INSTANTON FLOER HOMOLOGY, SUTURES, AND EULER CHARACTERISTICS

ZHENKUN LI AND FAN YE

Abstract. This is a companion paper to an earlier work of the authors. In this paper, we provide an axiomatic definition of Floer homology for balanced sutured manifolds and prove that the graded Euler characteristic $\chi_{gr}$ of this homology is fully determined by the axioms we proposed. As a result, we conclude that $\chi_{gr}(SH(M, \gamma)) = \chi_{gr}(SFH(M, \gamma))$ for any balanced sutured manifold $(M, \gamma)$. In particular, for any link $L$ in $S^3$, the Euler characteristic $\chi_{gr}(KH(S^3, L))$ recovers the multi-variable Alexander polynomial of $L$, which generalizes the knot case. Combined with the authors’ earlier work, we provide more examples of $(1, 1)$-knots in lens spaces whose $KH$ and $HFK$ have the same dimension. Moreover, for a rationally null-homologous knot in a closed oriented 3-manifold $Y$, we construct canonical $\mathbb{Z}_2$-gradings on $KH(Y, K)$, the decomposition of $I(Y)$ discussed in the previous paper, and the minus version of instanton knot homology $KH^-(Y, K)$ introduced by the first author.

1. Introduction

Sutured manifold theory was introduced by Gabai [Gab83], and Floer theory was introduced by Floer [Flo88]. They are both powerful tools in the study of 3-manifolds and knots. The first combination of these theories, called sutured Floer homology, was introduced by Juhász [Juh06] based on Heegaard Floer theory, with some pioneering work done by Ghiggini [Ghi08] and Ni [Ni07]. Later, Kronheimer and Mrowka made analogous constructions in monopole (Seiberg-Witten) theory and instanton (Donaldson-Floer) theory [KM10b]. Different versions of Floer theories have different merits. For example, Heegaard Floer theory is more computable, while instanton theory is closely related to representation varieties of fundamental groups. Hence it is important to understand the relationship between different versions of Floer theories. In this line, Lekili [Lek13] and Baldwin and Sivek [BS20b] proved that sutured (Heegaard) Floer homology is isomorphic to sutured monopole homology, though the relation to sutured instanton homology is still open.

Conjecture 1.1 ([KM10b, Conjecture 7.24]). For a balanced sutured manifold \((M, \gamma)\), we have

\[
SHI(M, \gamma) \cong SFH(M, \gamma) \otimes \mathbb{C}.
\]

In particular, for a knot \(K\) in a closed oriented 3-manifold \(Y\), there are isomorphisms

\[
I^\partial(Y) \cong \widehat{HF}(Y) \otimes \mathbb{C} \quad \text{and} \quad KHI(Y, K) \cong \widehat{HFK}(Y, K) \otimes \mathbb{C}.
\]

Here \(SHI\) is sutured instanton homology [KM10b], \(SFH\) is sutured (Heegaard) Floer homology [Juh06], \(I^\partial\) is framed instanton Floer homology [KM11a], \(\widehat{HF}\) is the hat version of Heegaard Floer homology [OS04d], \(KHI\) is instanton knot homology [KM10b], and \(\widehat{HFK}\) is the hat version of knot Floer homology [OS04b, Ras03].

In this paper, instead of studying the full homologies, we study their graded Euler characteristics and obtain the following theorem.

Theorem 1.2. Suppose \((M, \gamma)\) is a balanced sutured manifold and \(S_1, \ldots, S_n\) are properly embedded admissible surfaces (c.f. Definition 2.21) generating \(H_2(M, \partial M)\)/\(\text{Tors}\). Then there exist \(\mathbb{Z}^n\)-gradings on \(SHI(M, \gamma)\) and \(SFH(M, \gamma)\) induced by these surfaces, respectively. Equivalently, we have

\[
SHI(M, \gamma) = \bigoplus_{(i_1, \ldots, i_n) \in \mathbb{Z}^n} SHI(M, \gamma, (S_1, \ldots, S_n), (i_1, \ldots, i_n))
\]

and a similar result holds for \(SFH(M, \gamma)\). Moreover, there exist relative \(\mathbb{Z}_2\)-gradings on \(SHI(M, \gamma)\) and \(SFH(M, \gamma)\), respecting the decompositions. Define

\[
\chi_{gr}(SHI(M, \gamma)) := \sum_{(i_1, \ldots, i_n) \in \mathbb{Z}^n} \chi(SHI(M, \gamma, (S_1, \ldots, S_n), (i_1, \ldots, i_n)) \cdot t_1^{i_1} \cdots t_n^{i_n},
\]

and define \(\chi_{gr}(SFH(M, \gamma))\) similarly. Then we have

\[
\chi_{gr}(SHI(M, \gamma)) \sim \chi_{gr}(SFH(M, \gamma)),
\]

where \(\sim\) means two polynomials equal up to multiplication by \(\pm t_1^{j_1} \cdots t_n^{j_n}\) for some \((j_1, \ldots, j_n) \in \mathbb{Z}^n\).

Remark 1.3. Suppose that \(t_1, \ldots, t_n\) represent generators of

\[
H = H_1(M; \mathbb{Z})/\text{Tors} \cong H_2(M, \partial M; \mathbb{Z})/\text{Tors}.
\]

Then \(\sim\) means the equality holds for elements in \(\mathbb{Z}[H]/\pm H\).
The graded Euler characteristic \( \chi_{gr}(SFH(M, \gamma)) \) was studied by Friedl, Juhász, and Rasmussen [FJR09]. Applying their results, we can relate the graded Euler characteristics of links with classical invariants obtained from fundamental groups.

Consider a finitely generated group \( \pi = \langle x_1, \ldots, x_n | r_1, \ldots, r_k \rangle \). Let \( H = H_1(\pi)/\text{Tors} \) be the abelianization of \( \pi \) modulo torsions. For a generator \( x_i \) and a word \( w \), let \( \partial w/\partial x_i \) be the Fox derivative of \( w \) with respect to \( x_i \). Equivalently, it satisfies the following conditions.

1. For any word \( w = u \cdot v \), we have \( \frac{\partial w}{\partial x_i} = \frac{\partial u}{\partial x_i} + \frac{\partial v}{\partial x_i} \).
2. \( \frac{\partial w}{\partial x_i} = 1 \) and \( \frac{\partial w}{\partial x_i} = 0 \) for any \( j \neq i \).

Consider \( A = \{ \partial r_j/\partial x_i \}_{i,j} \) as a matrix with entries in \( \mathbb{Z}[H] \) by the projection map \( \mathbb{Z}[\pi] \to \mathbb{Z}[H] \). Let \( E(\pi) \) be the ideal generated by the minor determinants of \( A \) of order \( (n - 1) \). Since \( \mathbb{Z}[H] \) is a unique factorization domain, one can consider the greatest common divisor of the elements of \( E(\pi) \), which is well-defined up to multiplication by a unit in \( \pm H \). This is denoted by \( \Delta(\pi) \) and called the **Alexander polynomial** of \( \pi \) (c.f. [Tur02]). For a 3-manifold \( M \), the Alexander polynomial of \( M \) is defined by \( \Delta(M) := \Delta(\pi(M)) \). For an \( n \)-component link \( L \) in \( S^3 \), we write \( t_1, \ldots, t_n \) for homology classes of meridians of components of \( L \) and define \( \Delta_L(t_1, \ldots, t_n) := \Delta(S^3/\text{int} \, N(L)) \) as the **multi-variable Alexander polynomial** of \( L \). If \( n = 1 \) and \( L = K \) is a knot, we can fix the ambiguity of \( \pm H \) by assuming \( \Delta_K(t_1) = \Delta_K(t_1^{-1}) \) and \( \Delta_K(1) = 1 \). In this case, we call it the **symmetrized Alexander polynomial** of \( K \).

**Theorem 1.4.** Suppose \( M \) is a compact manifold whose boundary consists of tori \( T_1, \ldots, T_n \) with \( b_1(M) \geq 2 \). Suppose

\[
\gamma = \bigcup_{j=1}^n m_j \cup (-m_j)
\]

consists of two simple closed curves with opposite orientations on each torus. Suppose \( H = H_1(M; \mathbb{Z})/\text{Tors} \) and \( [m_1], \ldots, [m_n] \) are homology classes. Then we have

\[
(1.2) \quad \chi_{gr}(SHI(M, \gamma)) = \Delta(M) \cdot \prod_{j=1}^n ([m_j] - 1) \in \mathbb{Z}[H]/\pm H.
\]

In particular, suppose \( L \subset S^3 \) is an \( n \)-component link with \( n \geq 2 \). Define

\[
(1.3) \quad KHI(L) := \text{SHI}(S^3/\text{int} \, N(L), \bigcup_{j=1}^n m_j \cup (-m_j)),
\]

where \( m_1, \ldots, m_n \) are meridians of components of \( L \). Let \( (i_1, \ldots, i_n) \) denote the \( \mathbb{Z}^n \)-grading on \( KHI(L) \) induced by Seifert surfaces of components of \( L \). Then we have

\[
\chi_{gr}(KHI(L)) := \sum_{(i_1, \ldots, i_n) \in \mathbb{Z}^n} \chi(KHI(L, (S_1, \ldots, S_n), (i_1, \ldots, i_n))) t_1^{i_1} \cdots t_n^{i_n} \sim \Delta_L(t_1, \ldots, t_n) \prod_{j=1}^n (t_j - 1),
\]

where \( \sim \) means the equality holds for elements in \( \mathbb{Z}[H]/\pm H \).

**Remark 1.5.** A similar result to Theorem 1.4 has been proved for link Floer homology in Heegaard Floer theory by Ozsváth and Szabó [OS08]. For instanton theory, the case of single-variable Alexander polynomial for links in \( S^3 \) was understood by Kronheimer and Mrowka [KM10a] and independently by Lim [Lim09], while the case of the multi-variable polynomial was unknown before.

For knots, the corresponding corollary is the following.
Theorem 1.6. Suppose \( K \) is a knot in a closed oriented 3-manifold \( Y \). Suppose \( Y(K) := Y\setminus \text{int}N(K) \) is the knot complement and \( b_1(Y(K)) = 1 \). Let \( [m] \in H = H_1(Y(K);\mathbb{Z})/\text{Tors} \cong \mathbb{Z}/t \) be the homology class of the meridian of \( K \). Define \( KHI(Y, K) \) similarly to \( KHI(L) \) as in (1.3). Then we have
\[
\chi_{gr}(KHI(Y, K)) = \Delta(Y(K)) \cdot \frac{[m] - 1}{t - 1} \in \mathbb{Z}[H]/\pm H.
\]

Remark 1.7. Analogous results of Theorem 1.6 in Heegaard Floer theory can be found in [RR17, Proposition 2.1] and [Ras07, Proposition 3.1]. Also, Theorem 1.6 is a generalization of work of Kronheimer and Mrowka [KM10b, KLT10a, KLT10b, KLT10c, KLT11, KLT12], and the relation between SHM and \( \text{SFH} \) by work of Colin, Ghiggini, and Honda [CGH11] and [BLSY21, KLT10a, KLT10b, KLT10c, KLT11, KLT12], and the relation between \( \text{SHI} \) and \( \text{SFH} \) by work of Lekili [Lek13] or independently Baldwin and Sivek [BS20b].

An application of Theorem 1.6 is to compute the instanton knot homology of some special families of knots. In [LY20], the authors proved the following.

Theorem 1.10 ([LY20, Theorem 1.4]). Suppose \( K \subset Y \) is a \((1,1)\)-knot in a lens space (including \( S^3 \)). Then we have
\[
\dim_{\mathbb{C}} KHI(Y,K) \leq \dim_{\mathbb{R}} \widehat{HF}(Y,K).
\]

Obviously, a lower bound of \( \dim_{\mathbb{C}} KHI(Y,K) \) can be obtained from \( \chi_{gr}(KHI(Y,K)) \). If this lower bound coincides with the upper bound from Theorem 1.10, then we figure out the precise dimension of \( KHI(Y,K) \). This trick applies to \((1,1)\)-knots in \( S^3 \), which are either homologically thin knots or Heegaard Floer L-space knots. In [LY20], the authors worked with knots in \( S^3 \) because prior to the current paper, the graded Euler characteristic of instanton knot homology was only understood in that case. On the other hand, in [Ye21], the second author discovered a family of \((1,1)\)-knots in general lens spaces whose \( \dim_{\mathbb{R}} \widehat{HF}(Y,K) \) is determined by \( \chi(\widehat{HF}(Y,K)) \). Hence, with Theorem 1.6 and results in [Ye21], we conclude the following.

Corollary 1.11. Suppose \( Y \) is a lens space, and \( K \subset Y \) is a \((1,1)\)-knot such that

1. either \( K \) admits an L-space surgery (c.f. [RR17, Lemma 3.2] and [GLV18, Theorem 2.2]), or
2. \( K \) is a constrained knot (c.f. [Ye21, Section 4]).
(2) $H_1(Y(K); \mathbb{Z}) \cong \mathbb{Z}$, where $Y(K)$ is the knot complement of $K$.

Then, we have
\[
\dim \mathbb{C} \text{KHI}(Y, K) = \dim \mathbb{Z} \text{HF}(Y, K).
\]

Remark 1.12. Greene, Lewallen, and Vafaee [GLV18] provided a clear criterion to check if a $(1, 1)$-knot admits an L-space surgery.

Remark 1.13. The condition $H_1(Y(K); \mathbb{Z}) \cong \mathbb{Z}$ is necessary since terms related to Euler characteristics of torsion spin$^c$ structures may cancel out when we consider the map between group rings induced by the projection $H_1(Y(K); \mathbb{Z}) \rightarrow H_1(Y(K); \mathbb{Z})/\text{Tors}$. In a subsequent paper [LY21], we introduced an enhanced Euler characteristic of $SHI$ to deal with the torsion part of $H_1(Y(K); \mathbb{Z})$ and remove the second condition in Corollary 1.11.

Now, we explain the rough idea to prove Theorem 1.2. First, let us consider the case of a closed oriented 3-manifold $Y$. The Euler characteristic of the framed instanton Floer homology, $\chi(I^7(Y))$, was understood by Scaduto [Sca15, Section 10]. The strategy is to carry out an induction on the order of $H_1(Y; \mathbb{Z})$ using exact triangles. The grading behavior of $\chi(I^7(Y))$ under a surgery exact triangle was fully described as in [KM07] Section 42.3 and it is known that $\chi(I^7(Y')) = 1$ for any integral homology sphere $Y'$. Hence we can prove $\chi(I^7(Y)) = |H_1(Y; \mathbb{Z})|$ inductively.

However, the above argument requires more care when we take into account gradings associated to surfaces inside 3-manifolds. Suppose $R \subset Y$ is a closed homologically essential surface. Then $R$ induces a $\mathbb{Z}$-grading on $I^7(Y)$ by considering the generalized eigenspaces of the linear action $\mu(R)$ on $I^7(Y)$ (c.f. [KM10b] Section 7). When trying to understand the graded Euler characteristic in this case, the previous strategy does not apply directly. The reason is that, the surgery curves inducing the exact triangles may have nontrivial algebraic intersections with the surface $R$, so the maps in surgery exact triangles may not preserve the grading associated to $R$. We are faced with the same problem when proving Theorem 1.2.

Our strategy is the following. Suppose $(M, \gamma)$ is a balanced sutured manifold and suppose $S_1, \ldots, S_n$ are properly embedded surfaces in $M$. Then $S_1, \ldots, S_n$ induce a $\mathbb{Z}^n$-grading on $SHI(M, \gamma)$. After attaching product 1-handles along $\partial M$, we can find a framed link in the interior of the resulting manifold such that the link is disjoint from all the surfaces. Moreover, surgeries along the link with all slopes chosen in $\{0, 1\}$ produce only handlebodies. Since the surgery link is disjoint from the surfaces $S_1, \ldots, S_n$ that induce the $\mathbb{Z}^n$-grading, the maps in surgery exact triangles preserve the grading. Hence, it suffices to understand the case of sutured handlebodies. In this case, we can further use bypass exact triangles to reduce any sutured handlebodies to product sutured manifolds. It is known that the Floer homology of any product sutured manifold is one-dimensional. Since the behavior of Euler characteristics under bypass exact triangles and surgery exact triangles are the same for both instanton theory and Heegaard Floer theory, we finally conclude that these two versions of Floer theories must have the same graded Euler characteristic.

In the above argument, it is not necessary to treat instanton theory and Heegaard Floer theory separately. Instead, we only use some formal properties that are shared by both theories, and hence we can deal with them at the same time. This observation can be made more general. In Kronheimer and Mrowka’s definition of sutured (monopole or instanton) Floer homology, they constructed a closed 3-manifold, called a closure, out of a balanced sutured manifold in a topological manner, and defined the Floer homology for a balanced sutured manifold to be some direct summands of the Floer homology of its closure. Then they used the formal properties of monopole theory and instanton theory to show that the construction is independent of the choice of the closures. In the
following series of work [BS15, BS16a, BS16b, Li19, GL19], most arguments were also carried out based on topological constructions and hence only depend on the formal properties of Floer theories.

In this paper, we summarize the necessary properties of Floer theory that are used to build a sutured homology for balanced sutured manifolds. In Subsection 2.1, we state three axioms for $(3+1)$-TQFTs (functors from cobordism categories to categories of vector spaces) called:

- (A1) the adjunction inequality axiom;
- (A2) the surgery exact triangle axiom;
- (A3) the canonical $\mathbb{Z}/2$ grading axiom.

