ABSTRACT

Brain single photon emission computed tomography (SPECT) is a well-established and reliable method to assess brain function through measurement of regional cerebral blood flow (rCBF). It can be used to define a patient’s pathophysiological status when neurological or psychiatric symptoms cannot be explained by anatomical neuroimaging findings. Though there is ample evidence validating brain SPECT as a technique to track human behavior and correlating psychiatric disorders with dysfunction of specific brain regions, only few psychiatrists have adopted brain SPECT in routine clinical practice. It can be utilized to evaluate the involvement of brain regions in a particular patient, to individualize treatment on basis of SPECT findings, to monitor the treatment response and modify treatment, if necessary. In this article, we have reviewed the available studies in this regard from existing literature and tried to present the evidence for establishing the clinical role of brain SPECT in major psychiatric illnesses.

Keywords: Brain perfusion, psychiatric disorders, regional cerebral blood flow, single photon emission computed tomography

INTRODUCTION

Brain single photon emission computed tomography (SPECT) is a well-established and reliable method for evaluating brain function through measurement of regional cerebral blood flow (rCBF).[1] It is being utilized for detection of various neurodegenerative diseases and their management for several years. Brain SPECT can be used to define a patient’s pathological status when neurological or psychiatric symptoms cannot be explained by structural neuroimaging findings. Though there is ample evidence in the literature validating brain SPECT as a promising technique to track human behavior and correlating psychiatric disorders with dysfunction of specific brain regions, it is rarely utilized technique in routine psychiatric practice. Renowned medical bodies like the American College of Radiology, the Society of Nuclear Medicine and the European Society of Nuclear Medicine have published evidence-based guidelines for using brain SPECT to improve patient care. Commonly accepted clinical indications for brain SPECT include: Dementia (early diagnosis, differentiation from normal ageing, and differential diagnosis of Alzheimer’s disease from other neurodegenerative diseases), epilepsy (localization of epileptic focus by ictal and interictal studies), movement disorders, traumatic brain injury, cerebrovascular diseases, brain tumor and brain infections.[2-4] Nearly two decades back, Holman and Devous in their study, highlighted brain SPECT as a powerful window into the function of the brain and asserted it as a promising tool which could become an important component of the routine clinical evaluation of patients with neurological and psychiatric diseases.[5] A consistently growing body of research supports brain SPECT’s clinical utility. In 1996, Vasile concluded that, the clinical utility of SPECT in neuropsychiatry is well-established.[6] Camargo reviewed the utility of brain SPECT in 2001 and demonstrated its role in obsessive-compulsive disorder (OCD), Gilles de la Tourette’s syndrome, schizophrenia, depression, panic disorder, and drug abuse, in addition to common neurological indications.[7] However, despite the evidence relevant to diagnosis and treatment, only few psychiatrists have adopted brain SPECT or other functional neuroimaging techniques in...
routine clinical practice. Brain SPECT can be utilized to evaluate the involvement of specific brain regions in different patients, to individualize the treatment, for monitoring the treatment response and to modify treatment, when warranted. Though specific perfusion patterns for various psychiatric diseases have not been definitely recognized, perfusion and receptor imaging findings may be used as an additional diagnostic tool to guide clinicians searching for a definitive diagnosis. In this review article we have tried to consolidate the facts from existing literature and our own clinical experience, as to the kind of role brain SPECT can play in different psychiatric diseases.

