1.Introduction

Spacecraft with flexible appendage is playing a key role in the development of the communication industry and remote sensing. To satisfy the space mission requirements, attitude maneuver is the basic operation of spacecraft. In the complex space environment, flexible appendage may vibrate under the effects of external disturbances and attitude maneuver. Flexible appendage generally possesses characteristics of light weight, low damping, and limited energy. These flexible characteristics make the vibration reduction slow down. However, the continuous vibration may reduce the operating efficiency of flexible spacecraft and even result in the destruction of flexible appendage. Hence, it is necessary to design a powerful and efficient controller to reduce the vibration of flexible appendage and simultaneously track the desired attitude.

In recent years, many research studies related to the modeling, vibration suppression, and attitude control of flexible spacecraft have been published. For the sake of control design, the models of flexible spacecraft are discretized in most of these works. Examples of these control schemes include fault tolerant control [1], optimal control [2], and positive position feedback control [3]. In [4], a variable structure control based on pulse-width pulse-frequency technology is designed to suppress the vibration of a flexible spacecraft with parameter uncertainties and input nonlinearity. In [5], using the distributed piezoelectric actuator technology, the authors propose a momentum exchange feedback control to stabilize flexible spacecraft. In [6], $H_\infty$ state feedback control is proposed for a flexible spacecraft in the presence of the multiobjective design requirements. The above control schemes are developed based on the discretization ordinary differential equation (ODE) models. However, model discretization may make the model inaccurate and bring spillover instability in control system although the ODE model provides the convenience in design control and appears brief in form [7, 8].

Compared with the control schemes designed from the ODE model [9–11], boundary control and distributed control are derived from the original partial differential equation (PDE) model, which can control all system modes
and eliminate the drawback of spillover instability. They have been widely used in the vibration reduction of flexible mechanical systems [12–14]. Synchronization control [15], backstepping boundary control [16], and cooperative control [17] are also effective for the distributed parameter system. In [18], the distributed fuzzy controller is adopted for a nonlinear distributed parameter system. It must be noted that distributed control is effective for the distributed parameter system. In [19], the authors design a mixed fuzzy/boundary control to ensure the practical stability of a nonlinear beam system. However, distributed control is more difficult to be implemented than boundary control in practice since it requires many distributed actuators and sensors. Hence, boundary control is regarded as a more practical control scheme. In [20, 21], the authors design the restricted boundary controls to stabilize the flexible aerial refueling hose system in the presence of varying length and speed. In [22], adaptive boundary control is designed to suppress the vibration of the flexible axially moving belt system with high acceleration/deceleration. Boundary barrier-based control is developed to regulate the elastic deformation of a flexible crane system with output constraint in [23]. In [24, 25], output feedback controls are developed to realize the target of vibration reduction for nonlinear flexible strings. For the nonuniform flexible wind turbine tower system, boundary control strategy is developed to reduce vibration via the generator electric torque in [26]. Although the great progress has been acquired for the boundary control design of flexible mechanical systems, the study of adaptive boundary control design for a flexible spacecraft system subject to external disturbances and parameter uncertainties is few. These results motivate us to design an adaptive boundary control scheme for the flexible spacecraft system.

External disturbance exists widely in practical engineering application. Many disturbance rejection technologies have been developed [27–29]. In [30], the signum function is considered to attenuate the impact of external disturbance, where the exact value of the upper bound of external disturbance is known. However, the signum function may bring the chattering in control input and the accurate information of external disturbance is hard to determine in practice. In [31], a common disturbance observer is developed to compensate for the effect of the bounded disturbance with the bounded rate, where the system structure physical parameters are certain. However, the robustness of the disturbance observers proposed in these papers is weak and the structure physical parameters of flexible spacecraft are uncertain. Hence, handling the effect of external disturbances in control design for a flexible spacecraft with uncertain parameters is still challenging. Mathematically, the proof of well posedness is one of the most important aspects of the stability analysis of the distributed parameter system. In [32], using the spectral analysis based on Lyapunov approach, the exponential stability of the Euler–Bernoulli beam system and the behavior of the solution of the closed-loop system are investigated. In [33–35], employing Gelerkin’s approximation method, the well posedness of the flexible beam system with the proposed feedback boundary control is discussed. To avoid the complicated and tedious functional calculations, the semigroup theory is used to prove the well posedness of the closed-loop system in this paper.

In this paper, we investigate the vibration reduction and attitude control of a flexible spacecraft with parameter uncertainties. The accurate dynamic model of flexible spacecraft is given by a set of coupled partial differential equation with ordinary differential equations. Two adaptive boundary control laws are designed to ensure the uniformly bounded stability of the closed-loop system. It should be noted that the proposed control scheme is derived from the original infinite dimensional dynamic model without any discretization, which can avoid spillover instability. Combining robust control strategy with two disturbance adaptive laws, the effect of external disturbances is attenuated exponentially in the negative feedback loop. The proposed disturbance rejection method can avoid chattering phenomenon and improve robust of the designed control scheme. The well posedness and uniform boundedness of the closed-loop system are proven under the semigroup theory and Lyapunov stability theory.