A $(3+1)$-TQFT satisfying these axioms is called a Floer-type theory. For any Floer-type theory $H$ and any balanced sutured manifold $(M,\gamma)$, we construct a vector space $SH(M,\gamma)$, called the formal sutured homology of $(M,\gamma)$, over a suitable coefficient ring. More precisely, we have the following theorem.

**Theorem 1.14.** Suppose $H$ is a $(3+1)$-TQFT and suppose $(M,\gamma)$ is a balanced sutured manifold. If $H$ satisfies Axioms (A1) and (A2), then there is a vector space $SH(M,\gamma)$ well-defined up to multiplication by a unit in the base field $\mathbb{F}$. Suppose $S_1,\ldots,S_n$ are properly embedded admissible surfaces inside $(M,\gamma)$. Then there exists a $\mathbb{Z}$-grading on $SH(M,\gamma)$ induced by these surfaces, i.e.

$$SH(M,\gamma) = \bigoplus_{(i_1,\ldots,i_n)\in\mathbb{Z}^n} SH(M,\gamma,(S_1,\ldots,S_n),(i_1,\ldots,i_n)).$$

Furthermore, if $H$ satisfies Axiom (A3), then there exists a relative $\mathbb{Z}/2$-grading $SH(M,\gamma)$, respecting the decomposition in (1.4). Moreover, the graded Euler characteristic $\chi_{gr}(SH(M,\gamma))$, defined similarly to (1.1) and determined up to multiplication by a unit in $\pm H_1(M)/\text{Tors}$, is independent of the choice of the Floer-type theory.

**Remark 1.15.** A priori, the definition of formal sutured homology depends on a large and fixed integer $g$, which is the genus of the closure; see the Convention after Definition 2.17.

**Remark 1.16.** The construction of $SH$ is essentially due to the work of Kronheimer and Mrowka [KM10]. Note that instanton theory, monopole theory and Heegaard Floer theory all satisfy Axioms (A1), (A2), and (A3) with coefficients $\mathbb{C}$, $\mathbb{F}_2$ and $\mathbb{F}_2$, respectively, up to mild modifications (c.f. Subsection 2.1). Moreover, Axioms (A1), (A2), and (A3) are not limited by the scope of gauge-theoretic theories mentioned above and may hold for other more general $(3+1)$-TQFTs.

There is one further step to prove Theorem 1.2 from Theorem 1.14. For Heegaard Floer theory, the construction coming from Theorem 1.14 is different from the original version of sutured (Heegaard) Floer homology defined by Juhász [Juh06]. It has been shown by Lekili [Lek13] and Baldwin and Sivek [BS20a] that these two constructions coincide with each other. Although not shown explicitly, their proofs also imply that the isomorphism between these two constructions respects gradings.

Based on their work, we show the following proposition.

**Proposition 1.17.** Suppose $(M,\gamma)$ is a balanced sutured manifold and suppose $H = H_1(M)/\text{Tors}$. Suppose $SHF$ is the sutured homology for balanced sutured manifolds constructed in Theorem 1.14 for Heegaard Floer theory. Then we have

$$\chi_{gr}(SHF(M,\gamma)) = \chi_{gr}(SFH(M,\gamma)) \in \mathbb{Z}[H]/\pm H.$$

Other than Theorem 1.14, there are more results that can be derived from axioms and formal properties of the formal sutured homology $SH$. Since the proofs in [BLY20, LY20] are only based on those formal properties, all results can be applied to $SH$ without essential changes. In particular, the following theorem is just the main theorem of [BLY20], replacing $SHI$ by $SH$. 
Then there is a decomposition up to isomorphism
\[ \text{dim}_\mathbb{F} \text{SH}(M, \gamma) \leq |\mathcal{G}(\mathcal{H})|. \]

Combining the lower bound from Theorem 1.14 and the upper bound from Theorem 1.18, we obtain the following corollary.

**Corollary 1.19.** Formal sutured homology $\text{SH}$ is independent of the choice of the $(3 + 1)$-TQFT satisfying Axioms $(A1)$, $(A2)$ and $(A3)$ in the following cases (c.f. Definition 5.1):

- All alternating knots in $S^3$ (c.f. [OS03]),
- All $(1, 1)$-knots satisfying the assumption of Corollary 1.11 including all torus knots in $S^3$,
- All strong $L$-spaces (including double branched covers of non-split alternating links) and knots induced by strong Heegaard diagrams (c.f. [Gre13, GL16]).

Next, we discuss the $\mathbb{Z}_2$-grading on $\text{SH}(M, \gamma)$. Following [KM10b], to construct $\text{SH}(M, \gamma)$, we first construct a closure $Y$ from $(M, \gamma)$. From a fixed balanced sutured manifold $(M, \gamma)$, we can construct infinitely many different closures (with the same genus), and the Floer homology of each closure has its own (absolute) $\mathbb{Z}_2$-grading. Although we can construct isomorphisms between the Floer homology of different closures, the maps do not necessarily respect the $\mathbb{Z}_2$-gradings. See [KM10a] Section 2.6 for a concrete example. Thus, we cannot obtain a canonical $\mathbb{Z}_2$-grading on $\text{SH}(M, \gamma)$ and the Euler characteristic can only be defined up to a sign (since we do know the maps between closures are homogenous with respect to the $\mathbb{Z}_2$-gradings).

However, if we focus on balanced sutured manifolds whose underlying 3-manifolds are knot complements of null-homologous knots and whose sutures have two components, it is possible to obtain a canonical $\mathbb{Z}_2$-grading. The idea is to compare closures of a general knot with closures of the unknot in $S^3$ and then fix the relative $\mathbb{Z}_2$-grading. When the suture on the boundary of the knot complement consists of two meridians, we recover the canonical $\mathbb{Z}_2$-grading on $KHI(Y, K)$ already known by Floer [Flo90a] and Kronheimer and Mrowka [KM10a]. When the suture on the boundary of knot complement consists of two curves of slope $-n$, this canonical $\mathbb{Z}_2$-grading is also carried over to the following decomposition of $I^q(Y)$ introduced by the authors.

**Theorem 1.20 ([LY20 Theorem 1.10]).** Suppose $Y$ is a closed 3-manifold, and $K \subset Y$ is a null-homologous knot. Suppose $\hat{Y}$ is obtained from $Y$ by performing the $q/p$ surgery along $K$ with $q > 0$. Then there is a decomposition up to isomorphism
\[ I^q(\hat{Y}) \cong \bigoplus_{i=0}^{q-1} I^q(\hat{Y}, i), \]
associated to the knot $K$ and the slope $q/p$.

**Proposition 1.21.** Under the hypothesis and the statement of Theorem 1.20, there is a well-defined $\mathbb{Z}_2$-grading on $I^q(\hat{Y}, i)$. Moreover, for $i = 0, \ldots, q - 1$, we have
\[ \chi(I^q(\hat{Y}, i)) = \chi(I^q(Y)). \]

**Corollary 1.22.** Suppose $K$ is a knot in an integral homology sphere $Y$. Suppose further that $r = q/p$ is a rational number with $q > 0$. Then, the 3-manifold $Y_r(K)$ is an instanton $L$-space (i.e., $\dim_\mathbb{C} I^q(Y) = |H_1(Y; \mathbb{Z})|$) if and only if for $i = 0, \ldots, q - 1$, we have
\[ I^q(Y_r(K), i) \cong \mathbb{C}. \]
Proof. If for $i = 0, \ldots, q - 1$, we have $I^i(Y_r(K), i) \cong \mathbb{C}$, then it follows directly from Theorem 1.20 that $Y_r(K)$ is an instanton L-space.

Now suppose $Y_r(K)$ is an instanton L-space. Applying Proposition 1.21 to $Y$, we have

\[
\dim_{\mathbb{C}} I^2(Y_r(K)) \geq |\chi(I^2(Y_r(K)))| = \left| \sum_{i=0}^{q-1} \chi(I^2(Y_r(K), i)) \right| = \left| \sum_{i=0}^{q-1} \chi(I^2(Y)) \right| = q.
\]

By assumption, $Y_r(K)$ is an instanton L-space, i.e.,

\[
\dim_{\mathbb{C}} I^2(Y_r(K)) = |H_1(Y_r(K))| = q.
\]

Hence the inequality in (1.5) is sharp, which implies $\dim_{\mathbb{C}} I^2(Y_r(K), i) = 1$. \hfill $\square$

The techniques to prove Proposition 1.21 can also be applied to study the minus version of instanton knot homology $KHI^-$, which was introduced by the first author in [Li19, Section 5].

Proposition 1.23. Suppose $K \subset S^3$ is a knot and $\Delta_K(t)$ is the symmetrized Alexander polynomial of $K$. Then there is a canonical $\mathbb{Z}_2$-grading on $KHI^-(\mathbb{S}^3, K)$. Furthermore, we have

\[
\sum_{i \in \mathbb{Z}} \chi(KHI^-(\mathbb{S}^3, K), i) \cdot t^i = -\Delta_K(t) \cdot t^{-1}.
\]

Remark 1.24. The analogous result of Proposition 1.23 in Heegaard Floer theory had been known by the work of Ozsváth and Szabó [OS04b].

Conventions. If it is not mentioned, homology groups and cohomology groups are with $\mathbb{Z}$ coefficients, i.e., we write $H_*(Y)$ for $H_*(Y; \mathbb{Z})$. A general field is denoted by $\mathbb{F}$, and the field with two elements is denoted by $\mathbb{F}_2$.

If it is not mentioned, all manifolds are smooth and oriented. Moreover, all manifolds are connected unless we indicate disconnected manifolds are also considered. This usually happens when discussing cobordism maps from a $(3 + 1)$-TQFT.

Suppose $M$ is an oriented manifold. Let $-M$ denote the same manifold with the reverse orientation, called the mirror manifold of $M$. If it is not mentioned, we do not consider orientations of knots.

Suppose $K$ is a knot in a 3-manifold $M$. Then $(-M, K)$ is the mirror knot in the mirror manifold.

For a manifold $M$, let $\text{int}(M)$ denote its interior. For a submanifold $A$ in a manifold $Y$, let $\text{int}(A)$ denote the tubular neighborhood. The knot complement of $K$ in $Y$ is denoted by $Y(K) = Y \setminus \text{int}(N(K))$.

For a simple closed curve on a surface, we do not distinguish between its homology class and itself. The algebraic intersection number of two curves $\alpha$ and $\beta$ on a surface is denoted by $\alpha \cdot \beta$, while the number of intersection points between $\alpha$ and $\beta$ is denoted by $|\alpha \cap \beta|$. A basis $(m, l)$ of $H_1(T^2; \mathbb{Z})$ satisfies $m \cdot l = -1$. The surgery means the Dehn surgery and the slope $q/p$ in the basis $(m, l)$ corresponds to the curve $qm + pl$.

A knot $K \subset Y$ is called null-homologous if it represents the trivial homology class in $H_1(Y; \mathbb{Z})$, while it is called rationally null-homologous if it represents the trivial homology class in $H_1(Y; \mathbb{Q})$. We write $\mathbb{Z}_n$ for $\mathbb{Z}/n\mathbb{Z}$.

An argument holds for large enough or sufficiently large $n$ if there exists a fixed $N \in \mathbb{Z}$ so that the argument holds for any integer $n > N$.

Organization. The paper is organized as follows. In Section 2 we introduce three axioms to define formal sutured homology for balanced sutured manifolds and prove the first part of Theorem 1.14. Moreover, we state many useful properties for the proof of the second part of Theorem 1.14.
Section 3, we discuss the modification of Heegaard Floer theory to make it suitable to formal sutured homology and prove Proposition 1.17. In Section 4, we prove the second part of Theorem 1.14. In Section 5, we construct a canonical $\mathbb{Z}_2$-grading for balanced sutured manifolds obtained from knots in closed 3-manifolds and prove Proposition 1.21 and Proposition 1.23.

Acknowledgement. The authors thank Ian Zemke for pointing out a mistake in the previous statement of Corollary 3.21 and helping with the new proof of Floer’s excision theorem for Heegaard Floer theory in Subsection 3.3. The authors also thank John A. Baldwin and Yi Xie for valuable discussions and anonymous referees for the helpful comments. The first author thanks Ciprian Manolescu and Joshua Wang for helpful conversations. The second author thanks his supervisor Jacob Rasmussen for patient guidance and helpful comments and thanks his parents for support and constant encouragement. The second author is also grateful to Yi Liu for inviting him to BICMR, Peking University, Linsheng Wang for valuable discussions on algebra, and Honghuai Fang, Zekun Chen, Fei Chen, and Shengyu Zou for the company when he was writing this paper.

2. Axioms and formal properties for sutured homology

In this section, we construct formal sutured homology and prove some basic properties.

2.1. Axioms of a Floer-type theory for closed 3-manifolds.

Let $\mathbf{Cob}^{3+1}$ be the cobordism category whose objects are closed oriented (possibly disconnected) 3-manifolds, and whose morphisms are oriented (possibly disconnected) 4-dimensional cobordisms between closed oriented 3-manifolds. Let $\mathbf{Vect}_\mathbb{F}$ be the category of $\mathbb{F}$-vector spaces, where $\mathbb{F}$ is a suitably chosen coefficient field. A $(3+1)$ dimensional topological quantum field theory, or in short $(3+1)$-TQFT, is a symmetric monoidal functor

$$\mathbf{H} : \mathbf{Cob}^{3+1} \to \mathbf{Vect}_\mathbb{F}.$$ 

For a closed oriented 3-manifold $Y$, we write $\mathbf{H}(Y)$ for the related vector space, called the $\mathbf{H}$-homology of $Y$. For an oriented cobordism $W$, we write $\mathbf{H}(W)$ for the induced map between $\mathbf{H}$-homologies of boundaries, called the $\mathbf{H}$-cobordism map associated to $W$. If $\mathbf{H}$ is fixed, then we simply write homology and cobordism map for $\mathbf{H}$-homology and $\mathbf{H}$-cobordism map, respectively.

Note that by the definition of the involved categories, we have

$$\mathbf{H}(Y_1 \sqcup Y_2) = \mathbf{H}(Y_1) \otimes_\mathbb{F} \mathbf{H}(Y_2) \text{ and } \mathbf{H}(-Y) \cong \text{Hom}_\mathbb{F}(\mathbf{H}(Y), \mathbb{F}).$$

It is well-known that Floer theories are special cases of $(3+1)$-TQFTs. Summarized from known Floer theories, we propose the following definition.

Definition 2.1. A $(3+1)$-TQFT $\mathbf{H}$ is called a Floer-type theory if it satisfies the following three Axioms (A1), (A2), and (A3).

A1. Adjunction inequality. For a closed oriented 3-manifold $Y$ and a second homology class $\alpha \in H_2(Y)$, there is a $\mathbb{Z}$-grading of $\mathbf{H}(Y)$ associated to $\alpha$, i.e., we have

$$\mathbf{H}(Y) = \bigoplus_{i \in \mathbb{Z}} \mathbf{H}(Y, \alpha, i).$$

This grading satisfies the following properties.

A1-1. For any odd integer $i$, we have $\mathbf{H}(Y, \alpha, i) = 0$.
A1-2. For $i \in \mathbb{Z}\setminus\{0\}$, the summand $\mathbf{H}(Y, \alpha, i)$ is a finite dimensional vector space over $\mathbb{F}$.
A1-3. For $i \in \mathbb{Z}$, we have $\mathbf{H}(Y, \alpha, i) \cong \mathbf{H}(Y, \alpha, -i)$. 
A1-4 (Adjunction inequality). Suppose $\Sigma$ is a connected closed oriented surface embedded in $Y$ with $g(\Sigma) \geq 1$. For $|i| > 2g(\Sigma) - 2$, we have $H(Y, [\Sigma], i) = 0$.

A1-5. If $Y$ is a surface bundle over $S^1$ such that the fibre $\Sigma$ is a connected closed oriented surface with $g(\Sigma) \geq 2$, then $H(Y, [\Sigma], 2g(\Sigma) - 2) \cong \mathbb{F}$.

A1-6. The gradings coming from multiple homology classes are compatible with each other, i.e., if we have $\alpha_1, \ldots, \alpha_n \in H_2(Y)$, then there is a $\mathbb{Z}_2$-grading on $H(Y)$, denoted by

$$H(Y) = \bigoplus_{(i_1, \ldots, i_n) \in \mathbb{Z}_2^n} H(Y, (\alpha_1, \ldots, \alpha_n), (i_1, \ldots, i_n)).$$

Moreover, we have

$$H(Y, \alpha_1 + \cdots + \alpha_n, i) = \bigoplus_{(i_1, \ldots, i_n) \in \mathbb{Z}_2^n, \ i_1 + \cdots + i_n = i} H(Y, (\alpha_1, \ldots, \alpha_n), (i_1, \ldots, i_n)).$$

A1-7. Suppose $W$ is an oriented cobordism from $Y_1$ to $Y_2$. Suppose $\alpha_1, \ldots, \alpha_n \in H_2(Y_1)$ and $\beta_1, \ldots, \beta_n \in H_2(Y_2)$ are homology classes such that for $i = 1, \ldots, n$, we have

$$\alpha_i = \beta_i \in H_2(W).$$

Then the cobordism map $H(W)$ respects the grading associated to those homology classes:

$$H(W) : H(Y_1, (\alpha_1, \ldots, \alpha_n), (i_1, \ldots, i_n)) \to H(Y_2, (\beta_1, \ldots, \beta_n), (i_1, \ldots, i_n)).$$

A2. Surgery exact triangle. Suppose $M$ is a connected compact oriented 3-manifold with toroidal boundary. Let $\gamma_1, \gamma_2, \gamma_3$ be three connected oriented simple closed curves on $\partial M$ such that

$$\gamma_1 \cdot \gamma_2 = \gamma_2 \cdot \gamma_3 = \gamma_3 \cdot \gamma_1 = -1.$$ 

Let $Y_1$, $Y_2$, and $Y_3$ be the Dehn fillings of $M$ along curves $\gamma_1$, $\gamma_2$, and $\gamma_3$, respectively. Then there is an exact triangle

$$\begin{array}{ccc}
H(Y_1) & \longrightarrow & H(Y_2) \\
\downarrow & & \downarrow \downarrow \\
H(Y_3) & \longrightarrow & \\
\end{array}$$

Moreover, maps in the above triangle are induced by the natural cobordisms associated to different Dehn fillings.