**BRAIN PERFUSION SINGLE PHOTON EMISSION COMPUTED TOMOGRAPHY-TECHNICAL OVERVIEW**

**Radiopharmaceuticals**

The tracers used for brain perfusion SPECT are technetium-99m- hexamethylpropyleneamineoxime ($^{99m}$Tc-HMPAO) and technetium-99m-ethylcysteinate dimer ($^{99m}$Tc-ECD). The main differences between $^{99m}$Tc-HMPAO and $^{99m}$Tc-ECD relate to their *in vitro* stability, uptake mechanism, and dosimetry. $^{99m}$Tc-HMPAO is highly unstable *in vitro* and high radiochemical purity must be assured before injection. Stabilized forms of $^{99m}$Tc-HMPAO allow easier labeling and improvement of image quality by reducing background activity. By contrast, $^{99m}$Tc-ECD is stable up to at least 4 h *in vitro*, and freshly eluted $^{99m}$Tc is not required. Higher gray-matter-to-white-matter ratio, contributes to the better image quality obtained with $^{99m}$Tc-ECD. Although both of tracers are distributed proportionally to rCBF, their retention is not completely linear with rCBF because of an initial back diffusion. High blood flow may be underestimated and low blood flow may be overestimated with both tracers. In normal brain tissue, the kinetic properties are similar for both the perfusion agents. They enter the brain cells because of their lipophilic nature and remain there because of conversion into hydrophilic compounds. However, in patients with brain disease, the distribution of these compounds may differ because of the biochemistry of lipophilic-to-hydrophilic conversion. Although a metabolic process of de-esterification accounts for hydrophilic conversion of $^{99m}$Tc-ECD, instability of the lipophilic form have been proposed for $^{99m}$Tc-HMPAO. A perfusion-metabolic (de-esterification) coupling is needed in case of $^{99m}$Tc-ECD to be trapped within cell, whereas only perfusion matters in $^{99m}$Tc-HMPAO. Thus, $^{99m}$Tc-ECD would have a predominant cellular-metabolic uptake, and $^{99m}$Tc-HMPAO would reflect blood flow arrival to cerebral regions.

**Patient preparation**

Before arrival, patients should be instructed to avoid, if possible, caffeine, alcohol, or other drugs known to affect cerebral blood flow (CBF). Brain perfusion is sensitive to neuronal activities, hence, tracer injection to be done in a quiet room and no interaction with patients at this time is desirable, to avoid any sensorial and cognitive stimuli. To avoid head movement during scanning (20-30 min), the patient should be comfortable and relaxed. The uncooperative patients (those with severe cognitive impairment or with loss of insight) may need sedation. Tracer injection must precede sedation to avoid sedation-induced blood flow changes. Appropriate positioning is needed to keep the collimators as close as possible to the patient's head and to get entire brain within the center of field of view.

**Acquisition system and postprocessing software**

Because of the small size of important anatomically and functionally independent cerebral structures, spatial resolution is the main concern in brain imaging. A good compromise is to fit a general purpose rotating camera with fan beam collimator. Addition of computed tomography scan improves the quality of images by attenuation correction and structural correlation. Software applications are available for image processing to quantify the results in terms of rCBF for each brain functional area. Many of them have the features to compare with normal population database and provide statistical parametric mapping, so that one can easily recognize the abnormally perfused area.

**MAJOR PSYCHIATRIC DISORDERS AND BRAIN PERFUSION SINGLE PHOTON EMISSION COMPUTED TOMOGRAPHY**

**Attention deficit hyperactivity disorder**

Attention deficit hyperactivity disorder (ADHD) is one of the most prevalent disorders in child and adolescent psychiatry. Prevalence of ADHD in the general population is approximately 5% of school-age children. ADHD is characterized by a developmentally inappropriate poor attention span or age-inappropriate features of hyperactivity and impulsivity or both. To meet the Diagnostic and Statistical Manual of Mental Disorders-IV (DSM-IV) diagnostic criteria, the disorder should be present for at least 6 months, cause impairment in academic or social functioning, and occur before the age of 7 years. ADHD appears to be heterogeneous, with a variety of known etiologies such as head trauma, intrauterine exposure to toxins, and infections, but in the majority of cases no etiology can be determined. A neurobiological basis of ADHD resulting from the involvement of the fronto-striatal system has been proposed. Several studies [Table 1] analyzed the patterns of rCBF in ADHD, demonstrating decreases in brain perfusion, especially in the premotor cortex and the prefrontal cortex, and hypoperfusion of striatal and periventricular structures. Daniel et al. found that, 65% of children and adolescents with ADHD revealed decreased perfusion in the prefrontal cortex with intellectual stress, though only 25% had decreased prefrontal lobe activity at rest. There is a pattern of lateralization in prefrontal hypoperfusion from right to left with increase in age of patients as demonstrated by a study. Many researcher demonstrated temporal lobe dysfunction as significant in patients with ADHD. An association of temporal lobe hypoperfusion being more frequent than in the frontal cortex. An association of temporal lobe hypoperfusion with severity of
Obsessive-compulsive disorder
Obsessive-compulsive disorder is rare (5% of psychiatric patients), with a usually gradual onset in adolescence or early adult life and a slightly greater prevalence in females. Family history shows a high incidence in other members. Obsessions are imperative, distressing thoughts that persist despite the desire to resist them and may take various forms: Intellectual (phrases, rhymes, ideas, images), impulsive (killing, stabbing, performing abject acts), or inhibiting. Compulsions are acts that result from obsessions, such as checking rituals, repeated hand washing, and wiping objects. Brain SPECT findings in patients with OCD have been investigated by several authors [Table 2]. A study suggested involvement of prefrontal-striatal-thalamic and limbic circuitry in the pathophysiology of OCD. Hyperperfusion of the anterior portion of the cingulate gyrus; bilateral orbito-frontal regions; and in some patients, basal ganglia, before therapy has been described. These changes returned to normal after treatment with fluoxetine. In contrast, hypoperfusion of the frontal lobes, right caudate nucleus, and right thalamus has also been found. Patients with poor insight on their condition or with schizo-obssessive behavior probably will display hypoperfusion of the frontal lobes, whereas patients with adequate insight tend to display hyperperfusion of frontal lobes and cingulate gyrus. Impulsive issues are often from low activity in the prefrontal cortex and compulsive tendencies are usually due to high activity in the anterior cingulate gyrus. In our patients, we observed hypoperfusion of prefrontal, temporal and AC cortex in majority, probably due to our study group, which comprises chronic patients under long term treatment [Figure 2]. Anterior cingulate cortex seems to be an important structure in the pathogenesis of OCD symptoms and anterior cingulotomy is an approach for symptomatic improvement. The patients having increased activity in frontal and AC cortex also respond well to selective serotonin reuptake inhibitors. There is possible role of brain SPECT in tracking hereditary OCD or predicting future development of OCD in offspring.

