty$, such that for all $\varphi \in \mathcal{P}_{\chi_0}$,
\[
M_{\chi_0}(\varphi) \geq f(E_{\chi_0}(\varphi)).
\]
In fact, for the purposes of this corollary, we may take $f$ to be linear (cf. [PSSW]).

Since $K_M$ is big and nef, it is well-known that there exists a closed nonnegative $(1,1)$ form $\omega_0 \in c_1(K_M)$ satisfying (1.4). Indeed, one can take a Fubini-Study metric induced from the pluricanonical system $|mK_M|$ for sufficiently large $m$, and divide by $m$ to obtain a smooth closed nonnegative $(1,1)$ form $\omega_0 \in c_1(K_M)$. Note that since $\omega_0$ is the pull-back of a holomorphic (and hence smooth) map from $M$ into projective space, it is smooth everywhere on $M$. However, it is only positive definite on $M \setminus D$ where $D$ is the base locus. Moreover, $[\omega_0] - \rho c_1([D])$ is K"ahler for all $\rho > 0$ sufficiently small. Hence we can find a Hermitian metric $H$ on $[D]$ so that $\omega_0 - \rho R_H \geq \frac{1}{C_0} \omega$ for some fixed K"ahler metric $\omega$ and a positive constants $C_0, \rho$.

By definition of $\omega_0$, we have $\omega_0 \geq \frac{1}{C_0} |s|^2 H \omega$, for some positive $\beta$, after possibly increasing $C_0$.

The condition (1.13) implies that
\[
c_0 [\chi_0] - [\omega_0] > 0, \quad \text{for} \quad c_0 = \frac{[\chi_0] \cdot [\omega_0]}{[\chi_0]^2}.
\]
Hence we can apply Corollary 1.2 to see that $\mathcal{J}_{\omega_0, \chi_0}$ is uniformly bounded from below. The formula of Chen [Ch1] gives
\[
M_{\chi_0} = \mathcal{J}_{\omega_0, \chi_0} + \mathcal{F},
\]
for a certain functional $\mathcal{F}$, which is proper on $\mathcal{P}_{\chi_0}$ [SW1, T2]. This completes the proof. \qed

Remark 3.1. We remark that one can give an alternative proof of these two corollaries by elliptic methods. However, we believe that the degenerate J-flow is interesting in its own right, and may be important in extending these results to higher dimensions.