Remark 2.2. It is worth mentioning that Axioms (A1) and (A2) are enough for defining formal sutured homology for balanced sutured manifolds. The following Axiom (A3) is only involved when considering Euler characteristics.

A3 $\mathbb{Z}_2$-grading. For any closed oriented 3-manifold $Y$, there is a canonical $\mathbb{Z}_2$-grading on $H(Y)$, denoted by

$$H(Y) = H_0(Y) \oplus H_1(Y).$$

This grading satisfies the following properties.

A3-1. The $\mathbb{Z}_2$-grading is compatible with the grading in Axiom (A1). More precisely, if we have $\alpha_1, \ldots, \alpha_n \in H_2(Y)$, then there is a $\mathbb{Z}_2 \oplus \mathbb{Z}_2^n$-grading on $H(Y)$:

$$H(Y) = \bigoplus_{j \in \{0, 1\}} \bigoplus_{(i_1, \ldots, i_n) \in \mathbb{Z}_2^n} H_j(Y, (\alpha_1, \ldots, \alpha_n), (i_1, \ldots, i_n)).$$
A3-2. Suppose $\Sigma_g$ is a connected closed oriented surface of genus $g \geq 2$. Suppose $Y = S^1 \times \Sigma_g$ and $\Sigma = \{1\} \times \Sigma_g$. Then we have
\[ H(Y, [\Sigma_g], 2g - 2) = H_1(Y, [\Sigma_g], 2g - 2) \cong F. \]

A3-3. Suppose $W$ is a cobordism from $Y_1$ to $Y_2$. Then $H(W)$ is homogeneous with respect to the canonical $\mathbb{Z}_2$-grading. Its degree can be calculated by the following degree formula
\begin{equation}
\deg(H(W)) = \frac{1}{2}(\chi(W) + \sigma(W) + b_1(Y_2) - b_1(Y_1) + b_0(Y_2) - b_0(Y_1)) \pmod{2}.
\end{equation}

Remark 2.3. The canonical $\mathbb{Z}_2$-grading is essentially determined by Axioms (A3-2) and (A3-3) (c.f. [KM07 Section 25.4]). The normalization of the $\mathbb{Z}_2$-grading for the generator of $H(Y, [\Sigma_g], 2g - 2)$ is not essential. Assuming $H(Y, [\Sigma_g], 2g - 2) = H_0(Y, [\Sigma_g], 2g - 2)$ shifts the canonical $\mathbb{Z}_2$-grading for all 3-manifolds. It is worth mentioning that two existing discussions on this $\mathbb{Z}_2$-grading in [LPCS20 KM11b], adopted different normalizations.

The degrees of the maps in Axiom (A2) were described explicitly by Kronheimer and Mrowka [KM07 Section 42.3]. For the convenience of later usage, we present the discussion here.

Proposition 2.4 ([KM07 Section 42.3]). Suppose $\delta$ is a unit in $\ker(i_\omega)$ for the map
\[ i_\omega : H_1(\bar{\ell}M; \mathbb{Q}) \to H_1(M; \mathbb{Q}). \]
In the surgery exact triangle \[ \xymatrix{ H_1(\bar{\ell}M; \mathbb{Q}) \ar[r]^-{i_\omega} & H_1(M; \mathbb{Q}) \ar[r]^-{j} & \chi(M; \mathbb{Q}) \ar[r]^-{r} & H_1(\bar{\ell}M; \mathbb{Q}) }, \]
we can determine the parities of the maps $f_1$, $f_2$, and $f_3$ as follows.

1. If there is an $i = 1, 2, 3$ so that $\gamma_i \cdot \delta = 0$, then $f_{i-1}$ is odd and the other two are even.
2. If $\gamma_i \cdot \delta \neq 0$ for any $i = 1, 2, 3$, then there is a unique $j \in \{1, 2, 3\}$ so that $\gamma_j \cdot \delta$ and $\gamma_{j+1} \cdot \delta$ are of the same sign. Then the map $f_j$ is odd and the other two are even.

Here the indices are taken mod 3.

With Proposition 2.4, the following lemma is straightforward.

Lemma 2.5. In the surgery exact triangle \[ \xymatrix{ H_1(\bar{\ell}M; \mathbb{Q}) \ar[r]^-{i_\omega} & H_1(M; \mathbb{Q}) \ar[r]^-{j} & \chi(M; \mathbb{Q}) \ar[r]^-{r} & H_1(\bar{\ell}M; \mathbb{Q}) }, \]
after arbitrary shifts on the canonical $\mathbb{Z}_2$-gradings on $H(Y_i)$ for all $i = 1, 2, 3$, exactly one of the following two cases happens.

1. If all three maps $f_i$ are odd, then we have
\[ \chi(H(Y_1)) + \chi(H(Y_2)) + \chi(H(Y_3)) = 0. \]
2. If there exists $i = 1, 2, 3$ so that $f_i$ is odd and the other two are even, then
\[ \chi(H(Y_{i-1})) = \chi(H(Y_i)) + \chi(H(Y_{i+1})). \]

Here the indices are taken mod 3.

Remark 2.6. If there are no shifts, then case (2) in Lemma 2.5 happens due to Proposition 2.4.

In this paper, we discuss three Floer theories, namely, instanton (Donaldson-Floer) theory, monopole (Seiberg-Witten) theory, and Heegaard Floer theory. However, for any of these theories, we need some modifications as follows. Suppose $Y$ is an object of $\text{Cob}^{3+1}$ and $W$ is a morphism of $\text{Cob}^{3+1}$.

**Instanton theory.** We consider the decorated cobordism category $\text{Cob}_D^{3+1}$ rather than $\text{Cob}^{3+1}$. The objects are admissible pairs $(Y, \omega)$, where $\omega \subset Y'$ is a 1-cycle such that any component of $Y$ contains at least one component of $\omega$. The admissible condition means that for any component $Y_0$ of $Y$, there exists a closed oriented surface $\Sigma \subset Y_0$ such that $g(\Sigma) \geq 1$ and the algebraic intersection...
number $\omega \cdot \Sigma$ is odd. Morphisms are pairs $(W, \nu)$, where $\nu$ is a 2-cycle restricting to the given 1-cycles on $\partial W$. The $\text{H}$-homology and the $\text{H}$-cobordism map are denoted by $I^\omega(Y)$ and $I(W, \nu)$ (c.f. [Flo90a]), respectively.

It is worth mentioning that for an admissible pair $(Y, \omega)$, we need $[\omega] \neq 0 \in H^1(Y; \mathbb{Z})$ as a necessary condition (see [Flo90a]), so $b_1(Y) > 0$. Thus, strictly speaking, the objects of $\text{Cob}^{3+1}_\omega$ do not involve all closed oriented 3-manifolds.

The coefficient field is $F = \mathbb{C}$. The decorations $\omega$ and $\nu$ do not influence Axiom (A1), where the $\mathbb{Z}$-grading is induced by the generalized eigenspaces of $(\mu(\alpha), \mu(\text{pt}))$ actions for $\alpha \in H_2(Y)$ (c.f. [KM10b] Section 7).

In the original statement of the surgery exact triangle in [Flo90a], different 3-manifolds in the surgery exact triangle may have different choices of $\omega$. However, by the argument in [BS20a Section 2.2], we can assume that, in Axiom (A2), the 1-cycle $\omega$ is unchanged in all manifolds involved in the triangle.

The canonical $\mathbb{Z}_2$-grading for instanton theory was discussed by Kronheimer and Mrowka [KM10a Section 2.6]. Indeed, the degree formula (2.2) is from their discussion.

**Monopole theory.** The $\text{H}$-homology and the $\text{H}$-cobordism map are $\overline{HM}_*(Y)$ and $\overline{HM}_*(W)$ (c.f. [KM07]), respectively. Although we use $\overline{HM}_*$ for monopole theory, $(3+1)$-TQFTs associated to other versions of monopole Floer homology $\overline{HM}_*$ are also implicitly used in the proof of Floer’s excision theorem (c.f. [KM10b Section 3]), which is important to show the sutured homology for balanced sutured manifolds is well-defined.

The $\mathbb{Z}$-grading in Axiom (A1) is induced by $\langle c_1(s), \alpha \rangle$ for $s \in \text{Spin}^c(Y)$ and $\alpha \in H_2(Y)$ (c.f. [KM10b] Section 2.4)).

The coefficient field is $F = \mathbb{F}_2$. This is because originally the surgery exact triangle is only proved in characteristic two, by work of Kronheimer, Mrowka, Ozsváth, and Szabó [KMOS07]. It is worth mentioning that the surgery exact triangle with $\mathbb{Q}$ coefficients was proved by Lin, Ruberman, and Saveliev [LRS18 Section 4], and the one with $\mathbb{Z}$ coefficients was under working by Freeman [Fre]. So we can extend the discussion to $F = \mathbb{Q}$ or $\mathbb{C}$ for monopole theory. It is also worth mentioning that in [KM10a], when Kronheimer and Mrowka first introduced sutured monopole homology, they worked only with $\mathbb{Z}$ coefficients (and did not use the surgery exact triangle). The case of $\mathbb{F}_2$ coefficients was later verified by Sivek [Siv12].

The canonical $\mathbb{Z}_2$-grading for monopole theory was discussed by Kronheimer and Mrowka [KM07 Section 25.4]. When considering cobordisms of connected 3-manifolds, the degree formula (2.2) is the same as the formula in [KM07] Definition 25.4.1.

**Heegaard Floer theory.** The $\text{H}$-homology and the $\text{H}$-cobordism map are $HF^{+}(Y)$ and $HF^{+}(W)$ (c.f. [OS04d]). Similar to monopole theory, we will use other versions of Heegaard Floer homology $HF^-, HF^0, HF^-$, $HF^-$ for the proof of Floer’s excision theorem. See Section 3 for details.

The coefficient field is $F = \mathbb{F}_2$. This is because we have to use the naturality results in [JTZ18], which works only for $\mathbb{F}_2$. Originally, to obtain a $(3+1)$-TQFT, we should consider the graph cobordism category $\text{Cob}^{3+1}_\omega$ (c.f. [Zem19]) rather than $\text{Cob}^{3+1}$. However, after modifying the naturality results in Section 3, we can show the Floer homology and the cobordism maps are independent of the choice of basepoints and graphs.

For characteristic zero, the naturality results for closed 3-manifolds were obtained by Gartner in [Gar19]. However, the naturality results for cobordisms are still under working. Hence we choose to focus on characteristic two.
Similar to monopole theory, the \( \mathbb{Z} \)-grading in Axiom (A1) is induced by \( \langle c_1(s), \alpha \rangle \) for \( s \in \text{Spin}^c(Y) \) and \( \alpha \in H_2(Y) \).

There are many ways to fix the \( \mathbb{Z}_2 \)-grading for Heegaard Floer theory. See [OS04b, Section 10.4] and [FJR09, Section 2.4]. However, we can arrange the canonical \( \mathbb{Z}_2 \)-grading to be the same as those for instanton theory and monopole theory. This is possible because the degree formula (2.2) only depends on algebraic-topological information of cobordisms and 3-manifolds.

### 2.2. Formal sutured homology of balanced sutured manifolds.

In [KM10b], Kronheimer and Mrowka constructed sutured monopole homology \( SHM \) and sutured instanton homology \( SHI \) by considering closures of balanced sutured manifolds. The discussion and construction in this subsection are based on [KM10b, BS15] except for the proof of Proposition 2.11.

**Definition 2.7 (Juh06, Definition 2.2).** A balanced sutured manifold \( (M, \gamma) \) consists of a compact 3-manifold \( M \) with non-empty boundary together with a closed 1-submanifold \( \gamma \) on \( \partial M \). Let \( A(\gamma) = [-1,1] \times \gamma \) be an annular neighborhood of \( \gamma \subset \partial M \) and let \( R(\gamma) = \partial M \setminus \text{int}(A(\gamma)) \), such that they satisfy the following properties.

1. Neither \( M \) nor \( R(\gamma) \) has a closed component.
2. If \( \partial A(\gamma) = -\partial R(\gamma) \) is oriented in the same way as \( \gamma \), then we require this orientation of \( \partial R(\gamma) \) induces the orientation on \( R(\gamma) \), which is called the canonical orientation. \( \gamma \).
3. Let \( R_+(\gamma) \) be the part of \( R(\gamma) \) for which the canonical orientation coincides with the induced orientation on \( \partial M \) from \( M \), and let \( R_-(\gamma) = R(\gamma) \setminus R_+(\gamma) \). We require that \( \chi(R_+(\gamma)) = \chi(R_-(\gamma)) \). If \( \gamma \) is clear in the context, we simply write \( R_\pm = R_\pm(\gamma) \), respectively.

**Definition 2.8 ([KM10b]).** Suppose \( (M, \gamma) \) is a balanced sutured manifold. Let \( T \) be a connected compact oriented surface such that the numbers of components of \( \partial T \) and \( \gamma \) are the same. Let the preclosure \( \widetilde{M} \) of \( (M, \gamma) \) be

\[
\widetilde{M} := M \cup_{\gamma = -\partial T} [-1,1] \times T.
\]

The boundary of \( \widetilde{M} \) consists of two components

\[
\tilde{R}_+ = R_+(\gamma) \cup \{1\} \times T \quad \text{and} \quad \tilde{R}_- = R_-(\gamma) \cup \{-1\} \times T.
\]

Let \( h : \tilde{R}_+ \to \tilde{R}_- \) be a diffeomorphism which reverses the boundary orientations (i.e. preserves the canonical orientations). Let \( Y \) be the 3-manifold obtained from \( \widetilde{M} \) by gluing \( \tilde{R}_+ \) to \( \tilde{R}_- \) by \( h \) and let \( R \) be the image of \( \tilde{R}_+ \) and \( \tilde{R}_- \) in \( Y \). The pair \( (Y, R) \) is called a closure of \( (M, \gamma) \). The genus of \( R \) is called the genus of the closure \( (Y, R) \). For a closure \( (Y, R) \) with \( g(R) \geq 2 \), define

\[
H(Y|R) := H(Y, [R], 2g(R) - 2).
\]

**Remark 2.9.** For instanton theory, we also choose a point \( p \) on \( T \) and choose a diffeomorphism \( h \) such that \( h(\{1\} \times p) = \{-1\} \times p \). The image of \( [-1,1] \times p \) in \( Y \) becomes a 1-cycle \( \omega \) and we have \( \omega \cdot R = 1 \). We use \( (Y, R, \omega) \) for the definition of a closure. We do not mention this subtlety later since everything works well under this modification.

Suppose \( (Y_1, R_1) \) and \( (Y_2, R_2) \) are two closures of \( (M, \gamma) \) of the same genus. We now construct a canonical map

\[
\Phi_{12} : H(Y_1|R_1) \to H(Y_2|R_2).
\]

Note that \( Y_2 \) can be obtained from \( Y_1 \) as follows. There exists an orientation preserving diffeomorphism \( h_{12} : R_1 \to R_1 \) so that if we cut \( Y_1 \) open along \( R_1 \) and reglue using \( h_{12} \), then we obtain a
new 3-manifold $Y'_1$ together with the surface $R'_1 \subset Y'_1$. Furthermore, there exists a diffeomorphism $\phi : Y'_1 \to Y_2$ such that $\phi|_M = \text{id}_M$ and $\phi(R'_1) = R_2$.

Let $X_\phi$ be a cobordism from $Y'_1$ to $Y_2$ induced by $\phi$. It is straightforward to check

$$\mathbf{H}(X_\phi) : \mathbf{H}(Y'_1|R'_1) \to \mathbf{H}(Y_2|R_2)$$

is an isomorphism. We can regard $h_{12}$ as a composition of Dehn twists along curves on $R_1$:

$$h_{12} = D^e_{\alpha_1} \circ \cdots \circ D^e_{\alpha_n}.$$ 

Here $e_i \in \{\pm 1\}$, where $e_1 = 1$ means a positive Dehn twist, and $e_1 = -1$ means a negative Dehn twist. Suppose

$$N = \{i \mid e_i = -1\} \quad \text{and} \quad P = \{i \mid e_i = 1\}.$$ 

Note that the resulting 3-manifold of cutting $Y_1$ open along $R_1$ and regluing by $D^e_{\alpha_i}$ is the same as the resulting 3-manifold of performing a $(-e_i)$-surgery along $\alpha_i \subset R_1 \subset Y_1$. We take a neighborhood $N(R_1)$ of $R_1 \subset Y_1$, and choose an identification $N(R_1) = [-1, 1] \times R_1$. Pick

$$-1 < t_1 < \cdots < t_n < 1$$

so that $t_i \neq 0$ for $i = 1, \ldots, n$, and isotope $\alpha_i$ to the level $\{t_i\} \times R_1 \subset N(R_1) \subset Y_1$. Let $Y_P$ be the 3-manifold obtained from $Y_1$ by performing $(-1)$-surgeries along $\alpha_i$ for all $i \in P$. There is a natural cobordism $X_P$ from $Y_1$ to $Y_P$ by attaching framed 4-dimensional 2-handles to the product $[0, 1] \times Y_1$ along $\alpha_i \times \{1\}$. Furthermore, the manifold $Y_P$ can also be obtained from $Y'_1$ by performing $(-1)$-surgeries along $\alpha_i$ for all $i \in N$. Hence there is a similar cobordism $X'_N$ from $Y'_1$ to $Y_P$. Since $t_i \neq 0$, the surface $R_1 = \{0\} \times R_1$ survives in all surgeries. Let $R_P \subset Y_P$ be the corresponding surface.