receiving medication may show hyperfrontality and depending on positive or negative symptoms may show conflicting findings (hypo and hyperperfusion).

Patients with positive symptoms have demonstrated increased precuneus activity. Hypofrontality and temporal hypoperfusion related with negative symptoms and aggression in schizophrenia. Studies on treatment response evaluation demonstrated improvement of blood flow in frontal, temporal, basal ganglia region with increased activity in motor cortex. Involvement of inferior parietal cortex, cuneus and posterior temporal lobe are noted in chronic and progressive disease. Injection of perfusion agents at the time of visual or auditory hallucinations shows hyperperfusion of the primary visual or auditory cortex, respectively. Cognitive activation also significantly increases frontal activity in schizophrenia cases.

We have studied >50 patients of chronic schizophrenia and found significant hypoperfusion in prefrontal cortex mainly dorsolateral prefrontal cortex, and orbitofrontal cortex (OFC), temporal lobe, mainly temporopolar and superior temporal cortex, and inferior parietal lobule. There was also involvement of basal ganglia in 50% cases with occasional involvement of cerebellum, and sometimes global hypoperfusion [Figure 4] in severe cases.

**Anxiety and depression**

Anxiety and depression are extremely common public health problems in today’s world. The loss to our society from these illnesses is staggering: Individual pain, family strife, school and relationship failure, lost work productivity, and death. People actively seek out a cure for anxiety and depression, and are put on prescription medications that can harm them in other ways. Loss of interest or pleasure is the key symptom of depression. Other symptoms include feelings of hopelessness, worthlessness, and emotional pain; reduced energy and motivation; trouble sleeping;

![Figure 4](image3.png)

**Figure 4:** A 26-year-old male with disorganized schizophrenia was under treatment for last 1-year, showing global cortical hypoperfusion with relative increase in basal ganglia and cerebellar activity in technetium-99m-hexamethylpropyleneamineoxime brain perfusion single photon emission computed tomography-computed tomography images. (a) Transverse view, (b) sagittal view, (c) coronal view
decreased appetite and weight loss. Brain SPECT with perfusion agents in patients free of medication has shown hypoperfusion of the following areas: The prefrontal area and temporal lobes, cingulate gyrus, and left caudate nucleus. There is evidence of prefrontal, limbic, and paralimbic hypoperfusion in both unipolar and bipolar depression. The lateral frontal area involvement in acute depression in the elderly. Hypofrontality was shown to be associated with severe negative symptoms. In many occasions, both anxiety and depression coexist. Increased activity in the basal ganglia and frontal lobe may be seen in patients with anxiety. Severity of depression is inversely correlated with rCBF in left cingulate cortex, lentiform nucleus, and parahippocampal gyrus, and directly correlated with right posterolateral parietal cortex. Anxiety directly correlated with right anterolateral OFC, while cognitive performance correlated with right posteromedial OFC and left lentiform nucleus. Cognitive decline in postmenopausal women is also associated with hypofrontality. In major depressive disorders, sadness is related to decrease activity in dorsolateral prefrontal and dorsal cingulated cortex, with increased activity in ventromedial