The paper is organized as follows. The model of flexible spacecraft is derived in Section 2. Adaptive boundary control scheme with disturbance adaptive laws is designed in Section 3. In Section 4, the well posedness and stability of the closed-loop system are discussed. The results of numerical simulations are given in Section 5. Finally, this paper is concluded in Section 6.

2. Dynamics Analysis

2.1. Dynamic Model. Figure 1 shows a typical model of flexible spacecraft. The model consists of a rigid hub with the radius $r$, which represents the spacecraft body, and an uniform flexible cantilever beam with the tip mass $m$, which represents the flexible appendage, such as solar array or any other flexible structure. $OXY$ and $oxy$ are defined as the inertial frame and the frame fixed on the hub, respectively. Denote $\omega(x,t)$ as the elastic deflection at point $x$ and time $t$ with respect to the $oxy$ frame. Define $\theta_d(t)$ as the attitude angle. $\theta_d$ is defined as the desired attitude. The tracking error is defined as $\theta_e(t) = \theta(t) - \theta_d$. $d_1(t)$ and $d_2(t)$ are the unknown boundary disturbances. $u_1(t)$ and $u_2(t)$ are the control inputs. The structure physical parameters of the flexible spacecraft system are listed as follows: EI is the bending stiffness of the flexible appendage, $c$ is the coefficient of viscous damping, $l$ is the length of the flexible appendage, $T$ is the tension, $\rho$ is the uniform mass per unit length, and $I_h$ denotes the hub inertia. For the sake of convenience in writing, the following notations are used throughout this paper: $(\cdot) = (\cdot)(x,t)$, $(\cdot) = \partial(\cdot)/\partial t$, $(\cdot) = \partial^2(\cdot)/\partial t^2$, $(\cdot) = \partial(\cdot)/\partial x$, $(\cdot)' = \partial(\cdot)/\partial x$, $(\cdot)'' = \partial^2(\cdot)/\partial x^2$, $(\cdot)''' = \partial^3(\cdot)/\partial x^3$, $(\cdot)'''' = \partial^4(\cdot)/\partial x^4$, $(\cdot)^{(0)} = \partial^0(\cdot)/\partial x^0$.

To obtain the PDE model of the flexible spacecraft system, the kinetic energy, potential energy, and virtual work can be expressed as follows:
Complexity

Lemma 1. Let \( w(x, t) \) be the continuously differentiable function with \( w(0, t) = 0 \); then, the following inequality holds [36]:

\[
\omega^2(x, t) \leq \int_0^t [w'(x, t)]^2 \, dx, \quad \forall t \in [0, \infty). \tag{6}
\]

**Lemma 2.** For bounded initial conditions, if there exists a \( C^1 \) continuous Lyapunov function \( V(x) > 0 \) satisfying \( a_1(\|x\|) \leq V(x) \leq a_2(\|x\|) \), such that \( V(x) \leq -bV(x) + c \), where \( a_1, a_2: \mathbb{R}^n \rightarrow \mathbb{R} \) are class \( \mathcal{K} \) functions and \( b, c > 0 \), then the solution \( x(t) \) is uniformly bounded [37].

**Assumption 1.** For the unknown boundary disturbances \( d_1(t) \) and \( d_2(t) \), we assume that there exist two positive constants \( \bar{d}_1 \) and \( \bar{d}_2 \), such that \( d_1(t) \leq \bar{d}_1 \) and \( d_2(t) \leq \bar{d}_2 \), \( \forall t \in [0, \infty) \). In practice, the energy of external disturbances \( d_1(t) \) and \( d_2(t) \) is finite. Thus, this assumption is reasonable.

### 3. Control Design

The control objectives of this paper are to reduce the vibration of flexible appendage and simultaneously trace the desired attitude. The block diagram given by Figure 2 describes the design procedure of the control strategy proposed in this paper for a flexible spacecraft system with external disturbances and parameter uncertainties. To stabilize the flexible spacecraft system described by (2)–(5), we design the following two adaptive boundary control laws:

\[ \begin{align*}
\begin{cases}
\dot{u}_1(t) = -k_3 u_a(t) - \tilde{m}[k_1 w'(l, t) - k_2 \tilde{w}'(l, t)] \\
\quad + \tilde{T} w'(l, t) - \tilde{E} \tilde{w}'(l, t) + u_d(t), \\
\dot{u}_2(t) = -k_3 \dot{u}_a(t) - k_4 S(t) - \gamma_1 \tilde{\theta}(t) + u_d(t),
\end{cases}
\end{align*} \tag{7}
\]

where \( \gamma_1, k_0, k_1, k_2, k_3, k_4 > 0, \tilde{m}, \tilde{T}, \tilde{E}, \) and \( \tilde{S} \) are the system parameter estimates, and the auxiliary signals \( u_a(t) \) and \( S(t) \) are given as follows:

\[ \begin{align*}
\begin{cases}
\dot{u}_a(t) = \dot{w}(l, t) + (r + l) \dot{\theta}(t) + k_1 \tilde{w}'(l, t) - k_2 \tilde{w}''(l, t), \\
S(t) = \gamma_1 \dot{\theta}(t) + \dot{\theta}(t),
\end{cases}
\end{align*} \tag{8}
\]

where \( u_d(t) \) and \( u_d(t) \) are two new input signals and are proposed as follows:

\[ \begin{align*}
\begin{cases}
\dot{u}_d(t) = -\frac{\tilde{d}_1(t) - u_a(t)}{\tilde{d}_1(t)} + \tau_1,
\dot{u}_d(t) = -\frac{\tilde{d}_2(t) - S(t)}{\tilde{d}_2(t)} + \tau_2.
\end{cases}
\end{align*} \tag{9}
\]

in which \( \tau_1, \tau_2 > 0 \) and \( \tilde{d}_1(t) \) and \( \tilde{d}_2(t) \) are the estimates of \( \bar{d}_1 \) and \( \bar{d}_2 \).
Adaptive laws

\[
\begin{align*}
\dot{\eta}_1 & = -\eta_1 \alpha_1 \dot{\eta}_1 (t) + u_a (t), \\
\dot{\eta}_2 & = -\eta_2 \alpha_2 \dot{\eta}_2 (t) + \eta \Phi (x, t), \\
\dot{\eta}_3 & = -\eta_3 \alpha_3 \dot{\eta}_3 (t) + \eta \Psi (x, t), \\
\dot{\eta}_4 & = -\eta_4 \alpha_4 \dot{\eta}_4 (t) + \eta \Theta (x, t), \\
\dot{\eta}_5 & = -\eta_5 \alpha_5 \dot{\eta}_5 (t) + \eta \zeta (x, t),
\end{align*}
\]

Figure 2: Design procedure of the adaptive boundary control scheme.

is an easier implemented control scheme than distributed control since it only requires the actuators and sensors at the system boundaries.

Remark 3. In practice, the exact values of boundary disturbances and the system structure physical parameters of flexible spacecraft are uncertain. To handle the unknown boundary disturbances, two disturbance adaptive laws (11) and (12) are developed, where we only require to ensure the existence of \( \overrightarrow{d}_1 \) and \( \overrightarrow{d}_2 \) and the chattering can be avoided. Thus, the proposed adaptive boundary control scheme (7) has better robustness than the common disturbance rejection technologies such as the signum function and disturbance observers.

4. Stability Analysis

4.1. Well-Posed Problem. In this part, the well posedness of the closed-loop system given by (2)–(5) is proven by employing the semigroup theory. The Hilbert space is introduced as the functional space. And then the closed-loop system can be rewritten to a first-order evolution equation. This result means that many results of the ordinary differential equation system can be applied in the proposed flexible spacecraft system.

For analyzing the well posedness, we introduce the following new variables:

\[
\begin{align*}
\Phi & = [\dot{\eta}_1, \dot{\eta}_2, \dot{\eta}_3, \dot{\eta}_4, \dot{\eta}_5]^T, \\
\Phi & = [\dot{\eta}_1, \dot{\eta}_2, \dot{\eta}_3, \dot{\eta}_4, \dot{\eta}_5]^T, \\
\Psi & = [k_1 \dot{\eta}_1, l_1, \dot{\eta}_2, \dot{\eta}_3, \dot{\eta}_4, \dot{\eta}_5]^T, \\
\zeta (x, t) & = \psi (x, t) + (r + x) \phi (x, t), \\
\zeta (x, t) & = \psi (x, t) + (r + x) \phi (x, t).
\end{align*}
\]

The flexible spacecraft system described by (2)–(5) can be transformed as the following closed-loop system:
\[
\begin{align*}
\rho \ddot{z} + EIz'' - Tz'' + c\dot{z} &= 0, \\
I_0 \ddot{\Theta}(t) &= -k_0 S(t) - \gamma_1 I_0 \dot{\Theta}(t) - k_0 \dot{\theta}_s(t) + EIz''(0,t) \\
- rEIz''(0,t) \\
+ d_2(t) + u_d(t) + T[z(l,t) - (r+l)\theta(t)], \\
m\dot{u}_a(t) &= -k_0 u_a(t) + d_1(t) + u_d(t) - \Psi^T \bar{\Phi}, \\
\theta(t) &= z'(0,t) = \frac{1}{r} z(0,t), \\
z''(l,t) &= 0. \\
\end{align*}
\]  

Define the state space as follows:

\[ H = H^2_2(0,l) \times L^2(0,l) \times R^2, \]  

where the space \( L^2 \) and \( H^2_2 \) are defined as

\[
L^2(0,l) = \left\{ f : [0,l] \rightarrow R \mid \int_0^l f^2 dx < \infty \right\},
\]

\[
H^2_2(0,l) = \left\{ f \in L^2(0,l) \mid \frac{\partial f}{\partial x}, \frac{\partial^2 f}{\partial x^2} \in L^2, f(0) = rf'(0), \frac{f''(l)}{l} = 0 \right\}.
\]  