**Definition 2.10** ([BS15]). Define

$$\Phi_{12} = \mathbf{H}(X_\phi) \circ \mathbf{H}(X_N)^{-1} \circ \mathbf{H}(X_P) : \mathbf{H}(Y'_1|R'_1) \to \mathbf{H}(Y_2|R_2).$$

**Proposition 2.11.** The maps

$$\mathbf{H}(X_P) : \mathbf{H}(Y'_1|R'_1) \to \mathbf{H}(Y_P|R_N) \quad \text{and} \quad \mathbf{H}(X_N) : \mathbf{H}(Y'_1|R'_1) \to \mathbf{H}(Y_P|R_P)$$

are both isomorphisms.

**Remark 2.12.** Proposition 2.11 restates [BS15, Lemma 4.9]. However, the proof in that paper involves a non-vanishing result for minimal Lefschetz fibrations. See [BS15, Proposition B.1]. Yet this non-vanishing result is not covered by Axioms (A1), (A2), and (A3), so we present an alternative proof of Proposition 2.11 based on surgery exact triangles from Axiom (A2). Also, it is worth mentioning that Baldwin and Sivek worked with $\mathbb{Z}$ coefficients for monopole theory in [BS15], while we work with $\mathbb{Z}_2$ coefficients. The choice of coefficients matters since the existing proof of the surgery exact triangle in monopole theory is only carried out in characteristic two.

**Proof of Proposition 2.11.** The cobordisms $X_P$ and $X_N$ are constructed similarly, so we only prove $X_P$ is an isomorphism. Furthermore, we can assume that $P$ has only one element $\alpha_1$. If it has more elements, then $X_P$ is simply the composition of cobordisms associated to single Dehn surgeries. With this assumption, the manifold $Y_P$ is obtained from $Y_1$ by performing a $(-1)$-surgery along
α₁. Let Y₀ be obtained from Y₁ by performing a 0-surgery along α₁, and R₁ survives to become R₀ ⊂ Y₀. Then we have an exact triangle by Axioms (A1-7) and (A2):

\[
\begin{align*}
\xymatrix{
\text{H}(Y₁|R₁) & \text{H}(Xₚ) & \text{H}(Y₁|R₀) \\
\text{H}(Y₀|R₁) \ar[ru] & \text{H}(Y₀|R₀) \ar[lu] & \text{H}(Y₀|R₀) \ar[u] 
}
\end{align*}
\]

To show that H(Xₚ) is an isomorphism, it suffices to show that H(Y₀|R₀) = 0. Indeed, since Y₀ is obtained from a 0-surgery along α₀, and α₀ can be isotoped to be a simple closed curve on R₁, the surface R₀ ⊂ Y₀ is compressible. Hence H(Y₀|R₀) = 0 by the adjunction inequality in Axiom (A1-4).

With Proposition 2.11 settled down, the rest of the argument in [BS15] can be applied to our setup verbatim, and we have the following theorem.

**Theorem 2.13 ([BS15]).** Suppose (M, γ) is a balanced sutured manifold and (Y₁, R₁) and (Y₂, R₂) are two closures of the same genus. Then the isomorphism

\[\Phi_{12} : H(Y₁|R₁) → H(Y₂|R₂)\]

defined in Definition 2.10 satisfies the following properties.

1. The map \(\Phi_{12}\) is well-defined up to multiplication by a unit in \(\mathbb{F}\).
2. If \((Y₁, R₁) = (Y₂, R₂)\), then \(\Phi_{12} = id\).
3. If there is a third closure \((Y₃, R₃)\) of the same genus, then we have \(\Phi_{13} = \Phi_{23} \circ \Phi_{12}\).

**Remark 2.14.** In Baldwin and Sivek’s original work, the requirement that the two closures have the same genus could be dropped, at the cost of involving local coefficient systems. However, up to the authors’ knowledge, the discussion for the naturality of Heegaard Floer theory has not been carried out with local coefficients. Since it is enough to work with closures of a large and fixed closure in the current paper, we choose not to discuss the local coefficients.

**Definition 2.15 ([JTZ18, BS15]).** A projectively transitive system of vector spaces over a field \(\mathbb{F}\) consists of

1. a set \(A\) and collection of vector spaces \(\{V_\alpha\}_{\alpha \in A}\) over \(\mathbb{F}\),
2. a collection of linear maps \(\{g_\beta^\alpha\}_{\alpha, \beta \in A}\) well-defined up to multiplication by a unit in \(\mathbb{F}\) such that
   (a) \(g_\beta^\alpha\) is an isomorphism from \(V_\alpha\) to \(V_\beta\) for any \(\alpha, \beta \in A\), called a canonical map,
   (b) \(g_\alpha^\alpha = id_{V_\alpha}\) for any \(\alpha \in A\),
   (c) \(g_\gamma^\beta \circ g_\beta^\alpha = g_\gamma^\alpha\) for any \(\alpha, \beta, \gamma \in A\).

A morphism of projectively transitive systems of vector spaces over a field \(\mathbb{F}\) from \((A, \{V_\alpha\}, \{g_\beta^\alpha\})\) to \((B, \{U_\gamma\}, \{h_\gamma^\delta\})\) is a collection of maps \(\{f_\alpha^\beta\}_{\alpha \in A, \gamma \in B}\) such that

1. \(f_\alpha^\beta\) is a linear map from \(V_\alpha\) to \(U_\gamma\) well-defined up to multiplication by a unit in \(\mathbb{F}\) for any \(\alpha \in A\) and \(\gamma \in B\),
2. \(f_\delta^\beta \circ g_\beta^\alpha = h_\gamma^\delta \circ f_\alpha^\gamma\) for any \(\alpha, \beta \in A\) and \(\gamma, \delta \in B\).
A transitive system of vector spaces over a field $\mathbb{F}$ if it is a projectively transitive system and all equations with $\doteq$ are replaced by ones with $=$. A morphism of transitive systems of vector spaces over a field $\mathbb{F}$ is defined similarly.

We can replace vector spaces with groups or chain complexes of vector spaces and define the projectively transitive system and the transitive system similarly.

**Remark 2.16.** A transitive system of vector spaces $(A, \{V_\alpha\}, \{g_\beta^\alpha\})$ over a field $\mathbb{F}$ canonically defines an actual vector space over $\mathbb{F}$

$$V := \bigsqcup_{\alpha \in A} V_\alpha / \sim,$$

where $v_\alpha \sim v_\beta$ if and only if $g_\beta^\alpha(v_\alpha) = v_\beta$ for any $v_\alpha \in V_\alpha$ and $v_\beta \in V_\beta$. A morphism of transitive systems of vector spaces canonically defines an linear map between corresponding actual vector spaces.

**Convention.** If $\mathbb{F} = \mathbb{F}_2$, a projectively transitive system over $\mathbb{F}$ is simply a transitive system since $\mathbb{F}_2$ has only one unit. In this case, we do not distinguish the projectively transitive system, the transitive system and the corresponding actual vector space. For a general field $\mathbb{F}$, the morphisms between projectively transitive systems are also called maps.

**Definition 2.17.** Suppose $H$ is a $(3+1)$-TQFT satisfying Axioms (A1) and (A2), and $(M, \gamma)$ is a balanced sutured manifold, the formal sutured homology $\text{SH}^g(M, \gamma)$ is the projectively transitive system consisting of

(1) the $H$-homology $H(Y|\mathcal{R})$ for closures $(Y, \mathcal{R})$ of $(M, \gamma)$ with a fixed and large enough genus $g$.

(2) the canonical maps $\Phi$ between $H$-homologies as in Definition 2.10.

**Convention.** Throughout the paper, when discussing formal sutured homology, we will pre-fix a large enough genus. So we omit it from the notation and write simply $\text{SH}(M, \gamma)$ instead of $\text{SH}^g(M, \gamma)$.

**Remark 2.18.** When $H$ also satisfies Axiom (A3), since $\Phi$ is constructed by cobordism maps and their inverses, it is homogeneous with respect to the $\mathbb{Z}_2$-grading from Axiom (A3). Then there exists an induced relative $\mathbb{Z}_2$-grading on $\text{SH}(M, \gamma)$.

In [BS16a, BS18], Baldwin and Sivek proved the bypass exact triangle for sutured monopole homology and sutured instanton homology. Their proof can be exported to our setup.

**Theorem 2.19** ([BS16a, Theorem 5.2] and [BS18, Theorem 1.20]). Suppose $(M, \gamma_1), (M, \gamma_2), (M, \gamma_3)$ are three balanced sutured manifold such that the underlying 3-manifold is the same, and the sutures $\gamma_1, \gamma_2$, and $\gamma_3$ only differ in a disk as depicted in Figure 1. Then there exists an exact triangle

$$
\begin{align*}
\text{SH}(-M, -\gamma_1) & \xrightarrow{\psi_1} \text{SH}(-M, -\gamma_2) & \xrightarrow{\psi_2} \text{SH}(-M, -\gamma_3) \\
\xrightarrow{\psi_3} & \xrightarrow{\psi_2} & \xrightarrow{\psi_3}
\end{align*}
$$

Moreover, the maps $\psi_i$ are induced by cobordisms and hence are homogeneous with respect to the relative $\mathbb{Z}_2$-grading on $\text{SH}(M, \gamma_i)$.

We un-package the proof of Theorem 2.19 for later convenience.
Proposition 2.20 ([BS16a, Section 5] and [BS18, Section 4]). Consider $(M, \gamma_i)$ for $i = 1, 2, 3$ in Theorem 2.19, there is a closure $(Y_1, R)$ of $(-M, -\gamma_1)$ with the following significance.

1. The genus $g(R)$ is large enough.
2. There are pairwise disjoint curves $\zeta_1, \zeta_2, \zeta_3 \subset Y_1$ so that the following is true.
   (a) For $i = 1, 2, 3$, we have $\zeta_i \cap \text{int}(M) = \emptyset$ and $\zeta_i$ can be isotoped to be disjoint from $R$.
   (b) If we perform a suitable Dehn surgery along $\zeta_1$, then we obtain a closure $(Y_2, R)$ of $(-M, -\gamma_2)$. If we perform a suitable Dehn surgery in $Y_2$ along $\zeta_2$, then we obtain a closure $(Y_3, R)$ of $(-M, -\gamma_3)$. If we perform a suitable Dehn surgery in $Y_3$ along $\zeta_3$, then we obtain the closure $(Y_1, R)$ of $(-M, -\gamma_1)$ again.
   (c) The maps $\psi_1, \psi_2,$ and $\psi_3$ are induced the cobordism associated to Dehn surgeries along $\zeta_1, \zeta_2,$ and $\zeta_3$, respectively.
3. There are two curves $\eta_1$ and $\eta_2$ on $R$, so that if we perform $(-1)$-surgeries on both of them, with respect to the surface framings from $R$, then the surgeries along $\zeta_1, \zeta_2,$ and $\zeta_3$ as stated in (b) lead to an exact triangle as in Axiom (A2).

2.3. Gradings on formal sutured homology.

Suppose $(M, \gamma)$ is a balanced sutured manifold and $S \subset (M, \gamma)$ is a properly embedded surface in $M$. If $S$ satisfies some admissible conditions, the first author [Li19] constructed a $\mathbb{Z}$-grading on $SHM(M, \gamma)$ and $SHI(M, \gamma)$. In this subsection, we adapt the construction to formal sutured homology $SH(M, \gamma)$.

Definition 2.21 ([GL19]). Suppose $(M, \gamma)$ is a balanced sutured manifold and $S \subset M$ is a properly embedded surface. The surface $S$ is called an admissible surface if the following holds.

1. Every boundary component of $S$ intersects $\gamma$ transversely and nontrivially.
2. $\frac{1}{2}|S \cap \gamma| - \chi(S)$ is an even integer.

Recall the construction of a closure of $(M, \gamma)$ in Definition 2.8. Let $T$ be a connected compact oriented surface of large enough genus and $\partial T \cong -\gamma$. Then we take $\widetilde{M} = M \cup [-1, 1] \times T$, with $\partial \widetilde{M} = \tilde{R}_+ \sqcup (-\tilde{R}_{-})$.

Suppose $n = \frac{1}{2}|\partial S \cap \gamma|$ and $\partial S \cap \gamma = \{p_1, \ldots, p_{2n}\}$. 

![Diagram](image-url)
Definition 2.22 (Li19). A pairing $\mathcal{P}$ of size $n$ is a collection of $n$ couples $\mathcal{P} = \{(i_1, j_1), \ldots, (i_n, j_n)\}$ such that the following holds.

1. $\{1, \ldots, 2n\} = \{i_1, j_1, \ldots, i_n, j_n\}$.
2. For any $k \in \{1, \ldots, n\}$, the points $p_{i_k}$ and $p_{j_k}$ are positive and negative, respectively, as intersection points of oriented curves $\partial S$ and $\gamma$ on $\partial M$.

Given a pairing $\mathcal{P}$ of size $n$, and assuming that $g(T)$ is large enough, we can extend $S$ to a properly embedded surface in $\tilde{M}$ as follows. Let $\alpha_1, \ldots, \alpha_n$ be pairwise disjoint properly embedded arcs on $T$ such that the following holds.

1. The arcs $\alpha_1, \ldots, \alpha_n$ represent linearly independent homology classes in $H_1(T, \partial T)$.
2. For any $k \in \{1, \ldots, n\}$, we have $\partial \alpha_i = \{p_{i_k}, p_{j_k}\}$.

Given such $\alpha_1, \ldots, \alpha_n$, take $r: S \to \mathbb{R}$.

Then $\tilde{S}_P$ is a properly embedded surface inside $\tilde{M}$.

Definition 2.23. A pairing $\mathcal{P}$ is called balanced if $\tilde{S}_P \cap \tilde{R}_+$ and $\tilde{S}_P \cap \tilde{R}_-$ have the same number of components.

For any balanced pairing $\mathcal{P}$, we can pick an orientation preserving diffeomorphism $h: \tilde{R}_+ \xrightarrow{\cong} \tilde{R}_-$ so that

$$h(\tilde{S}_P \cap \tilde{R}_+) = \tilde{S}_P \cap \tilde{R}_-.$$ 

Thus, we obtain a closed oriented surface $\tilde{S}_P \subset Y$ in the closure $(Y, R)$ induced by $h$. Define

$$\text{SH}(M, \gamma, S, i) := H(Y, ([R], [\tilde{S}_P]), (2g(R) - 2, 2i)).$$

Theorem 2.24. Given an admissible surface $S$ in a balanced sutured manifold $(M, \gamma)$, the decomposition

$$\text{SH}(M, \gamma) = \bigoplus_{i \in \mathbb{Z}} \text{SH}(M, \gamma, S, i)$$

is independent of all the choices made in the construction and hence is well-defined.

Remark 2.25. As mentioned in the convention after Definition 2.17 when writing $\text{SH}$, we actually mean $\text{SH}^g$ for some large and fixed integer $g$. This means that all closures involved have the same genus $g$.

Proof of Theorem 2.24. The decomposition follows from Axioms (A1-1) and (A1-7). This gives a $\mathbb{Z}$-grading on $\text{SH}(M, \gamma)$. To show that this grading is well-defined, we need to show that it is independent of the following three types of choices:

1. the choice of the balanced pairing $\mathcal{P}$,
2. the choice of arcs $\alpha_1, \ldots, \alpha_n$ with fixed endpoints,
3. the choice of the diffeomorphism $h$.

In Li19 Section 3.1, the grading has been shown to be independent of the choices of type (2) and (3). The proof involves only Axioms (A1) and (A2) and hence can be applied to our current setup. However, the original argument for choices of type (1) in Li19 Section 3.3 involves closures...
of different genus, which is beyond the scope of our current paper as mentioned in Remark 2.14. Hence, we provide an alternative proof here. For the moment, let us write the grading as

\[ \text{SH}(M, \gamma, S, \mathcal{P}, i) \]

to emphasize that the grading a priori depends on the choice of the balanced pairing. Theorem 2.24 then follows from the following proposition.

**Proposition 2.26.** Suppose \( \mathcal{P} \) and \( \mathcal{P}' \) are two balanced pairings, then for any \( i \in \mathbb{Z} \), we have

\[ \text{SH}(M, \gamma, S, \mathcal{P}, i) = \text{SH}(M, \gamma, S, \mathcal{P}', i). \]

To relate two different pairings, in [Li19], the author introduced the following operation.