**SPECT: Single photon emission computed tomography, ⁹⁹mTc-HMPAO: Technetium-99m-hexamethylpropyleneamineoxime, ⁹⁹mTc-ECD: Technetium-99m-ethylcysteinate dimer, rCBF: Regional cerebral blood flow, DLPFC: Dorsolateral prefrontal cortex, OFC: Orbito-frontal cortex, fMRI: Functional magnetic resonance imaging, MRS: Magnetic resonance spectroscopy, IMP: Iodomethyltyrosine, BPRS: Brief psychiatric rating scale, B/L: Bilateral
prefrontal and ventral cingulated cortex; whereas anxiety is associated with left AC cortex. Whole brain blood flow also correlated positively with anxiety. When recurrent depressions progressed to melancholies, involvement of left posterior parieto-temporal region is seen in addition to hypofrontality. Findings of brain SPECT in anxiety depression disorders from different studies are summarized in Table 4.

Substance abuse and addiction
Psychoactive substance abuse and dependence are disorders defined by patterns of maladaptive behavior related to the procurement and ingestion of substances of abuse (marijuana, hallucinogens, inhalants, cocaine, crack, heroin, stimulants, alcohol, and others). Short and long-term substance abuse affects blood flow and metabolism, which negatively affect the way our central nervous system works [Table 5]. Fortunately, some researchers report that the damage associated with chronic use of alcohol, nicotine, inhalants, and solvents is at least partially reversible with de-addiction treatment. Brain SPECT, has shown disseminated CBF defects in abusers of cocaine, crack, heroin and alcohol. [Figures 7 and 8].

Disappearance or improvement of the defects after a period of abstinence has been described, suggesting that arterial spasms may cause the defects. Some studies in cocaine abusers described abnormality in the OFC and superior temporal cortex, with evidence of minute differences between men and women. Patients with a history of inhalation of industrial solvents, such as glue, paint, and gasoline, have similar perfusion abnormalities.

Autism spectrum disorders
Autism spectrum disorders (ASD) are diagnosed today more than ever before. It has incidence rate of 2.5/10,000 births, males 1.5 times more commonly affected than females. This disorder is an early and severe development disorder, characterized by deficits in verbal and nonverbal languages, social skills, cognitive functioning and abnormal repetition of behavior (DSM-III R criteria). All children, teens, and adults with ASD are individuals and have unique brain patterns-one size does not fit all when it comes to ASD. Though SPECT studies are normal in many of the autism patients, it may show decreased temporal lobe perfusion. Up to 30% of autistic children eventually develop temporal lobe epilepsy. A study by Degirmenci et al. suggested the existence of regional brain perfusion alterations in frontal, temporal, and parietal cortex and in caudate nucleus in autistic children and in their first-degree family member.

SINGLE PHOTON EMISSION COMPUTED TOMOGRAPHY TO PERSONALISE TREATMENT IN PSYCHIATRIC DISORDERS

When brain SPECT scans detect the hyperfrontality pattern, it opens new avenues for intervention since this finding has been associated with predicting a positive treatment response to serotonergic medications in depression and OCD.
predicting a positive response to sleep deprivation\textsuperscript{86,87} and repetitive transcranial magnetic stimulation\textsuperscript{88} for depression, predicting treatment response to a cingulotomy in OCD,\textsuperscript{89} and help in distinguishing OCD from ADHD.\textsuperscript{90} Hypofrontality, that is, decreased perfusion or activity in the prefrontal cortex, is another important brain SPECT finding that is often helpful