The inner product of \( H \) is considered as

\[
\langle Y_1, Y_2 \rangle_H = \frac{\rho}{2} \int_0^l \psi_1\psi_2 dx + \frac{EI}{2} \int_0^l \left( \omega_1'' \right)^2 dx \\
+ \frac{T}{2} \int_0^l \left[ \omega_1' - \omega_1''(0) \right] \left[ \omega_1'' - \omega_1''(0) \right] dx + \frac{m}{2} u_a, u_a \\
+ \frac{I_0 S_1 S_2}{2} + \frac{k_0}{2\gamma_1^2} \left[ S_1 - \psi_1(0) \right] \left[ S_2 - \psi_2(0) \right] \\
+ \gamma_1 \rho \int_0^l (r + x)[(\varphi_1 + \psi_1) (\varphi_2 + \psi_2) \\
- \varphi_1' \varphi_2' - \psi_1 \psi_2] dx,
\]  

where \( Y_i = (\omega_i, \varphi_i, \psi_i, u_a, S_i) \) \( i = 1, 2. \)

We construct a linear operator as

\[
\begin{bmatrix}
\omega \\
\varphi \\
\psi \\
A \\
u_a \\
S
\end{bmatrix}
= \begin{bmatrix}
-\frac{T}{\rho} \\
-1 \\
-1 \\
-1 \\
-k_0 \frac{u_a}{m} \\
-k_0 \frac{\rho}{I_h} S + \zeta
\end{bmatrix},
\]

with its domain

\[ D(A) = \{ (\omega, \varphi, \psi, u_a, S)^T \in H \mid S = \gamma_1 \psi(0) + \frac{1}{r} \psi'(0), \]

\[ u_a = \psi(l) + k_0 [(\omega'(l) - \omega(0)] - k_0 \omega''(l)], \]

where

\[
\zeta = -\frac{k_0}{I_h} \psi'(0) + \frac{EI}{I_h} \omega''(0) - \frac{rEI}{I_h} \omega''(0) \\
+ \frac{T}{I_h} [(\omega(l) - (r + l)\omega'(0)].
\]  

Therefore, the closed-loop system (15) can be rewritten by the following evolutionary equation:

\[
\begin{cases}
\frac{dY(t)}{dt} = AY(t) + F(t), \\
Y(0) = Y_0,
\end{cases}
\]

where \( Y(t) = [z(\cdot, t), \omega_s(\cdot, t), \dot{z}(\cdot, t), u_a(t), S(t)]^T, Y_0 \) is the system initial state, and \( F(t) \) is given as follows:

\[
F(t) = \begin{bmatrix}
0 \\
0 \\
0 \\
\frac{1}{m} [d_1(t) + u_d(t) - \Psi^T \bar{\Phi}] \\
\frac{1}{I_h} [d_2(t) + u_d(t) - \frac{\gamma_1}{r} \psi'(0, t)]
\end{bmatrix}.
\]
For any $Y \in H$,
\[
\langle Y, AY \rangle_H \leq -M \left[ \int_0^1 \psi^2 \, dx + \int_0^1 [\omega' - \omega'(0)]^2 \, dx + \int_0^1 (\omega'')^2 \, dx + u_a^2 + \int_0^1 \psi^2 \, dx + S^2 + \partial_t^2 \right] \leq 0,
\]
(23)
where $M$ is a positive constant. Then, the operator $A$ given by (18) is dissipative in $H$.

We claim that $A^{-1}$ is compact on $H$. For any $Q = (q_1, q_2, q_3, q_4, q_5)^T \in H$, consider the solvability of equation $AY = Q$, $Y = (\omega, \phi, \psi, u_a, S)^T \in D(A)$. From (18), we can obtain the following equation:
\[
\begin{align*}
\psi(x) &= q_1(x), \\
\psi(x) &= q_2(x), \\
\frac{\partial}{\partial x} \frac{\partial}{\partial x} \left( \frac{E}{\rho} \right) (x) &= \frac{\partial}{\partial x} \frac{\partial}{\partial x} \left( \frac{E}{\rho} \right) (x) - \frac{\partial}{\partial x} \psi(x) = q_3(x), \\
\frac{k_0}{m} \psi &= q_4, \\
\frac{I_h}{k_4} S + \zeta &= q_5,
\end{align*}
\]
with corresponding boundary conditions
\[
\begin{align*}
\omega(0) &= \omega'(0), \\
\omega''(l) &= 0, \\
S &= \gamma_1 \psi'(0) + \frac{1}{r} \psi'(0), \\
u_a &= \psi(l) + k_1 [\omega'(l) - \omega'(0)] - k_2 \omega''(0).
\end{align*}
\]
Solving (24) leads to
\[
\begin{align*}
\omega(x) &= \frac{E}{\rho} \int_0^x e^{-b(x-y)} \int_0^y e^{-b} \int_0^z \rho q_3(s) + \gamma q_1(s) \, ds \, ds \, ds \\
\psi(x) &= \omega(x) - (r + x) \theta_d, \\
u_a &= \frac{-m}{k_0} \psi, \\
S &= \frac{I_h}{k_4} \psi - \frac{I_h}{k_4} \zeta,
\end{align*}
\]
where $b = \sqrt{T/El}$, $a_i, i = 1, \ldots, 4$, are the constants and their values are uniquely determined by the boundary conditions (25) and $\zeta$ can be computed by $\psi'(0), \omega(l), \omega'(0), \omega''(0)$, and $\omega'''(0)$. Thus, we can obtain that $A^{-1}$ is a compact operator using Sobolev embedding theorem.