**Definition 2.27.** Suppose \( \mathcal{P} \) is a pairing of size \( n \) and \( \alpha_1, \ldots, \alpha_n \) are related arcs. Suppose \( k, l \in \{1, \ldots, n\} \) are two indices so that the following holds.

1. The arcs \( \{1\} \times \alpha_{ik} \) and \( \{1\} \times \alpha_{il} \) belong to different components of \( \tilde{S}_\mathcal{P} \cap R_+ \).
2. The arcs \( \{-1\} \times \alpha_{ik} \) and \( \{-1\} \times \alpha_{il} \) belong to different components of \( \tilde{S}_\mathcal{P} \cap R_- \).

Then we can construct another pairing

\[ \mathcal{P}' = (\mathcal{P}\setminus\{(i_k, j_k), (i_l, j_l)\}) \cup \{(i_k, j_l), (i_l, j_k)\}. \]

The operation of replacing \( \mathcal{P} \) by \( \mathcal{P}' \) is called a cut and glue operation.

**Theorem 2.28 ([Kav19]).** Balanced pairings always exist. Moreover, any two balanced pairings are related by a finite sequence of cut and glue operations and their inverses.

**Lemma 2.29.** Suppose \( \mathcal{P} \) and \( \mathcal{P}' \) are two balanced pairings that are related by a cut and glue operation, then for any \( i \in \mathbb{Z} \), we have

\[ \text{SH}(M, \gamma, S, \mathcal{P}, i) = \text{SH}(M, \gamma, S, \mathcal{P}', i). \]

**Proof.** Suppose \( k \) and \( l \) are the indices involved in the operation. From the first part of the proof of Theorem 2.24 we can freely make choices of type (2) and (3). Hence we can assume that there is a disk \( D \subset \text{int}(T) \) so that \( \alpha_k \) and \( \alpha_l \) intersect \( D \) in two arcs as depicted in Figure 2. Suppose \( D_+ = \{1\} \times D \subset R_+ \) and \( D_- = \{-1\} \times D \subset R_- \).

We can choose an orientation preserving diffeomorphism \( h : \tilde{R}_+ \cong \tilde{R}_- \) such that

\[ h(\tilde{S}_\mathcal{P} \cap \tilde{R}_+) = \tilde{S}_{\mathcal{P}'} \cap \tilde{R}_- \text{ and } h(D_+) = D_- \]

Let \( (Y, R) \) be the corresponding closure of \( (M, \gamma) \) and \( \tilde{S}_\mathcal{P} \) be the closed surface defining the grading \( \text{SH}(M, \gamma, S, \mathcal{P}) \). Let \( \beta_k = \alpha_k \cap D \) and \( \beta_l = \alpha_l \cap D \). It is straightforward to check that if we remove the two arcs \( \beta_k \) and \( \beta_l \) from \( D \subset T \), and glue back two new arcs \( \beta'_k \) and \( \beta'_l \) as shown in the middle subfigure of Figure 2, then we obtain two new properly embedded arcs \( \alpha'_k \) and \( \alpha'_l \) on \( T \) so that

\[ \partial \alpha'_k = \{p_{i_k}, p_{j_k}\} \text{ and } \partial \alpha'_l = \{p_{i_l}, p_{j_l}\}. \]

Hence we change from \( \mathcal{P} \) to \( \mathcal{P}' \). Inside \( Y \), if we remove \( S^1 \times (\beta_k \cup \beta_l) \subset S^1 \times D \subset Y \) and glue back \( S^1 \times (\beta'_k \cup \beta'_l) \subset S^1 \times D \), then we obtain the surface \( \tilde{S}_{\mathcal{P}'} \subset Y \) that gives rise to the grading \( \text{SH}(M, \gamma, S, \mathcal{P}') \). The lemma then follows from the fact

\[ [\tilde{S}_{\mathcal{P}'}] = [\tilde{S}_\mathcal{P}] \in H_2(Y). \]
The equality (2.5) can be proved by constructing an explicit cobordism in $Y^{\hat{r},1}$ from $S^1 \times (\beta_1 \cup \beta_2) \times [0,1] \subset S^1 \times D \times [0,1] \subset Y \times [0,1]$
and glue back $S^1 \times U \subset D \times [0,1]$, where $U \subset D \times [0,1]$ is the surface shown in the right subfigure of Figure 2.

**Figure 2.** The disk $D$, the arcs $\beta_k, \beta_l, \beta_k', \beta_l'$, and the surface $U$.  

The equality (2.5) can be proved by constructing an explicit cobordism in $Y^{\hat{r},1}$ from $S^1 \subset Y \times \{0\}$ to $S^1 \subset Y \times \{1\}$: in the product $(Y \times [0,1], S^1 \times [0,1])$, we can remove $S^1 \times (\beta_1 \cup \beta_2) \times [0,1] \subset S^1 \times D \times [0,1] \subset Y \times [0,1]$
and glue back $S^1 \times U \subset D \times [0,1]$, where $U \subset D \times [0,1]$ is the surface shown in the right subfigure of Figure 2.

**Proof of Proposition 2.26.** It follows immediately from Theorem 2.28 and Lemma 2.29.

Having constructed the grading, the rest of the arguments in [Li19, Section 3.3] can be applied to our current setup verbatim. Hence we have the following.

**Theorem 2.30 ([Li19, Li18]).** Suppose $(M, \gamma)$ is a balanced sutured manifold and $S \subset (M, \gamma)$ is an admissible surface. Then there is a $\mathbb{Z}$-grading on $SH(M, \gamma)$ induced by $S$, which we write as

$$SH(M, \gamma) = \bigoplus_{i \in \mathbb{Z}} SH(M, \gamma, S, i).$$

This decomposition satisfies the following properties.

1. Suppose $n = \frac{1}{2}|\partial S \cap \gamma|$. If $|i| > \frac{1}{2}(n - \chi(S))$, then $SH(M, \gamma, S, i) = 0$.

2. If there is a sutured manifold decomposition $(M, \gamma) \xrightarrow{S} (M', \gamma')$ in the sense of Gabai [Gab83], then we have

$$SH(M, \gamma, S, \frac{1}{2}(n - \chi(S))) \cong SH(M', \gamma').$$

3. For any $i \in \mathbb{Z}$, we have

$$SH(M, \gamma, S, i) = SH(M, \gamma, -S, -i).$$

4. For any $i \in \mathbb{Z}$, we have

$$SH(M, -\gamma, S, i) = SH(M, \gamma, S, -i).$$

5. For any $i \in \mathbb{Z}$, we have

$$SH(-M, \gamma, S, i) \cong Hom_{\mathbb{F}}(SH(M, \gamma, S, -i), \mathbb{F}).$$

**Proof.** Term (1) comes from the adjunction inequality in (A1-4). Term (2) is a restatement of [KM10b, Proposition 7.11]. Term (3) is straightforward from the definition. Term (4) is from Axiom (A1-3). Term (5) is from the pairing (c.f. [Li18]):

$$\langle \cdot, \cdot \rangle : SH(M, \gamma) \times SH(-M, \gamma) \to \mathbb{F}$$
Based on the term (2) in Theorem 2.30, we can show formal sutured homology detects the tautness and the productness of balanced sutured manifolds.

**Definition 2.31** ([Juh06]). A sutured manifold \((M, \gamma)\) is called **taut** if \(M\) is irreducible and \(R_+(\gamma)\) and \(R_-(\gamma)\) are both incompressible and Thurston norm-minimizing in the homology class that they represent in \(H_2(M, \gamma)\).

**Theorem 2.32** ([Juh06, Juh08, KM10b]). Suppose \((M, \gamma)\) is a balanced sutured manifold so that \(M\) is irreducible. Then \((M, \gamma)\) is taut if and only if \(\text{SH}(M, \gamma) \neq 0\).

**Definition 2.33.** Suppose \((M, \gamma)\) is a balanced sutured manifold. It is called a **homology product** if \(H_1(M, R_+(\gamma)) = 0\) and \(H_1(M, R_-(\gamma)) = 0\). It is called a **product sutured manifold** if \((M, \gamma) \cong ([\pm 1, 1] \times \Sigma, \{0\} \times \partial \Sigma)\), where \(\Sigma\) is a compact surface with boundary.

**Theorem 2.34** ([Ni07, Juh08, KM10b]). Suppose \((M, \gamma)\) is a sutured manifold and a homology product. Then \((M, \gamma)\) is a product sutured manifold if and only if \(\text{SH}(M, \gamma) \cong \mathbb{F}\).

**Remark 2.35.** Theorem 2.34 is irrelevant to the proof of the main theorem in this paper, though it is itself a very important property of Floer theory. It has proofs in different versions of Floer theories, though the one Kronheimer and Mrowka [KM10b] introduced in instanton theory depends only on some topological facts and the formal properties of Floer theory, i.e., Axiom (A1), especially the adjunction inequality (A1-4).

If \(S \subset (M, \gamma)\) is not admissible, then we can perform an isotopy on \(S\) to make it admissible.

**Definition 2.36.** Suppose \((M, \gamma)\) is a balanced sutured manifold, and \(S\) is a properly embedded surface. A **stabilization** of \(S\) is a surface \(S_1\) obtained from \(S\) by isotopy in the following sense. This isotopy creates a new pair of intersection points:

\[
\partial S' \cap \gamma = (\partial S \cap \gamma) \cup \{p_+, p_-\}.
\]

We require that there are arcs \(\alpha \subset \partial S'\) and \(\beta \subset \gamma\), oriented in the same way as \(\partial S'\) and \(\gamma\), respectively, and the following holds.

1. \(\partial \alpha = \partial \beta = \{p_+, p_-\}\).
2. \(\alpha\) and \(\beta\) cobound a disk \(D\) with \(\text{int}(D) \cap (\gamma \cup \partial S') = \emptyset\).

The stabilization is called **negative** if \(\partial D\) is the union of \(\alpha\) and \(\beta\) as an oriented curve. It is called **positive** if \(\partial D = (-\alpha) \cup \beta\). See Figure 3. We denote by \(S^{\pm k}\) the surface obtained from \(S\) by performing \(k\) positive or negative stabilizations, respectively.

The following lemma is straightforward.

**Lemma 2.37.** Suppose \((M, \gamma)\) is a balanced sutured manifold, and \(S\) is a properly embedded surface. Suppose \(S^+\) and \(S^-\) are obtained from \(S\) by performing a positive and a negative stabilization, respectively. Then we have the following.

1. If we decompose \((M, \gamma)\) along \(S\) or \(S^+\) (c.f. [Gab83, Section 3] and [Juh08, Definition 2.7]), then the resulting two balanced sutured manifolds are diffeomorphic.
2. If we decompose \((M, \gamma)\) along \(S^-\), then the resulting balanced sutured manifold \((M', \gamma')\) is not taut, as \(R_\pm (\gamma')\) both become compressible.
Remark 2.38. The definition of stabilizations of a surface depends on the orientations of the suture and the surface. If we reverse the orientation of the suture or the surface, then positive and negative stabilizations switch between each other.

One can also relate the gradings associated to different stabilizations of a fixed surface. The proof for SHM and SHI in [Li19] [Wan20] can be adapted to our setup as well.

**Theorem 2.39** ([Li19 Proposition 4.3] and [Wan20 Proposition 4.17]). Suppose $(M, \gamma)$ is a balanced sutured manifold and $S$ is a properly embedded surface in $M$ that intersects $\gamma$ transversely. Suppose all the stabilizations mentioned below are performed on a distinguished boundary component of $S$. Then, for any $p, k, l \in \mathbb{Z}$ such that the stabilized surfaces $S^p$ and $S^{p+2k}$ are both admissible, we have

$$\text{SH}(M, \gamma, S^p, l) = \text{SH}(M, \gamma, S^{p+2k}, l + k).$$

Note that $S^p$ is a stabilization of $S$ as introduced in Definition 2.36, and, in particular, $S^0 = S$.

If we have multiple admissible surfaces, then they together induce a multi-grading. This is proved for SHM and SHI by Ghosh and the first author [GL19]. The proof can be adapted to our case without essential changes.

**Theorem 2.40** ([GL19 Proposition 1.14]). Suppose $(M, \gamma)$ is a balanced sutured manifold and $S_1, \ldots, S_n$ are admissible surfaces in $(M, \gamma)$. Then there exists a $\mathbb{Z}^n$-grading on $\text{SH}(M, \gamma)$ induced by $S_1, \ldots, S_n$, which we write as

$$\text{SH}(M, \gamma) = \bigoplus_{(i_1, \ldots, i_n) \in \mathbb{Z}^n} \text{SH}(M, \gamma, (S_1, \ldots, S_n), (i_1, \ldots, i_n)).$$

**Theorem 2.41** ([GL19 Theorem 1.12]). Suppose $(M, \gamma)$ is a balanced sutured manifold and $\alpha \in H_2(M, \partial M)$ is a nontrivial homology class. Suppose $S_1$ and $S_2$ are two admissible surfaces in $(M, \gamma)$ such that

$$[S_1] = [S_2] = \alpha \in H_2(M, \partial M).$$

Then, there exists a constant $C$ so that

$$\text{SH}(M, \gamma, S_1, l) = \text{SH}(M, \gamma, S_2, l + C).$$
Based on the relative $\mathbb{Z}_2$-grading from Remark 2.18 and the $\mathbb{Z}_n$-grading from Theorem 2.40, we can define graded Euler characteristic of formal sutured homology.

**Definition 2.42.** Suppose $(M, \gamma)$ is a balanced sutured manifold and $S_1, \ldots, S_n$ are admissible surfaces in $(M, \gamma)$ such that $[S_1], \ldots, [S_n]$ generate $H_2(M, \partial M)$. For $i = 1, \ldots, n$, let $\rho_i \in H = H_1(M)/\text{Tors}$ be the class satisfying $\rho_i \cdot S_j = \delta_{i,j}$. Define the **graded Euler characteristic** of $SH(M, \gamma)$ to be

$$\chi_{\text{gr}}(SH(M, \gamma)) := \sum_{(i_1, \ldots, i_n) \in \mathbb{Z}^n} \chi(SH(M, \gamma, (S_1, \ldots, S_n, (i_1, \ldots, i_n)))) \cdot (\rho_1^{i_1} \cdots \rho_n^{i_n}) \in \mathbb{Z}[H]/\pm H.$$ 

**Remark 2.43.** It can be shown by Theorem 2.41 that the definition of graded Euler characteristic is independent of the choice of $S_1, \ldots, S_n$ if we regard it as an element in $\mathbb{Z}[H]/\pm H$. If the admissible surfaces $S_1, \ldots, S_n$ and a particular closure of $(M, \gamma)$ is fixed, then the ambiguity of $\pm H$ can be removed.

From Theorem 2.19, Proposition 2.20, and Axiom (A1-7), the following proposition is straightforward.

**Proposition 2.44.** Suppose $(M, \gamma)$ is a balanced sutured manifold and $S \subset (M, \gamma)$ is an admissible surface. Suppose the disk as in Figure 7 where we perform the bypass change, is disjoint from $\partial S$. Let $\gamma_2$ and $\gamma_3$ be the resulting two sutures. Then all the maps in the bypass exact triangle (2.4) are grading preserving, i.e., for any $i \in \mathbb{Z}$, we have an exact triangle

$$
\begin{array}{ccc}
SH(-M, -\gamma_1, S, i) & \xrightarrow{\psi_{1,i}} & SH(-M, -\gamma_2, S, i) \\
\downarrow \psi_{3,i} & & \downarrow \psi_{3,i} \\
SH(-M, -\gamma_3, S, i) & \xleftarrow{\psi_{2,i}} & SH(-M, -\gamma_2, S, i)
\end{array}
$$

where $\psi_{k,i}$ are the restriction of $\psi_k$ in (2.4).

### 3. Heegaard Floer homology and the graph TQFT

In this section, we discuss the modification of Heegaard Floer theory to make it suitable to formal sutured homology.

#### 3.1. Heegaard Floer homology for multi-pointed 3-manifolds.

In this subsection and the next subsection, we provide an overview of the graph TQFT for Heegaard Floer theory, constructed by Zemke [Zem19] (see also [HMZ18, Zem18]), and list some properties which are relevant to proofs in the third subsection about Floer’s excision theorem.

**Definition 3.1.** A **multi-pointed 3-manifold** is a pair $(Y, w)$ consisting of a closed, oriented 3-manifold $Y$ (not necessarily connected), together with a finite collection of basepoints $w \subset Y$, such that each component of $Y$ contains at least one basepoint.

Given two multi-pointed 3-manifolds $(Y_1, w_1)$ and $(Y_2, w_2)$, a **ribbon graph cobordism** from $(Y_1, w_1)$ to $(Y_2, w_2)$ is a pair $(W, \Gamma)$ satisfying the following conditions.

1. $W$ is a cobordism from $Y_1$ to $Y_2$.
2. $\Gamma$ is an embedded graph in $W$ such that $\Gamma \cap Y_i = w_i$ for $i = 1, 2$. Furthermore, each point of $w_i$ has valence 1 in $\Gamma$.
3. $\Gamma$ has finitely many edges and vertices, and no vertices of valence 0.
4. The embedding of $\Gamma$ is smooth on each edge.
(5) $\Gamma$ is decorated with a formal ribbon structure, i.e., a formal choice of cyclic ordering of the edges adjacent to each vertex.