| Table 4: Summary of important brain perfusion study findings in patients suffering from anxiety-depression disorder |
|---------------------------------------------------------------|
| **Author** | **Year** | **Study group** | **Imaging** | **Perfusion pattern (↓hypoperfusion, ↑hyperperfusion)** |
|----------------|--------|-------|-----------|---------------------------------|
| Kim et al. | 2008 | Depression in CKD | ⁹⁹mTc-HMPAO SPECT | Negatively correlated with rCBF in the right insula, posterior cingulate gyrus, and left superior temporal gyrus |
| Yao et al. | 2008 | Depression in postmenopausal women | ⁹⁹mTc-HMPAO SPECT | Positively correlated with rCBF in the left fusiform gyrus ↓Frontal CBF related to cognitive decline |
| Perico et al. | 2004 | Major depressive disorder | ⁹⁹mTc-HMPAO SPECT | Depression inversely correlated with rCBF in left cingulate, lentiform nucleus, and paraphippocampal gyrus, and directly correlated with right postero-lateral parietal cortex; anxiety directly correlated with right anterolateral orbito-frontal cortex, while cognitive performance correlated with right postero-medial orbito-frontal cortex and left lentiform nucleus |
| Carey et al. | 2004 | Anxiety disorder with citalopram | ⁹⁹mTc-HMPAO SPECT | Responders had deactivation in left precentral, right mid and inferior frontal, left prefrontal and right precuneus |
| Gillin et al. | 2001 | Sleep deprivation as antidepressant treatment | ⁹⁹mTc-HMPAO FPECT | Sleep deprivation normalizes hyperactive areas in orbital medial prefrontal cortex, and ventral anterior cingulate cortex |
| Brody et al. | 2001 | Major depressive disorder-symptom correlation | ⁹⁹mTc-HMPAO SPECT | Sadness ↓DLPFC and dorsal AC, and ↑VMPFC and ventral AC (2) psychomotor retardation ↓left prefrontal activity (3) anxiety ↓left AC activity (4) impaired episodic memory ↓left prefrontal and medial temporal (5) attention deficit ↓right prefrontal and parietal |
| Fernández-Argüelles et al. | 1998 | Recurrent depression | ⁹⁹mTc-HMPAO SPECT | Bilateral ↓B/L prefrontal and/or left posterior parietotemporal side melanholic had ↓left posterior parietotemporal |
| Lucey et al. | 1997 | Anxiety, panic, depression, PTSD | ⁹⁹mTc-HMPAO SPECT | Whole brain blood flow correlated positively with anxiety, depression/PTSD correlated negatively with B/L caudate rCBF |
| Philpot et al. | 1993 | Late life depression | ⁹⁹mTc-HMPAO SPECT | Cortico-cerebellar ratios of tracer uptake in B/L parietal, left temporal and left occipital |

**SPECT:** Single photon emission computed tomography. ⁹⁹mTc-HMPAO: Technetium-99m-hexamethyl propylene amine oxime, ⁹⁹mTc-ECD: Technetium-99m-ethylcysteinate dimer, rCBF: Regional cerebral blood flow, DLPCF: Dorsolateral prefrontal cortex, VMPFC: Ventromedial prefrontal cortex, AC: Anterior cingulated, B/L: Bilateral, PTSD: Posttraumatic stress disorder, CKD: Chronic kidney disease, CBF: Cerebral blood flow

predicting a positive response to sleep deprivation\textsuperscript{86,87} and repetitive transcranial magnetic stimulation\textsuperscript{88} for depression, predicting treatment response to a cingulotomy in OCD,\textsuperscript{89} and help in distinguishing OCD from ADHD.\textsuperscript{90} Hypofrontality, that is, decreased perfusion or activity in the prefrontal cortex, is another important brain SPECT finding that is often helpful.

| Table 5: Summary of important brain perfusion study findings in patients suffering from substance abuse disorders |
|---------------------------------------------------------------|
| **Author** | **Year** | **Study group** | **Imaging** | **Perfusion pattern (↓hypoperfusion, ↑hyperperfusion)** |
|----------------|--------|-------|-----------|---------------------------------|
| Our findings | - | Multiple drug abuse | ⁹⁹mTc-HMPAO SPECT | Global hypoperfusion with diffuse involvement of cortical and subcortical structures Reversible generalized cerebral dysfunction in AIPD |
| Jordaen et al. | 2012, 2010 | Alcohol-induced psychotic disorder | SPECT | ↓Frontal, temporal, basal ganglia, occipital inferior region, parietal superior |
| Adinoff et al. | 2012 | Cocaine addicted | SPECT | Hypoperfusion areas in left insula, and left superior temporal cortex ↑Frontal activity (4) impaired episodic memory ↓left prefrontal and medial temporal (5) attention deficit ↓left prefrontal and parietal |
| Nehlig et al. | 2010 | Sleep deprivation as antidepressant treatment | ⁹⁹mTc-HMPAO SPECT | ↓Frontal, temporal, basal ganglia, occipital inferior region, parietal superior |
| Chung et al. | 2009 | Alcohol-related dementia | ⁹⁹mTc-ECD | Global brain perfusion, more significant in the frontal (OFC), occipital and temporal lobes |
| Pach et al. | 2007 | Alcohol dependence | ⁹⁹mTc-ECD | Global brain perfusion, more significant in the frontal (OFC), occipital and temporal lobes |
| Botelho et al. | 2006 | Cocaine – sex difference | ⁹⁹mTc-HMPAO SPECT | ↑Frontal, temporal, basal ganglia, occipital inferior region, parietal superior |
| Adinoff et al. | 2006 | Heroin abusers | ⁹⁹mTc-HMPAO SPECT | ↑Frontal, temporal, basal ganglia, occipital inferior region, parietal superior |
| Demir et al. | 2002 | Alcoholism-early onset | ⁹⁹mTc-HMPAO SPECT | Early onset ↓left superior frontal region while the late onset ↓B/L superior frontal regions |
| Gottschalk et al. | 2002 | Combined alcohol and cocaine | ⁹⁹mTc-ECD | ↑Occipital and temporal cortex or cerebellum and ↑more likely in frontal and parietal cortex |
| Kucuk et al. | 2000 | Long term inhalant use | ⁹⁹mTc-HMPAO SPECT | Brain SPECT showed non-homogeneous uptake and hypoperfusion areas |
| Earnst et al. | 2000 | Abstinent cocaine abuser | ⁹⁹mTc-HMPAO SPECT | ↑Frontal white matter and in the globus pallidus, and ↑putamen and temporal cortex |
| Gansler et al. | 2000 | Abstinent alcoholics | ⁹⁹mTc-HMPAO SPECT | Frontal brain abnormalities in alcoholics may subside with extended abstinence |