Under Assumption 1, using (9), (11), and (12), we can conclude that $F(t)$ is locally Lipschitz continuous. Thus, the closed-loop system is well posed [38]. Finally, if $Y_0 \in H$, the closed-loop system has a unique solution, which can be expressed as
\[
Y = \Theta(t) Y_0 + \int_0^t \Theta(t-s) F(s) \, ds,
\]
(27)
where $\Theta(t)$ is the semigroup associated with $A$.

4.2. Uniform Boundedness. Consider the candidate Lyapunov function as
\[
E(t) = E_1(t) + E_2(t) + E_3(t) + E_4(t),
\]
(28)
where the energy term $E_1(t)$, auxiliary term $E_2(t)$, small crossing term $E_3(t)$, and estimation error term $E_4(t)$ are proposed as
\[
\begin{align*}
E_1(t) &= \frac{E}{2} \int_0^l \left[ \dot{\psi} + (r + x) \theta_d \right]^2 \, dx + \frac{T}{2} \int_0^l \left( \psi' \right)^2 \, dx \\
E_2(t) &= \frac{m^2 u_a^2(t)}{2} + \frac{3k_2^2}{2} + \frac{I_h}{2} \left[ \dot{u}_a^2(t) \right] \\
E_3(t) &= \gamma_1 \rho \int_0^l \left[ \dot{u}' + \theta_d(t) \right] \left[ \dot{u} + (r + x) \theta_d(t) \right] \, dx \\
E_4(t) &= \frac{1}{2} \left[ \dot{m}^2 + \dot{T}^2 + \dot{E}^2 + \dot{I}_h^2 \right] + \frac{1}{2} \left[ \dot{d}_1^2(t) + \dot{d}_2^2(t) \right].
\end{align*}
\]
(29)
Using Young’s inequality for $E_3(t)$ yields
\[
\begin{align*}
|E_3(t)| &= \gamma_1 \rho \int_0^l \left[ \dot{u} + (r + x) \theta_d(t) \right] \left[ \dot{u} + (r + x) \theta_d(t) \right] \, dx \\
&\leq \gamma_1 \rho \frac{r + l}{2} \int_0^l \left( \psi' \right)^2 \, dx + \frac{\gamma_1 \rho (r + l)}{\delta_1} \dot{d}_2^2(t) \\
&\quad + \gamma_1 \rho \frac{r + l}{2} \dot{d}_1(t) \int_0^l \left[ \dot{u} + (r + x) \theta_d(t) \right] \, dx \\
&\quad \leq \lambda \left[ E_1(t) + E_2(t) \right],
\end{align*}
\]
(30)
where $\delta_1, \lambda = \gamma_1 (r + l) \max \left[ \rho/T, 1 + 2 \delta_1, 2 \rho/\delta_1 k_3 \right] > 0$.

From (30), we can obtain
\[
-\lambda \left[ E_1(t) + E_2(t) \right] \leq E_3(t) \leq \lambda \left[ E_1(t) + E_2(t) \right].
\]
(31)
Therefore, we further obtain
\[ 0 < \theta_1 [E_1(t) + E_2(t) + E_4(t)] \leq E(t) \]
\[ \leq \theta_2 [E_1(t) + E_2(t) + E_4(t)], \]
where \( \theta_1 = 1 - \gamma_1 (r + l) \max \{ \rho/T, 1 + 2\delta_1, 2\rho/\delta_1 k_3 \} > 0 \) and \( \theta_2 = 1 - \gamma_1 (r + l) \max \{ \rho/T, 1 + 2\delta_1, 2\rho/\delta_1 k_3 \} > 1 \).

The following lemma is proposed as a useful tool to obtain our main results.

**Lemma 3.** The time derivative of the candidate Lyapunov function \( E(t) \) has an upper bound as
\[
\dot{E}(t) \leq -\theta E(t) + \epsilon,
\]
where \( \theta \) and \( \epsilon \) are two positive constants.

**Proof.** See Appendix A.

According to the above proposed lemmas, the stability theorem of the closed-loop flexible spacecraft system can be given as follows.