**Definition 3.2.** A restricted graph is a graph whose vertices have valence either 1 or 2. A ribbon graph cobordism $(W, \Gamma)$ from $(Y_1, \mathbf{w}_1)$ to $(Y_2, \mathbf{w}_2)$ is called a restricted graph cobordism if $\Gamma$ is restricted (so the cyclic ordering is unique) and any component of $\Gamma$ does not connect two basepoints of the same manifold $Y_i$ for $i = 1, 2$.

**Definition 3.3** ([Zen19, Definition 4.1]). Suppose $(Y, \mathbf{w})$ is a connected multi-pointed 3-manifold. A multi-pointed Heegaard diagram $\mathcal{H} = (\Sigma, \alpha, \beta, \mathbf{w})$ for $(Y, \mathbf{w})$ is a tuple satisfying the following conditions.

1. $\Sigma$ is a closed, oriented surface, embedded in $Y$, such that $\mathbf{w} \subset \Sigma \setminus (\alpha \cup \beta)$. Furthermore, $\Sigma$ splits $Y$ into two handlebodies $U_\alpha$ and $U_\beta$, oriented so that $\Sigma = \partial U_\alpha = -U_\beta$.

2. $\alpha = \{\alpha_1, \ldots, \alpha_n\}$ is a collection of $n = g(\Sigma) + |\mathbf{w}| - 1$ pairwise disjoint simple closed curves on $\Sigma$, bounding pairwise disjoint compressing disks in $U_\alpha$. Each component of $\Sigma \setminus \alpha$ is planar and contains a single basepoint.

3. $\beta = \{\beta_1, \ldots, \beta_n\}$ is a collection of pairwise disjoint, simple, closed curves on $\Sigma$ bounding pairwise disjoint compressing disks in $U_\beta$. Each component of $\Sigma \setminus \beta$ is planar and contains a single basepoint.

Suppose $\mathbf{w} = \{w_1, \ldots, w_m\}$. Let the polynomial ring associated to $\mathbf{w}$ be

$$\mathbb{F}_2[U_{\mathbf{w}}] := \mathbb{F}_2[U_{w_1}, \ldots, U_{w_m}]$$

Let $\mathbb{F}_2[U_{\mathbf{w}}, U_{\mathbf{w}}^{-1}]$ be the ring obtained by formally inverting each of the variables.

If $k = (k_1, \ldots, k_m)$ is an $m$-tuple, let

$$U_{\mathbf{w}}^k := U_{w_1}^{k_1} \cdots U_{w_m}^{k_m}$$

For simplicity, we will also write $U_i$ for $U_{w_i}$.

Suppose $\mathcal{H} = (\Sigma, \alpha, \beta, \mathbf{w})$ is a multi-pointed Heegaard diagram of a connected multi-pointed 3-manifold $(Y, \mathbf{w})$. Suppose $n = g(\Sigma) + |\mathbf{w}| - 1$. Consider two tori

$$T_\alpha := \alpha_1 \times \cdots \times \alpha_n \text{ and } T_\beta := \beta_1 \times \cdots \times \beta_n$$

in the symmetric product

$$\text{Sym}^n \Sigma := \left(\prod_{i=1}^n \Sigma\right)/S_n.$$

The chain complex $CF^-(\mathcal{H})$ is a free $\mathbb{F}_2[U_{\mathbf{w}}]$-module generated by intersection points $x \in T_\alpha \cap T_\beta$. Define

$$CF^\infty(\mathcal{H}) := CF^-(\mathcal{H}) \otimes_{\mathbb{F}_2[U_{\mathbf{w}}]} \mathbb{F}_2[U_{\mathbf{w}}, U_{\mathbf{w}}^{-1}]$$

and

$$CF^+(\mathcal{H}) := CF^\infty(\mathcal{H})/CF^-(\mathcal{H}).$$

To construct a differential on $CF^-(\mathcal{H})$, suppose $\mathcal{H}$ satisfies some extra admissibility conditions if $b_1(Y) > 0$ (c.f. [Zen19, Section 4.7]). Let $(J_x)_{x \in [0,1]}$ be an auxiliary path of almost complex structures on $\text{Sym}^n \Sigma$ and let $\pi_2(x, y)$ be the set of homology classes of Whitney disks connecting intersection points $x$ and $y$ (c.f. [OS08, Section 3.4]). For $\phi \in \pi_2(x, y)$, let $\mathcal{M}_{J_x}(\phi)$ be the moduli space of $J_x$-holomorphic maps $u : [0,1] \times \mathbb{R} \to \text{Sym}^n \Sigma$ which represent $\phi$. The moduli space $\mathcal{M}_{J_x}(\phi)$ has a natural action of $\mathbb{R}$, corresponding to reparametrization of the source. We write

$$\widehat{\mathcal{M}}_{J_x}(\phi) := \mathcal{M}_{J_x}(\psi)/\mathbb{R}.$$
For $\phi \in \pi_2(x, y)$, let $\mu(\phi)$ be the expected dimension of $M_{J_\phi}(\phi)$ for generic $J_\phi$ and let $n_{w_\phi}(\phi)$ be the algebraic intersection number of $\{w_i\} \times \text{Sym}^{-1}\Sigma$ and any representative of $\phi$. Define

$$n_w(\phi) := (n_{w_1}(\phi), \ldots, n_{w_m}(\phi)).$$

For a generic path $J$, define the differential on $CF^-(\mathcal{H})$ by

$$\partial_{J_\phi}(x) = \sum_{y \in T_\phi \cap T_\phi \phi \in \pi_2(x, y)} \sum_{\mu(\phi) = 1} #\mathcal{M}_{J_\phi}(\phi)U^{n_w(\phi)} \cdot y,$$

extended linearly over $\mathbb{F}_2[U_w]$. The differential $\partial_{J_\phi}$ can be extended on $CF^\infty(\mathcal{H})$ and $CF^+(\mathcal{H})$ by tensoring with the identity map.

**Lemma 3.4 (OS08 Lemma 4.3).** For a generic path $J$, the map $\partial_{J_\phi}$ on $CF^\infty(\mathcal{H})$, where $\circ \in \{\times, +, -\}$, satisfies

$$\partial_{J_\phi} \circ \partial_{J_\phi} = 0.$$ 

For a disconnected multi-pointed 3-manifold $(Y, w) = (Y_1, w_1) \sqcup (Y_2, w_2)$, where $Y_i$ is connected for $i = 1, 2$, suppose $\mathcal{H}_i$ is an admissible multi-pointed Heegaard diagram of $Y_i$ and suppose $J_i$ are corresponding generic paths of almost complex structures. For $\circ \in \{\times, +, -\}$, let the chain complex associated to $(Y, w)$ be

$$(CF^\infty(\mathcal{H}_1 \sqcup \mathcal{H}_2), \partial_{J_\phi}) := (CF^\infty(\mathcal{H}_1), \partial_{J_{i_1}}) \otimes_{\mathbb{F}_2} (CF^\infty(\mathcal{H}_2), \partial_{J_{i_2}}).$$

**Remark 3.5.** In Zemke’s original construction [Zem19 Section 4.3], one should choose colors for basepoints and graphs to achieve the functoriality of the TQFT. For basepoints with the same color, the corresponding $U$-variables should be the same. In above notations, we implicitly choose different colors for all basepoints so that the $U$-variable for each basepoint is different. This is to obtain the following relation on the homology level

$$H(CF^\infty(\mathcal{H}_1 \sqcup \mathcal{H}_2), \partial_{J_\phi}) = H(CF^\infty(\mathcal{H}_1), \partial_{J_{i_1}}) \otimes_{\mathbb{F}_2} H(CF^\infty(\mathcal{H}_1), \partial_{J_{i_2}}).$$

Note that in the construction of [HMZ18 Zem18], the colors of all basepoints are the same and all $U$-variables are identified as $U$, so (3.1) should be a tensor product over $\mathbb{F}_2[U]$ rather than $\mathbb{F}_2$ and (3.2) does not hold in general.

**Remark 3.6.** Given a finite set of multi-pointed 3-manifolds and ribbon graph cobordisms, the chain complex $CF^-(\mathcal{G})$ is set to be $\mathbb{F}_2[U_w]$, where $U_w$ contains all $U$-variables associated to basepoints in the set. For any multi-pointed 3-manifold $(Y, w')$ with $w' \subset w$ that is in the given set, the actual chain complex in the TQFT should be

$$CF^-(Y, w') \otimes_{\mathbb{F}_2} \mathbb{F}_2[U \setminus U_w].$$

In the statements of results in this paper, we always have $w' = w$ for any multi-pointed 3-manifold $(Y, w')$. However, in the proof of those results (e.g. Lemma 3.35 and Theorem 3.30), we may have multi-pointed 3-manifold $(Y, w')$ such that $w' \neq w$; see Remark 3.36. Also, in the proof, the colors of basepoints may be different.

The chain homotopy type of $(CF^\infty(\mathcal{H}), \partial_{J_\phi})$ is independent of the choice of the admissible diagram $\mathcal{H}$ and the generic path $J_\phi$. Indeed, we have the following theorem about naturality.

**Theorem 3.7 (Zem19 Proposition 4.6), see also [OS04d, JZT18].** Suppose that $(Y, w)$ is a multi-pointed 3-manifold. To each (admissible) pairs $(\mathcal{H}, J)$ and $(\mathcal{H}', J')$, there is a well-defined map

$$\Psi_{(\mathcal{H}, J) \rightarrow (\mathcal{H}', J')} : (CF^-(\mathcal{H}), \partial_{J}) \rightarrow (CF^-(\mathcal{H}', \partial_{J})).$$
which is well-defined up to $\mathbb{F}_2[U_w]$-equivariant chain homotopy. Furthermore, the following holds.

(1) If $(\mathcal{H}, J)$, $(\mathcal{H}', J')$ and $(\mathcal{H}'', J'')$ are three pairs, then there is a chain homotopy equivalence

$$\Psi_{(\mathcal{H}, J) \rightarrow (\mathcal{H}'', J'')} \simeq \Psi_{(\mathcal{H}', J') \rightarrow (\mathcal{H}'', J'')} \circ \Psi_{(\mathcal{H}, J) \rightarrow (\mathcal{H}', J')}. $$

(2) $\Psi_{(\mathcal{H}, J) \rightarrow (\mathcal{H}, J)} \simeq \text{id}_{(CF^-(\mathcal{H}), \partial)}. $

Moreover, similar results hold for $CF^\infty$ and $CF^+$. 

**Convention.** If it is not mentioned, chain homotopy means $\mathbb{F}_2[U_w]$-equivariant chain homotopy.

Since all chain complexes discussed above can be decomposed into spin$^c$ structures (c.f. [OS04d Section 2.6]), we have the following definition.

**Definition 3.8.** Suppose $(Y, w)$ is a multi-pointed 3-manifold and $s \in \text{Spin}^c(Y)$. For $\circ \in \{\times, +, -\}$, define $CF^\circ(Y, w, s)$ to be the transitive system of chain complexes with canonical maps from Theorem 3.13 with respect to $s$, and define $HF^\circ(Y, w, s)$ to be the induced transitive system of homology groups.

For later use, we also define the completions of the chain complexes.

**Definition 3.9.** Let $\mathbb{F}_2[[U_w]]$ be the ring of formal power series of $U_w$. For $\circ \in \{\times, +, -\}$, define $CF^\circ(Y, w, s) := CF^\circ(Y, w, s) \otimes_{\mathbb{F}_2[U_w]} \mathbb{F}_2[[U_w]]$.

Let $HF^\circ(Y, w, s)$ be the induced homology groups.

**Convention.** When omitting the module structure, we have $CF^+(Y, w, s) = CF^+(Y, w, s)$. Hence we do not distinguish them.

The advantage of the completions is that we have the following proposition.

**Proposition 3.10 (MOS17 Section 2), see also [OS04a Lemma 2.3].** If $(Y, w)$ is a multi-pointed 3-manifold and $s \in \text{Spin}^c(Y)$ on each component is nontorsion, then $HF^\infty(Y, w, s) = 0$.

Then the boundary map in the following long exact sequence induces a canonical isomorphism between $HF^-(Y, w, s)$ and $HF^+(Y, w, s)$ for any nontorsion spin$^c$ structure $s$.

**Proposition 3.11.** From the short exact sequence

$$0 \rightarrow CF^-(Y, w, s) \rightarrow CF^\infty(Y, w, s) \rightarrow CF^+(Y, w, s) \rightarrow 0,$$

we have a long exact sequence

$$\cdots \rightarrow HF^-(Y, w, s) \rightarrow HF^\infty(Y, w, s) \rightarrow HF^+(Y, w, s) \rightarrow \cdots$$

**Definition 3.12.** Suppose $(Y, w)$ is a multi-pointed 3-manifold and $s \in \text{Spin}^c(Y)$ is a nontorsion spin$^c$ structure. We write

$$HF(Y, w, s) = HF_{\text{red}}(Y, w, s) := HF^+(Y, w, s) \cong HF^-(Y, w, s).$$

### 3.2. Cobordism maps for restricted graph cobordisms.

**Theorem 3.13 ([Zem19 Theorem A]).** Suppose $(W, \Gamma) : (Y_0, w_0) \rightarrow (Y_1, w_1)$ is a ribbon graph cobordism and $s \in \text{Spin}^c(W)$. Then there are two chain maps

$$F^A_{W, T, s}, F^B_{W, T, s} : CF^-(Y_0, w_0, s|_{Y_0}) \rightarrow CF^-(Y_1, w_1, s|_{Y_1}),$$

which are diffeomorphism invariants of $(W, \Gamma)$, up to $\mathbb{F}_2[U_w]$-equivariant chain homotopy.
Proposition 3.14 ([Zem19 Theorem C]). Suppose that \((W, \Gamma)\) is a ribbon graph cobordism which decomposes as a composition \((W, \Gamma) = (W_2, \Gamma_2) \cup (W_1, \Gamma_1)\). If \(s_1\) and \(s_2\) are spin\(^c\) structures on \(W_1\) and \(W_2\), respectively, then

\[
F^A_{W_2, \Gamma_2, s_2} \circ F^A_{W_1, \Gamma_1, s_1} = \sum_{s \in \text{Spin}^c(W)} F^A_{W, \Gamma, s}.
\]

A similar relation holds for \(F^B_{W, \Gamma, s}\).

Since we will only consider restricted graph cobordisms, the map \(F^A_{W, \Gamma, s}\) is chain homotopic to \(F^B_{W, \Gamma, s}\). Hence we write \(CF^-(W, \Gamma, s)\) for the chain map and \(HF^-(W, \Gamma, s)\) for the induced map on the homology group. If \(\Gamma\) and \(s\) are specified, we write \(CF^-(W)\) and \(HF^-(W)\) for simplicity, respectively. The chain maps on \(CF^\infty, CF^+, CF^-\) are obtained by tensoring with the identity maps, respectively. We use similar notations for these chain maps and the induced maps on homology groups. All maps are called cobordism maps.

For \(CF^-,\) the cobordism map is defined by the composition of the following maps.

- For 4-dimensional 1-, 2-, and 3-handle attachments away from the basepoints, we use the maps defined by Ozsváth and Szabó [OS06].
- For 4-dimensional 0- and 4-handle attachments, or equivalently adding and removing a copy of \(S^3\) with a single basepoint, respectively, we use the maps defined by the canonical isomorphism from the tensor product with \(CF^-(S^3, w_0) \cong \mathbb{F}_2[U_0]\).
- For a ribbon graph cobordism \((Y \times [0, 1], \Gamma)\), we project the graph into \(Y\) and use the graph action map defined in [Zem19 Section 7].

Remark 3.15. For 4-dimensional 1-, 2-, and 3-handle attachments, Ozsváth and Szabó’s original construction was for connected cobordisms between connected 3-manifolds. Zemke [Zem19 Section 8] extended the construction to cobordisms between possibly disconnected 3-manifolds. For 4-dimensional 0- and 4-handle attachments, the isomorphism is indeed

\[
CF^-(Y \cup S^3, w \cup \{w_0\}) \cong CF^-(Y, w) \otimes_{\mathbb{F}_2} CF^-(S^3, w_0) \cong CF^-(Y, w) \otimes_{\mathbb{F}_2} \mathbb{F}_2[U_0].
\]

The graph action map is obtained by the composition of maps associated to elementary graphs. The construction involves free-stabilization maps \(S^\pm_w\) [Zem19 Section 6] and relative homology maps \(A_\omega\) [Zem19 Section 5], where \(S^\pm_w\) correspond to adding or removing a basepoint \(w\) and \(A_\omega\) correspond to a path \(\omega\) between two basepoints. When considering restricted graph cobordisms, we only need maps associated to 1-, 2-, 3-handle attachments and free-stabilizations.

Definition 3.16. Suppose \(\mathcal{H} = (\Sigma, \alpha, \beta, w)\) is a multi-pointed Heegaard diagram for a multi-pointed 3-manifold \((Y, w)\). Let \(D \subset \Sigma \setminus (\alpha \cup \beta)\) be a small disk containing a new basepoint \(w_0 \in \Sigma \setminus (\alpha \cup \beta)\). Let \(\alpha_0\) and \(\beta_0\) be two simple closed curves on \(\Sigma\) bounding a disk containing \(w_0\) and \(|\alpha_0 \cap \beta_0| = 2\).

Suppose \(\theta^+\) and \(\theta^-\) are the higher and the lower graded intersection points, respectively. See Figure 4. Consider the Heegaard diagram \(\mathcal{H}' = (\Sigma, \alpha \cup \{\alpha_0\}, \beta \cup \{\beta_0\}, w \cup \{w_0\})\), where \(\alpha_0\) and \(\beta_0\) are in the region of a basepoint \(z \in w\).