**SPECT:** Single photon emission computed tomography. ⁹⁹mTc-HMPAO: Technetium-99m-exametazime-hexamethyl propyleneamineoxime, ⁹⁹mTc-ECD: Technetium-99m-ethylcysteinate dimer, rCBF: Regional cerebral blood flow, DLPCF: Dorsolateral prefrontal cortex, OFC: Orbito-frontal cortex, AIPD: Alcohol induced psychotic disorder, DLPCF: Dorsolateral prefrontal cortex, B/L: Bilateral

predicting a positive response to sleep deprivation\textsuperscript{86,87} and repetitive transcranial magnetic stimulation\textsuperscript{88} for depression, predicting treatment response to a cingulotomy in OCD,\textsuperscript{89} and help in distinguishing OCD from ADHD.\textsuperscript{90} Hypofrontality, that is, decreased perfusion or activity in the prefrontal cortex, is another important brain SPECT finding that is often helpful.
in understanding and targeting treatment in individual patients. Hypofrontality is associated with a negative response to serotonergic medication in depression\(^\text{[81]}\) and clozapine in schizophrenia\(^\text{[82]}\) as well as with predicting relapse in alcoholics,\(^\text{[93]}\) improved response to acetylcholine-esterase inhibitors for memory and behavior in AD,\(^\text{[94,95]}\) predicting a poor response to ketamine in fibromyalgia patients\(^\text{[96]}\) and improved response to stimulants in patients with ADHD symptoms during a concentration challenge.\(^\text{[97]}\) Hypofrontality is also associated with antisocial symptoms, impulsive behaviors, and murder\(^\text{[98]}\) as well as with completed suicide, which is often an impulsive act.\(^\text{[99]}\) When hypofrontality is present in depressed patients, it is important to be vigilant in their care, as well as involve family support, as they may be less likely to respond to typical antidepressant medications and they may not have the cognitive resources to follow through with recommendations.\(^\text{[100]}\) When abnormalities in the temporal lobes are seen (either hypo or hyperperfusion) and mood instability or temper problems are present, anticonvulsants provide a rational treatment option.\(^\text{[101]}\) If there are memory or learning issues (and low temporal lobe perfusion), acetylcholine-esterase inhibitors may be helpful,\(^\text{[102]}\) always taking into consideration the clinical picture.

**CONCLUSIONS**

Brain perfusion SPECT is a valuable tool in management of psychiatric disorders. It has a role in the diagnosis, therapeutic management, and follow-up of these patients. In addition, brain SPECT is a useful tool for research, because it is widely available and provides noninvasive *in vivo* assessment of human brain function. We can use this tool in psychiatric practice to evaluate the involvement of brain regions in a patient for a particular clinical condition, can individualize the treatment on basis of brain SPECT findings, can monitor the treatment response and modify the treatment, if necessary. There are a number of important areas where brain SPECT has the potential to provide relevant information to help personalize treatment to patients’ specific brain system pathophysiology rather than rely solely on general diagnostic and/or therapeutic categories. Brain SPECT should always be evaluated in conjunction with clinical assessment since it adds value to routine clinical assessment.