**Theorem 1.** For a flexible spacecraft system described by (2)–(5), under the proposed adaptive boundary control scheme (7), Assumption 1, and the bounded initial conditions, it can be obtained that the closed-loop flexible spacecraft system is uniformly bounded. The elastic deflection \( w(x, t) \) and tracking error \( \theta_e(t) \) remain in the compact sets \( \Omega \) and \( \Omega_e \) given by
\[
\Omega = \left\{ w(x, t) \in \mathbb{R} | \| w(x, t) \| \leq \sqrt{\frac{\gamma_1}{\beta_1}} \left[ E(0) + \frac{\epsilon}{\theta} \right], \quad \forall (x, t) \in [0, l] \times [0, \infty) \right\},
\]
\[
\Omega_e = \left\{ \theta_e(t) \in \mathbb{R} | \| \theta_e(t) \| \leq \sqrt{\frac{\gamma_2}{\beta_1}} \left[ E(0) + \frac{\epsilon}{\theta} \right], \quad \forall t \in [0, \infty) \right\}.
\]

**Proof.** See Appendix B.

### 5. Simulation

In order to demonstrate the feasibility and effectiveness of the proposed control scheme, the simulation is carried out employing the finite difference method. Let the initial conditions of the flexible spacecraft system be \( w(x, 0) = 0.6x \), \( w(x, 0) = 0, \forall x \in [0, l], \theta(0) = 0.4, \) and \( \dot{\theta}(0) = 0 \). The system parameters are listed as follows: \( \rho = 8 \text{ kg/m}, \quad l = 10 \text{ m}, \quad r = 0.5 \text{ m}, \quad m = 5 \text{ kg}, \quad EI = 120 \text{ Nm}^2, \quad T = 10 \text{ N}, \quad I_4 = 300 \text{ Ns/m}, \) and \( c = 0.0001 \text{ kg/ms} \). The external boundary disturbances are given as
\[
\begin{align*}
\begin{cases} 
    d_1(t) = \sin(0.1\tau t) + \sin(0.2\tau t), \\
    d_2(t) = \cos(0.1\tau t).
\end{cases}
\end{align*}
\]

The elastic deflection and attitude angle of the flexible spacecraft system without control are shown in Figures 3 and 4, respectively. Figures 5 and 6 display the deflection and attitude angle of the flexible spacecraft with the proposed adaptive boundary control scheme (7), respectively. Corresponding control inputs are described by Figure 7, where the control parameters are selected as follows: \( k_0 = 10, k_1 = 1, k_2 = 12, k_3 = 6000, \) and \( k_4 = 100 \). In addition, the estimates of upper bounds of boundary disturbances are shown in Figure 8. Figure 9 depicts the estimates of system parameters.

From Figures 3 and 4, it can be observed that the deflection \( w(x, t) \) is quite large and the attitude angle \( \theta \) widely exceeds the desired attitude \( \theta_d = 0.2 \text{ (rad)} \). From Figures 5 and 6, it is clear that the proposed adaptive boundary control scheme (7) can reduce effectively the deflection of flexible appendage and track the desired attitude after 20 s. These imply that great performances of tracking attitude and vibration reduction can be obtained based on the designed control scheme. From Figure 8, the control scheme proposed in this paper can stabilize the flexible spacecraft system in spite that the estimation error values of upper bounds of boundary disturbances cannot converge completely to zero. It can conclude from Figure 9 that the estimates of system

parameters converge to the neighborhood of their true values.

6. Conclusion

In this paper, the control problems of vibration suppression and tracking attitude for a flexible spacecraft system subject to external disturbances and parameter uncertainties have been addressed. We have designed an adaptive boundary control scheme (7) to reduce the elastic deflection of flexible appendage and guarantee the convergence of the tracking error of attitude angle. Two disturbance adaptive laws (11) and (12) and adaptive laws (10) have been developed to eliminate the impacts of unknown boundary disturbances and parameter uncertainties. The well posedness and uniform boundedness of the closed-loop system have been proven. The simulation results have illustrated the effectiveness of the proposed control scheme.

It is worth mentioning that the proposed control scheme can avoid the problem of spillover instability and control all system modes since it is designed based on the original PDE model. In addition, the proposed control scheme is relatively practical control strategy since it is easy to be implemented by sensors and actuators embedded at the system boundaries. The proposed adaptive boundary scheme has great robustness for the unknown external disturbance. In future, we will investigate the other advanced control schemes such as fuzzy control and active disturbance rejection control to stabilize the flexible spacecraft system studied in this paper.

Appendix

Proof of Lemma 3:

Taking the time derivative of (28) results in

\[ \dot{E}_1(t) = \dot{E}_1(t) + \dot{E}_2(t) + \dot{E}_3(t) + \dot{E}_4(t). \]  

(A.1)

Differentiating \( E_1(t) \) and then substituting the governing equation (3), we have

\[ \dot{E}_1(t) = A_1 + A_2 + A_3, \]

(A.2)

where \( A_1, A_2, \) and \( A_3 \) are defined as

\[
\begin{align*}
A_1 &= T \int_0^l \dot{\omega} \dot{w} \, dx, \\
A_2 &= EI \dddot{w} \dddot{w} \, dx, \\
A_3 &= \int_0^l \left[ \dddot{w} + (r + x) \dddot{\vartheta}(t) \right] \left[ T \dddot{w} - EI \dddot{w} \right] \, dx \\
&\quad + c \int_0^l \left[ \dddot{w} + (r + x) \dddot{\vartheta}(t) \right]^2 \, dx.
\end{align*}
\]