For appropriately chosen almost complex structures, define the free-stabilization maps \(S^\pm_{w_0}\) by

\[
S^+_w(x) = x \times \theta^+,
\]

\[
S^-_{w_0}(x \times \theta^-) = x \text{ and } S^-_{w_0}(x \times \theta^+) = 0.
\]
Remark 3.17. If we collapse \( \partial D \) to a point \( p_0 \), we obtain a doubly-pointed diagram on \( S^2 \) with two curves. Hence \( \mathcal{H}' \) can be considered as the connected sum of \( \mathcal{H} \) and \((S^2, \alpha_0, \beta_0, \{w_0, p_0\})\) at the basepoint \( z \) in \( \mathcal{H} \) and the basepoint \( p_0 \) (c.f. [OS08 Section 6.1]).

Proposition 3.18 ([Zem19 Section 6 and Lemma 8.13]). The maps \( S_{w_0}^\pm \) in Definition 3.16 determine well-defined chain maps on the level of transitive systems of chain complexes

\[
S_{w_0}^+ : CF^-(Y, w) \rightarrow CF^-(Y, w \cup \{w_0\}),
\]

\[
S_{w_0}^- : CF^-(Y, w \cup \{w_0\}) \rightarrow CF^-(Y, w).
\]

Moreover, they have the following properites.

1. The maps \( S_{w_0}^\pm \) commute with maps associated to 1-, 2-, and 3-handle attachments.
2. For \( \sigma_1, \sigma_2 \in \{+, -, \}, \) we have \( S_{w_1}^{\sigma_1} S_{w_2}^{\sigma_2} = S_{w_2}^{\sigma_2} S_{w_1}^{\sigma_1} \).

Remark 3.19. The free-stabilization maps can be regarded as restricted graph cobordisms with \( W = Y \times [0,1] \). The graphs are shown in Figure 5. Alternatively, we can regard them as compositions of maps associated to handle attachments. The map \( S_{w_2}^+ \) is obtained by first attaching a 0-handle with an arc whose one endpoint is on the boundary, and the other is in the interior, and then attaching a product 1-handle away from basepoints; see Figure 5. The map \( S_{w_2}^- \) is obtained by first attaching a 3-handle and then a 4-handle with an arc similarly.

Figure 4. Free-stabilization in a small disk \( D \).

Figure 5. Restricted graph cobordisms related to free-stabilization maps.
Convention. All illustrations of cobordisms are from top to bottom.

We can calculate the effect of free-stabilization maps on the homology explicitly.

**Proposition 3.20** ([OS08] Proposition 6.5). Consider the construction in Definition 3.16. For suitable choices of almost complex structures, the chain complex $CF^-(\mathcal{H}')$ is identified with the mapping cone of the following map

$$CF^-(\mathcal{H}) \otimes_{F_2} F_2[U_0](\theta^-) \xrightarrow{U_0-U_1} CF^-(\mathcal{H}) \otimes_{F_2} F_2[U_0](\theta^+),$$

where $U_1$ corresponds to the basepoint in the original diagram $\mathcal{H}$ for the connected sum construction in Remark 3.17.

**Corollary 3.21.** If $U_0 \neq U_1$ in Proposition 3.20, i.e. the colors of corresponding basepoints are different (c.f. Remark 3.5), then the map $S^0\wedge_{Pt8}$ induces isomorphisms on $HF^\circ$ and $HF^\circ$ for $\circ \in \{+,-\}$, and the map $S^0\wedge_{Pt8}$ induces zero maps on all versions of Heegaard Floer homology.

**Proof.** The arguments for $\circ \in \{+, -\}$ follows directly from Definition 3.16, Proposition 3.20 and definitions of Heegaard Floer homology groups. For $\circ = +$, note that the free-stabilization maps are compatible with the long exact sequence in Proposition 3.11. Hence the behaviors of maps for $\circ \in \{+, -\}$ imply the behavior for $\circ = +$. \qed

The following proposition implies the choice of the basepoints is not important.

**Proposition 3.22** ([Zem19] Corollary 14.19 and Corollary F). Suppose $(Y, w)$ is a multi-pointed 3-manifold and $w_1 \in w$. Then the $\pi_1(Y,w_1)$ action on $HF^-(Y,w)$ is always the identity map.

Suppose $(Y_1, w_1)$ and $(Y_2, w_2)$ are two multi-pointed 3-manifolds with $|w_1| = |w_2|$. Suppose $W$ is a cobordism from $Y_1$ to $Y_2$ and $\Gamma \subset W$ is a collection of paths connecting $w_1$ and $w_2$. Then the cobordism map $HF^-(W, \Gamma)$ is independent of the choice of $\Gamma$. Moreover, if $W = Y \times I$, then $HF^-(W, \Gamma)$ is an isomorphism.

Similar results also hold for $HF^\circ$, $HF^+, HF^-, HF^\circ$.

From Corollary 3.21 and Proposition 3.22, we can define a transitive system of groups based on different choices of basepoints.

**Definition 3.23.** Suppose $Y$ is a closed, oriented 3-manifold and $w_1, w_2 \subset Y$ are two collections of basepoints in $Y$. Let $w'_1 = w_1 \setminus w_2$ and $w'_2 = w_2 \setminus w_1$. For $\circ \in \{+, +, -\}$, define transition maps associated to $(w_1, w_2)$ as

$$\Psi_{w_1 \to w_2}^\circ := \prod_{w \in w'_1} (S_w^+)^{-1} \circ \prod_{w \in w'_2} S_w^+$$

on $HF^\circ$ and $HF^\circ$.

where the products mean compositions. The order of maps is not important by the following lemma.

**Lemma 3.24.** Suppose $Y$ is a closed, oriented 3-manifold and $w_1, w_2, w_3 \subset Y$ are three collections of basepoints in $Y$. Suppose $w$ is a basepoint in $Y$ that is not in $w_i$ for $i = 1, 2$. Then the following holds for transition maps.

1. $\Psi_{w_1 \to w_2}^\circ$ is well-defined for $i, j \in \{1, 2, 3\}$, i.e., the composition is independent of the order of maps.
2. $\Psi_{w_i \to w_j}^\circ$ is an isomorphism for $i, j \in \{1, 2, 3\}$.
3. $\Psi_{w_i \to w_i}^\circ = \text{id}$ for $i = 1, 2, 3$.
4. $\Psi_{w_2 \to w_3}^\circ \circ \Psi_{w_1 \to w_2}^\circ = \Psi_{w_1 \to w_3}^\circ$.
5. $\Psi_{w_1 \cup \{w\} \to w_2 \cup \{w\}}^\circ \circ S_w^+ = S_w^+ \circ \Psi_{w_1 \to w_2}^\circ$. 

(6) $\Psi_{w_1 \rightarrow w_2} \circ S_w^- = S_w^- \circ \Psi_{w_1 \cup \{w\} \rightarrow w_2 \cup \{w\}}$.

Proof. Terms (1), (4), (5) and (6) follow from term (2) of Proposition 3.18. Note that maps in terms (5) are both isomorphisms and the maps in term (6) are both zero maps. Term (3) is trivial from the definition. Term (2) follows from Corollary 3.21.

Lemma 3.25. Suppose $Y_1$ and $Y_2$ are closed, oriented 3-manifolds and $w_1, w_2 \subset Y_1, w_3, w_4 \subset Y_2$ are collections of basepoints. Suppose $W$ is a cobordism from $Y_1$ to $Y_2$ that is induced by a composition of 1-, 2-, 3-handle attachments away from all basepoints. Let $\Gamma_1$ and $\Gamma_2$ be induced graphs in $W$ with

$\Gamma_1 \cap Y_1 = w_1, \Gamma_1 \cap Y_2 = w_3, \Gamma_2 \cap Y_1 = w_2, \text{ and } \Gamma_2 \cap Y_2 = w_4$.

Then we have a commutative diagram

$$
\begin{array}{ccc}
\text{HF}^{-}(Y_1, w_1) & \xrightarrow{\text{HF}^{-}(W, \Gamma_1)} & \text{HF}^{-}(Y_2, w_3) \\
\downarrow & & \downarrow \\
\text{HF}^{-}(Y_1, w_2) & \xrightarrow{\text{HF}^{-}(W, \Gamma_2)} & \text{HF}^{-}(Y_2, w_4)
\end{array}
$$

Similar commutative diagrams hold for $\text{HF}^{-}$ and $\text{HF}^{+}$.

Proof. This follows from term (1) of Proposition 3.18.

Theorem 3.26. Suppose $Y$ is a closed, oriented 3-manifold. Then groups $\text{HF}^{-}(Y, w)$ for all $w \subset Y$ and transition maps $\Psi_{w_1 \rightarrow w_2}$ for all $w_1, w_2 \subset Y$ form a transitive system, which is denoted by $\text{HF}^{-}(Y)$. Moreover, suppose $(W, \Gamma)$ is a restricted graph cobordism from $(Y_1, w_1)$ to $(Y_2, w_2)$. Then $\text{HF}^{-}(W, \Gamma)$ induces a well-defined map from $\text{HF}^{-}(Y_1)$ to $\text{HF}^{-}(Y_2)$, which is independent of the choice of the restricted graph $\Gamma$ and denoted by $\text{HF}^{-}(W)$.

Similar arguments hold for other versions of Heegaard Floer homology groups.

Proof. The well-definedness of $\text{HF}^{-}(Y)$ and $\text{HF}^{-}(W, \Gamma)$ follows from Lemma 3.24 and Lemma 3.25. Note that the restricted graph cobordism is a composition of maps associated to 1-, 2-, 3-handle attachments and free-stabilizations. By Lemma 3.21, free-stabilizations maps are either isomorphisms or zero maps. Then the independence of $\Gamma$ follows from Proposition 3.22 and above lemmas. The proofs for other versions of Heegaard Floer homology groups are similar.

Remark 3.27. Groups and maps in Theorem 3.26 also split into spin$^c$ structures. Suppose $s \in \text{Spin}^c(W)$ is a nontorsion spin$^c$ structure which restricts to nontorsion spin$^c$ structure $s_i$ on $Y_i$ for $i = 1, 2$. Then $\text{HF}^{-}(Y_i, s_i)$ and $\text{HF}^{+}(Y_i, s_i)$ are canonically identified by the boundary map in Proposition 3.11. Moreover, the maps $\text{HF}^{-}(W, s)$ and $\text{HF}^{+}(W, s)$ are the same under this identification. We write the map as $\text{HF}(W, s)$.

3.3. Floer’s excision theorem.

Note that the proofs of Theorem 2.13 and Theorem 2.24 (c.f. [BS13, L13]) both involve Floer’s excision theorem in an essential way. In this subsection, we follow Kronheimer and Mrowka’s idea in [KM10b, Section 3] to prove an excision theorem for Heegaard Floer theory. The proof in [KM10b, Section 3] depends essentially on the TQFT properties and Axiom (A1), so it works for a general TQFT satisfying Axiom (A1). Though for Heegaard Floer theory, we need to modify the proof to fit the settings of multi-basepoints 3-manifolds and ribbon graph cobordisms.

Let $Y$ be a closed, oriented 3-manifold, of either one or two components. In the latter case, let $Y_1$ and $Y_2$ be two components of $Y$. Let $\Sigma_1$ and $\Sigma_2$ be two closed, connected, oriented surfaces in
Y with \( g(\Sigma_i) = g(\Sigma_2) \). If \( Y \) has two components, suppose \( \Sigma_i \) is a non-separating surface in \( Y \) for \( i = 1, 2 \). If \( Y \) is connected, suppose \( \Sigma_1 \) and \( \Sigma_2 \) represent independent homology classes. In either case, let \( F = \Sigma_1 \cup \Sigma_2 \). Let \( h \) be an orientation-preserving diffeomorphism from \( \Sigma_1 \) to \( \Sigma_2 \).

We construct a new manifold \( \tilde{Y} \) as follows. Let \( \tilde{Y}' \) be obtained from \( Y \) by cutting along \( \Sigma \). Then \( \partial \tilde{Y}' = \Sigma_1 \cup (-\Sigma_1) \cup \Sigma_2 \cup (-\Sigma_2) \).

If \( Y \) has two components, then we have \( \tilde{Y}' = \tilde{Y}'_1 \cup \tilde{Y}'_2 \), where \( \tilde{Y}'_i \) is obtained from \( Y_i \) by cutting along \( \Sigma_i \) for \( i = 1, 2 \). Let \( \tilde{Y} \) be obtained from \( \tilde{Y}' \) by gluing the boundary component \( \Sigma_1 \) to the boundary component \( -\Sigma_2 \) and gluing \( \Sigma_2 \) to \( -\Sigma_1 \), using the diffeomorphism of \( h \) in both cases; see Figure 6 for the case that \( Y \) has two components.

\[\begin{align*}
\text{Figure 6. Construction of } \tilde{Y}.
\end{align*}\]

In either case, \( \tilde{Y} \) is connected. Let \( \tilde{\Sigma}_i \) be the image of \( \Sigma_i \) in \( \tilde{Y} \) for \( i = 1, 2 \) and let \( \tilde{F} = \tilde{\Sigma}_1 \cup \tilde{\Sigma}_2 \).

**Definition 3.28.** Suppose \( Y \) is a closed, oriented 3-manifold and \( F \subset Y \) is a closed, oriented surface. Let \( F_i \) for \( i = 1, \ldots, m \) be the components of \( F \). Suppose further that \( g(F_i) \geq 2 \) and any component of \( Y \) contains at least one component of \( F \). Let \( \text{Spin}^c(Y|F) \) denote the set of \( \text{spin}^c \) structures \( s \in \text{Spin}^c(Y) \) satisfying

\[
\langle c_1(s), F_i \rangle = 2g(F_i) - 2 \text{ for any } F_i.
\]

Define

\[
HF(Y|F) := \bigoplus_{s \in \text{Spin}^c(Y|F)} HF(Y, s).
\]

Suppose \( (W, \Gamma) \) is a restricted graph cobordism and \( G \subset W \) is a closed, oriented surface. Let \( G_i \) for \( i = 1, \ldots, n \) be components of \( G \). Suppose further that \( g(G_i) \geq 2 \) and any component of \( W \) contains at least one component of \( G \). Let \( \text{Spin}^c(W|G) \) denote the set of \( \text{spin}^c \) structures \( s \in \text{Spin}^c(W) \) satisfying similar conditions in (3.3) by replacing \( F_i \) by \( G_i \). Define

\[
HF^-(W, \Gamma|G) := \sum_{s \in \text{Spin}^c(W|G)} HF^-(W, \Gamma, s).
\]

Let \( HF^+(W, \Gamma|G), \ HF^-(W, \Gamma|G) \) and \( HF(W, \Gamma|G) \) be defined similarly. We also denote the corresponding map on the chain level by replacing \( HF \) by \( CF \).

**Remark 3.29.** All \( \text{spin}^c \) structures in \( \text{Spin}^c(Y|F) \) are nontorsion, so \( HF(Y, s) \) is well-defined.

The following is the main theorem of this subsection.
Theorem 3.30 (Floer’s excision theorem). Consider \( Y \) and \( \tilde{Y} \) constructed as above. If \( g(\Sigma_1) = g(\Sigma_2) \geq 2 \), then there is an isomorphism

\[
HF(Y|F) \cong HF(\tilde{Y}|\tilde{F}).
\]

Moreover, this isomorphism and its inverse are induced by restricted graph cobordisms.

Before proving the main theorem, we introduce some lemmas analogous to results in monopole theory (c.f. [KM10b, Lemma 2.2, Proposition 2.5 and Lemma 4.7])

Lemma 3.31 ([Lek13, Theorem 16 and Corollary 17], see also [OS04a, Theorem 5.2]). Let \( Y \to S^1 \) be a fibred 3-manifold whose fibre \( F \) is a closed, connected, oriented surface with \( g = g(F) \geq 2 \). Then \( CF^-(Y|F) \) is chain homotopic to the chain complex

\[
0 \to \mathbb{F}_2[U_0] \langle x \rangle \xrightarrow{U_0} \mathbb{F}_2[U_0] \langle y \rangle \to 0.
\]

Thus, there is a unique \( s_0 \in \text{Spin}^c(Y|R) \) so that \( HF(Y, s_0) \neq 0 \) and we have

\[
HF(Y|F) = HF(Y, s_0) \cong \mathbb{F}_2.
\]

Remark 3.32. Indeed, for \( Y \) in Lemma 3.31, we can construct an admissible Heegaard diagram \( \mathcal{H} \) for the singly-pointed 3-manifold \( (Y, w) \) so that \( CF^-(\mathcal{H}, s_0) \) is generated by \( 8g \) generators \( x_1, \ldots, x_{4g}, y_1, \ldots, y_{4g} \) and

\[
\partial x_1 = U_0 y_1, \quad \partial x_j = y_j, \quad \text{and} \quad \partial y_k = 0 \text{ for } j > 1, k \geq 1.
\]

Lemma 3.33. Suppose \( Y = \Sigma \times S^1 \) such that \( \Sigma = \Sigma \times \{1\} \subset Y \) is a closed, connected, oriented surface with \( g(\Sigma) \geq 2 \). Suppose \( w_0 \in S^3 \) and \( w \in Y \) are basepoints. Let \( W \) be obtained from \( \Sigma \times D^2 \) by removing a 4-ball, considered as a cobordism from \( S^3 \) to \( Y \). Let \( \Gamma \subset W \) be any path connecting \( w_0 \) to \( w \). Then the map

\[
HF^-(W, \Gamma|\Sigma) : \mathbb{F}_2[U_0] \cong HF^{-}(S^3, w_0) \to HF(Y, w|\Sigma) \cong \mathbb{F}_2
\]

is nonzero.