(A.3)
Applying integration by parts for $A_1$ and $A_2$ leads to

$$A_1 = T \left[ w''|_{x=0}^l - \int_0^l w'' \, dx \right]$$

$$= -T \int_0^l w'' \, dx + Tw' (l, t) \dot{w} (l, t),$$

$$A_2 = EI \left[ \frac{w'}{r} |_{x=0}^l - \int_0^l \frac{w'}{r} \, dx \right]$$

$$= EI \left[ \frac{w'}{r} |_{x=0}^l - \frac{w'' r}{r^3} |_{x=0}^l + \int_0^l \frac{w''}{r} \, dx \right]$$

$$= EI \int_0^l \frac{w''}{r} \, dx - EI \dot{w} (l, t) w'' (l, t).$$

Substituting (A.4) and (A.5) into (A.2) yields

$$\dot{E}_1 (t) = -c \int_0^l \left[ w (r + x) \dot{\theta} (t) \right]^2 \, dx$$

$$+ [\dot{w} (l, t) + (r + l) \dot{\theta} (t)] [Tw' (l, t) - EIw'' (l, t)]$$

$$+ \dot{\theta} (t) [rEIw'' (0, t) - EIw'' (0, t) - Tw (l, t)].$$

Differentiating $E_2 (t)$ with respect to time and substituting (7) yields

$$\dot{E}_2 (t) = -k_2 w_2 (t) - k_2 s^2 (t) - y_1 k_3 \dot{\theta} (t) - y_1 \overline{T}_s (t) \dot{\theta} (t)$$

$$+ u_a (t) [u_d (t) + d_1 (t)] + S (t) [u_d (t) + d_2 (t)]$$

$$+ S (t) [Tw (l, t) + EIw'' (0, t) - rEIw'' (0, t)]$$

$$+ u_a (t) \left[ Tw (l, t) - EIw'' (l, t) - m (k_1 \dot{w} (l, t)$$

$$- k_2 w'' (l, t)) \right].$$

Differentiating $E_3 (t)$, we have

$$\dot{E}_3 (t) = y_1 \rho \int_0^l (r + x) \left[ w' + \dot{\theta} (t) \right] \left[ w + (r + x) \dot{\theta} (t) \right] \, dx$$

$$+ y_1 \rho \int_0^l (r + x) \left[ w' + \dot{\theta} (t) \right] \left[ \dot{w} + (r + x) \dot{\theta} (t) \right] \, dx$$

$$+ y_1 \rho \int_0^l (r + x) \left[ w' + \dot{\theta} (t) \right] \left[ w + (r + x) \dot{\theta} (t) \right] \, dx.$$

Utilizing integration by parts derives

$$y_1 \rho \int_0^l (r + x) \left[ w' + \dot{\theta} (t) \right] \left[ w + (r + x) \dot{\theta} (t) \right] \, dx$$

$$= y_1 \rho (r + l) \left[ w (l, t) + (r + l) \dot{\theta} (t) \right]^2$$

$$- y_1 \rho (r + l) \left[ \frac{w (l, t) + (r + l) \dot{\theta} (t)}{2} \right]^2 - y_1 \rho \frac{(r + l)^2}{2} \dot{\theta} (t)^2$$

$$- y_1 \rho \frac{r + l}{2} \int_0^l \left[ \dot{w} + (r + x) \dot{\theta} (t) \right] \, dx.$$

Substituting the governing equation (3), we obtain

$$y_1 \rho \int_0^l (r + x) \left[ w' + \dot{\theta} (t) \right]$$

$$\cdot [\dot{w} + (r + x) \dot{\theta} (t)] \, dx = I_1 + I_2 + I_3 + I_4,$$

in which

$$I_1 = y_1 T \int_0^l (r + x) w' \, dx,$$

$$I_2 = -y_1 EI \int_0^l (r + x) w'' \, dx,$$

$$I_3 = -y_1 c \int_0^l (r + x) w \left[ w' + (r + x) \dot{\theta} (t) \right] \, dx,$$

$$I_4 = y_1 \int_0^l (r + x) \dot{\theta} (t) \left[ Tw'' - EIu'' \right] \, dx$$

$$\left. -yc_1 \theta (t) \int_0^l (r + x) [\dot{w} + (r + x) \dot{\theta} (t)] \, dx.\right.$$
where the proper parameters $\gamma_i$, $k_i$ ($i = 0, 1, 2, 3, 4$), and $\delta_j$ ($j = 1, \ldots, 6$) are chosen to satisfy the following conditions:

\[\begin{align*}
\gamma_1 &= c + \frac{\rho \epsilon}{2} - \frac{y_i (r + \bar{d})}{2} - \frac{y_i c \delta_1}{2}, \\
\gamma_2 &= T - (r + \bar{d})c > 0, \\
\gamma_3 &= k_0 - \frac{T}{2k_1} > 0, \\
\gamma_4 &= k_3 - \frac{T(r + \bar{d})}{\delta_2} - \frac{\text{EI}(r + \bar{d})}{\delta_3} - \frac{c}{\delta_4} > 0, \\
\gamma_5 &= \frac{T}{2k_1} - \frac{y_i \rho (r + \bar{d})}{2} - \frac{|k_2 T - k_1 \text{EI}|}{k_1 \delta_5} > 0, \\
\gamma_6 &= \frac{Tk_1}{2} - |k_2 T - y_1 (r + \bar{d})\text{EI}|\delta_6 - y_1 (r + \bar{d})T(1 + 2\delta_2) > 0, \\
\gamma_7 &= \frac{Tk_1^2}{2k_1} - \frac{|k_2 T - k_1 \text{EI}|\delta_5}{k_1} - y_1 (r + \bar{d})\text{EI}\delta_3, \\
\gamma_8 &= \frac{|k_2 T - y_1 (r + \bar{d})\text{EI}|}{\delta_6} > 0, \\
\theta_3 &= \min \left\{ \frac{2\nu_1 \nu_2}{\rho} \frac{2k_1}{h}, \frac{2\nu_3}{m}, \frac{2\nu_3}{h}, \frac{2\nu_3}{m}, \frac{\eta_1, \eta_2, \eta_3,}{\eta_1, \sigma_1, \sigma_2} > 0, \\
\epsilon &= \frac{\eta_2 m^2}{2} + \frac{\eta_3 T^2}{2} + \frac{\eta_5 \text{EI}^2}{2} + \frac{\eta_4 T^2}{2} + \frac{\sigma_2 T^2}{2} + \frac{\sigma_1 T^2}{2} + \tau_1 + \tau_2. \\
\end{align*}\]

According to (32) and (A.18), we further obtain

\[\bar{E}(t) \leq -\theta E(t) + \epsilon, \quad (A.20)\]

where $\theta = \theta_3/\theta_2 > 0$.

**Proof of Theorem 1:**

From Lemma 3, multiplying both sides of (33) by $\epsilon^\theta$ yields

\[\frac{\partial (E(t)\epsilon^\theta)}{\partial t} \leq \epsilon \epsilon^\theta. \quad (B.1)\]

Integrating the above inequality, we have

\[E(t) \leq \left[ E(0) \frac{\epsilon^{\theta}}{\theta} \right] e^{-\epsilon t} + \frac{\epsilon^{\theta}}{\theta} E(0) e^{-\epsilon t} + \frac{\epsilon}{\theta} \quad (B.2)\]
system is uniformly bounded. Inequality (B.2) implies that \( E(t) \) is bounded. Applying Lemma 1, (29), and (32) results in

\[
\begin{cases}
\dot{w}(x,t) \leq l \int_{l}^{0} (w')^2 \, dx \leq \varrho_1 E_1(t) \leq \frac{\varrho_1}{\varrho_1} E(t), \\
\dot{\theta}_c(t) \leq \varrho_2 E_2(t) \leq \frac{\varrho_2}{\varrho_1} E(t), \\
\overline{\varrho}_1^2, \overline{\varrho}_1^2, \overline{\varrho}_1^2, \overline{\varrho}_1^2 \leq 2 E_4(t) \leq \frac{2}{\varrho_1} E(t), \\
\overline{\varrho}_4^2, \overline{\varrho}_4^2 (t) \leq 2 E_4(t) \leq \frac{2}{\varrho_1} E(t),
\end{cases}
\]

where \( \varrho_1 = 2l/T > 0 \) and \( \varrho_2 = 2/k_1 \).

Substituting (B.2) into (B.3) leads to

\[
|w(x,t)| \leq \frac{\varrho_1}{\varrho_1} \sqrt{E(0) - \frac{\varepsilon}{\varrho_1}} e^{-\varrho_1 t} + \frac{\varepsilon}{\varrho_1}, \quad \forall 0 < x \leq l, \forall t \geq 0,
\]

\[
|\theta_c(t)| \leq \frac{\varrho_2}{\varrho_1} \sqrt{E(0) - \frac{\varepsilon}{\varrho_1}} e^{-\varrho_1 t} + \frac{\varepsilon}{\varrho_1}, \quad \forall t \geq 0,
\]

\[
|\bar{m}|, |\overline{\varrho}_1|, |\overline{\varrho}_1|, |\overline{\varrho}_1|, |\overline{\varrho}_1|, |\overline{\varrho}_1|, |\overline{\varrho}_1|, \leq \frac{2}{\varrho_1} \sqrt{E(0) - \frac{\varepsilon}{\varrho_1}} e^{-\varrho_1 t} + \frac{\varepsilon}{\varrho_1}, \quad \forall t \geq 0.
\]

According to Lemma 2, we can get that the closed-loop system is uniformly bounded. The error signals \( \bar{m}, \overline{\varrho}_1, \overline{\varrho}_1, \overline{\varrho}_1, \overline{\varrho}_1, \overline{\varrho}_1, \overline{\varrho}_1(t), \) and \( \overline{\varrho}_1(t) \) are uniformly bounded. \( w(x,t) \) and \( \theta_c(t) \) remain in the compact sets.