Figure 7. Nontrivial cobordism map from composition.
Proof. Suppose $P$ is 2-dimensional pair of pants as shown in Figure 7. Consider $W' = \Sigma \times P$ as a cobordism from $Y_1 \sqcup Y_2$ to $Y_3$, where $Y_i \cong Y$ for $i = 1, 2, 3$. Suppose $w'$ is another basepoint in $Y$. Let $w_i$ and $w'_i$ be images of $w$ and $w'$ in $Y_i$ for $i = 1, 2, 3$. Let $\Gamma' \subset W'$ be a collection of two paths $\gamma_1$ and $\gamma_2$, where $\gamma_1$ connects $w'_1$ to $w'_3$ and $\gamma_2$ connects $w_2$ to $w_3$.

Let $(W_1, \Gamma_1) = (Y_1 \times I, w' \times I)$ be the product cobordism. Suppose $\Sigma_i \subset Y_i$ is the image of $\Sigma \subset Y$ for $i = 1, 2, 3$. Consider the composition of the cobordism maps

$$HF^-(W', \Gamma'|\Sigma_1 \cup \Sigma_2 \cup \Sigma_3) : HF(Y_1, {w'_1}|\Sigma_1) \otimes_{F_2} HF^-(S^3, w_0) \to HF(Y_3, \{w_3, w'_3\}|\Sigma_3).$$

After filling the $S^3$ component by a 4-ball, or equivalently composing it with the map associated to a 0-handle attachment, we obtain the free-stabilization map $S^3_w$ (c.f. Remark 3.19). By Corollary 3.21 the resulting map is an isomorphism

$$HF(Y_1, w'_1|\Sigma_1) \cong HF(Y_3, \{w_3, w'_3\}|\Sigma_3).$$

Since

$$HF^-(W_1 \sqcup W, \Gamma_1 \sqcup \Gamma|\Sigma_1 \cup \Sigma_2) = HF^-(W_1, \Gamma_1|\Sigma_1) \otimes_{F_2} HF^-(W, \Gamma|\Sigma_2),$$

and $HF^-(W_1|\Sigma_1)$ is the identity map, we know $HF^-(W|\Sigma_2)$ is nonzero.

Corollary 3.34. On the chain level of (3.3), the cobordism map $CF^-(W, \Gamma|\Sigma)$ sends the generator of $CF^-(S^3, w_0) \cong F_2[U_0]$ to the generator of second copy of $F_2[U_0]$ in (3.4).

Proof. The map in the statement is the only $F_2[U_0]$-equivariant chain map that induces a nonzero map on the homology. □

The proof of the following lemma is due to Ian Zemke.

Lemma 3.35. Let $Y = \Sigma \times S^1$ and let $W_1 \cong Y \times I$ is a cobordism from $\emptyset$ to $Y \sqcup (-Y)$. Let $w_1, w_2 \in Y, w'_1, w'_2 \in W_1$ and let $\Gamma_1 \subset W_1$ consist of two paths whose endpoints are $w_1$ and $w'_1$, for $i = 1, 2$, as shown in the left subfigure of Figure 8. Let $W_2 \cong \Sigma \times D^2 \sqcup (-\Sigma \times D^2)$ be another cobordism from $\emptyset$ to $Y \sqcup (-Y)$ and let $\Gamma_2 \subset W_2$ be obtained from two copies of the cobordism in Lemma 3.33 associated to $\Sigma$ and $-\Sigma$ by filling the $S^3$ components by 4-balls (c.f. Remark 3.19), as shown in the right subfigure of Figure 8. Then we have

$$(3.6) CF^-(W_1, \Gamma_1|\Sigma \sqcup (-\Sigma)) \cong CF^-(W_2, \Gamma_2|\Sigma \sqcup (-\Sigma)) : CF^-(\emptyset) \to CF^-(Y \sqcup (-Y), \{w_1, w_2\}|\Sigma \sqcup (-\Sigma)).$$

Proof. Set $R = F_2[U_1, U_2]$. By Remark 3.5 we implicitly choose $w_1$ and $w_2$ to have different colors and then

$$CF^-(Y \sqcup (-Y), \{w_1, w_2\}|\Sigma \sqcup (-\Sigma)) := CF^-(Y|\Sigma) \otimes_{F_2} CF^-(Y, -\Sigma).$$

By Remark 3.6 we have $CF^-(\emptyset) = R$. By TQFT property in [Zem19], we have a canonical chain isomorphism

$$CF^-(Y, w_2|-\Sigma) \cong CF^-(Y, w_2|\Sigma)^\vee := \text{Hom}_R(CF^-(Y, w_2|\Sigma), R).$$
Then by Lemma 3.31, we have

$$\text{CF}^{-}(Y \sqcup (-Y), \{w_1, w_2\}|\Sigma \sqcup (-\Sigma)) \cong \mathcal{R}\langle x \otimes y^\vee \rangle \xrightarrow{U_1} \mathcal{R}\langle x \otimes x^\vee \rangle$$

(3.7)

where $x^\vee$ and $y^\vee$ are duals of $x$ and $y$, respectively. By Corollary 3.34, we know $\text{CF}^{-}(W_2, \Gamma_2|\Sigma \sqcup (-\Sigma))$ sends the generator of $\text{CF}^{-}(\emptyset)$ to $y \otimes x^\vee$ in (3.7).

By Proposition 3.14, we compute $\text{CF}^{-}(W_1, \Gamma_1|\Sigma \sqcup (-\Sigma))$ by decomposing $(W_1, \Gamma_1)$ into three parts $(W_i^1, \Gamma_i^1): (Y_{i-1}, w_{i-1}) \rightarrow (Y_i, w_i)$ for $i = 1, 2, 3$ as shown in the middle subfigure of Figure 8.

Note that $(Y_0, w_0) = \emptyset$. Let $F$ be images of $\Sigma \sqcup (-\Sigma)$.

First, we compute $\text{CF}^{-}(W_1, \Gamma_1^1|F)$. Since the two basepoints in $w_1$ have the same color (also the same as $w_2$), we have

$$\text{CF}^{-}(Y_1, w_1|F) \cong \mathcal{R}\langle x \otimes y^\vee \rangle \xrightarrow{U_2} \mathcal{R}\langle x \otimes x^\vee \rangle$$

(3.8)

From Zemke’s calculation [Zem18, Theorem 1.7], the cobordism map $\text{CF}^{-}(W_1^1, \Gamma_1^1|F)$ is the canonical cotrace map, i.e., it sends the generator of $\text{CF}^{-}(\emptyset)$ to $x \otimes x^\vee + y \otimes y^\vee$.

Remark 3.36. Though we only have one color in $w_1$, we use $\mathcal{R}$ rather than $\mathcal{F}_2[U_2]$ in (3.8) to achieve the functoriality (c.f. Remark 3.6). Thus, when applying Proposition 3.20 in the following computation, we do not need to add another U-variable.

Second, we compute $\text{CF}^{-}(W_2^1, \Gamma_2^1|F)$. Note that the left component of $(W_2^1, \Gamma_2^1)$ corresponds to the free-stabilization map $S^+_{w_1}$ and the right component is just the identity map. By Proposition
the chain complex $CF^-(Y_2, w_2|F)$ is chain homotopic to the mapping cone of (3.9)

$$
\begin{align*}
\mathcal{R}\langle x \otimes y^\gamma \otimes \theta^- \rangle & \xrightarrow{U_2} \mathcal{R}\langle x \otimes x^\gamma \otimes \theta^- \rangle \\
U_2 & \quad U_2 \\
\mathcal{R}\langle y \otimes y^\gamma \otimes \theta^- \rangle & \xrightarrow{U_2} \mathcal{R}\langle y \otimes x^\gamma \otimes \theta^- \rangle
\end{align*}
$$

(3.10)

$$
\begin{align*}
\mathcal{R}\langle x \otimes y^\gamma \otimes \theta^+ \rangle & \xrightarrow{U_2} \mathcal{R}\langle x \otimes x^\gamma \otimes \theta^+ \rangle \\
U_2 & \quad U_2 \\
\mathcal{R}\langle y \otimes y^\gamma \otimes \theta^+ \rangle & \xrightarrow{U_2} \mathcal{R}\langle y \otimes x^\gamma \otimes \theta^+ \rangle
\end{align*}
$$

where $u \otimes v \otimes \theta^\pm$ for $u \in \{x, x^\gamma\}, y \in \{y, y^\gamma\}$ represents $(u \times \theta^\pm) \otimes v$. Then $CF^-(W_1^2, \Gamma_1^2|F)$ sends any generator $u \otimes v$ to $u \otimes v \otimes \theta^+$ in (3.9).

Third, we compute $CF^-(W_3^1, \Gamma_1^1|F)$. Note that the left component of $(W_3^1, \Gamma_1^1)$ corresponds to the free-stabilization map $S_{w_2}$ and the right component is just the identity map. Also by Proposition 3.20 the chain complex $CF^-(Y_2, w_2|F)$ is chain homotopic to the mapping cone of (3.10)

$$
\begin{align*}
\mathcal{R}\langle x \otimes y^\gamma \otimes \theta^- \rangle & \xrightarrow{U_1} \mathcal{R}\langle x \otimes x^\gamma \otimes \theta^- \rangle \\
U_2 & \quad U_2 \\
\mathcal{R}\langle y \otimes y^\gamma \otimes \theta^- \rangle & \xrightarrow{U_1} \mathcal{R}\langle y \otimes x^\gamma \otimes \theta^- \rangle
\end{align*}
$$

Then $CF^-(W_3^1, \Gamma_1^1|F)$ sends $u \otimes v \otimes \theta^-$ to $u \otimes v$ in (3.7) and sends $u \otimes v \otimes \theta^+$ to 0 for $u \in \{x, x^\gamma\}, y \in \{y, y^\gamma\}$.

To compute the composition, we need to find the explicit chain homotopy between above two mapping cones (3.9) and (3.10), which is calculated by Zemke [Zem19, Theorem 14.1]. Since we only care about the image of $CF^-(\emptyset)$, we only need to calculate the image of $* \text{ map}$ in [Zem19, (14.3)] (from the target in (3.9) to the source in (3.10))

$$
\sum_{i, j \geq 0} U_w^i U_w^j (\bar{\partial}_{i+j+1}) U_w U_{w'}
\begin{pmatrix}
\Psi_{\alpha \rightarrow \alpha'} U_w - U_{w'} \\
\Psi_{\beta \rightarrow \beta'} U_w - U_{w'}
\end{pmatrix}
$$

(3.11)

for the element

$$
x \otimes x^\gamma \otimes \theta^+ + y \otimes y^\gamma \otimes \theta^+
$$

(3.12) in (3.9). In (3.11), we have $z \in Y_1$ for the connected sum construction in Remark 3.17 $w = w_2, w' = w_1, U_w = U_2, U_{w'} = U_1$ and $\alpha', \beta'$ being small isotopies of $\alpha, \beta$, respectively. The differential $\partial_k$ comes from

$$
\partial = \sum_{k \in \mathbb{N}} U_z^k \partial_k,
$$

(3.13)

where $\partial$ is the differential in

$$
\begin{align*}
CF^-(Y_1, \{z, w_2\} \cup (\Sigma)) & \cong \mathcal{R}\langle x \otimes y^\gamma \rangle \xrightarrow{U_z} \mathcal{R}\langle x \otimes x^\gamma \rangle \\
U_2 & \quad U_2 \\
\mathcal{R}\langle y \otimes y^\gamma \rangle & \xrightarrow{U_z} \mathcal{R}\langle y \otimes x^\gamma \rangle
\end{align*}
$$

(3.14)

For a map $f$, the notation $(f)^{U_z \rightarrow U_w}$ means we replace $U_z$ by $U_w$ in the image of $f$ and the notation $(f)_{U_w}$ means tensoring $f$ with the identity map in $\mathbb{F}_2[U_w]$. 
Since the element \(3.12\) has no \(U\)-power, the transition maps \((\Psi_{\alpha \to \alpha'})^\theta_{\alpha \to \alpha'}\) can be regarded as identity maps. By (3.13) and (3.14), we know \(\partial_k = 0\) for \(k \geq 1\) and \(\partial_1\) sends \(x \otimes x'\) to 0 and sends \(y \otimes y'\) to \(y \otimes x'\). Hence the \(*\) map (3.11) sends the element \(3.12\) to \(y \otimes x' \otimes \theta^*\) in (3.10).

Thus, by composing three cobordism maps and up to chain homotopy, we show that \(CF^-(W_1, \Gamma_1|\Sigma \square (-\Sigma))\) also sends the generator of \(CF^-(\emptyset) = \mathcal{R}\) to \(y \otimes x'\) in (3.7).

Now we start to prove the main theorem of this subsection. The basic idea is from Kronheimer and Mrowka [KM10b, Section 3.2], which originally came from Floer’s work [Flo90a], where he dealt with the excision theorem in instanton theory for the genus one case.

**Proof of Theorem 3.30.** **Step 1.** We construct a cobordism \(W\) from \(\tilde{Y}\) to \(Y\) and a cobordism \(\tilde{W}\) from \(Y\) to \(\tilde{Y}\).

Recall that \(Y'\) is obtained from \(Y\) by cutting along \(\Sigma_1\) and \(\Sigma_2\) and we have

\[\partial Y' = \Sigma_1 \cup (-\Sigma_1) \cup \Sigma_2 \cup (-\Sigma_2).\]

Suppose \(P_1\) is a saddle surface, which can be regarded as a submanifold of a pair of pants with one boundary component on the top and two boundary components at the bottom; see the left subfigure of Figure 9. Suppose

\[\partial P_1 = \lambda_1 \cup \lambda_2 \cup \mu_1 \cup \mu_2 \cup \eta_1,1 \cup \eta_{1,2} \cup \eta_{2,1} \cup \eta_{2,2},\]

where \(\lambda_1\) and \(\lambda_2\) are two arcs in the top boundary component of the pair of pants, \(\mu_1\) and \(\mu_2\) are two arcs in the bottom boundary components of the pair of pants, and \(\eta_{i,j}\) is the arc connecting \(\lambda_i\) and \(\mu_j\) for \(i, j \in \{1, 2\}\).

Suppose \(\Sigma = \Sigma_1 \cong \Sigma_2\). Note that we have fixed a diffeomorphism \(h\) from \(\Sigma_1\) to \(\Sigma_2\). Suppose \(h'\) is an orientation-preserving diffeomorphism from \(\Sigma\) to \(\Sigma_1\). Let \(W\) be the union

\[P_1 \times \Sigma \cup Y' \times I,\]

where \(\eta_{1,1} \times \Sigma\) is glued to \(\Sigma_1 \times I\), \(\eta_{2,1} \times \Sigma\) is glued to \(-\Sigma_1 \times I\), \(\eta_{2,2} \times \Sigma\) is glued to \(\Sigma_2 \times I\), and \(\eta_{1,2} \times \Sigma\) is glued to \(-\Sigma_2 \times I\), using \(h'\) and \(h \circ h'\), respectively. Figure 9 illustrates the case that \(Y'\) has two components \(Y'_1\) and \(Y'_2\). By the construction of \(\tilde{Y}\), the resulting manifold \(W\) is a cobordism from \(\tilde{Y}\) to \(Y\).

The cobordism \(\tilde{W}\) is constructed similarly. Let \(P_2\) be another saddle surface and let \(\tilde{W}\) be obtained by gluing \(P_2 \times \Sigma\) and \(Y' \times I\) as shown in the right subfigure of Figure 9.

**Step 2.** For some restricted graph \(\Gamma_A\) and some surface \(G_A\) in \(W_A = \tilde{W} \cup \tilde{Y}\), we show the cobordism map

\[HF(W_A, \Gamma_A|G_A) := HF^+(W_A, \Gamma_A|G_A) = HF^-(W_A, \Gamma_A|G_A)\]

induces the identity map on

\[HF(Y|F) := HF^+(Y|F) = HF^-(Y|F).\]

We prove for the case that \(Y\) has two components \(Y_1\) and \(Y_2\). The proof for the case that \(Y\) is connected is similar. For \(i = 1, 2\), let \(w_i \in Y_i\) be basepoints and let \(\Gamma_A \subset W_A\) consist of paths connecting basepoints \(w_i\) in different ends of \(W_A\); see the left subfigure of Figure 10. Suppose \(W_A'\) is diffeomorphic to \(W_A\) but drawn in a different position and suppose \(\Gamma_A' \subset W_A'\) is obtained from \(\Gamma_A\) by adding an arc to each path and choosing any ordering for the vertex with valence 3; see the middle subfigure of Figure 10. By [Zem19] Section 11.2, the ribbon graph cobordisms \((W_A, \Gamma_A)\) and \((W_A', \Gamma_A')\) induce the same cobordism map. Suppose \(Y_A \cong \Sigma \times S^1 \subset W_A\) is the manifold in the
neck of $W_A'$. We know a neighborhood $N(Y_A)$ is diffeomorphic to $Y_0 \times I$. Let $G_A$ consist of images of $\Sigma$ in $\partial W_A$ and $\partial N(Y_0)$.

By Proposition 3.14 we can decompose $(W_A', \Gamma_A')$ into two parts as shown in the left subfigure of Figure 11 and compute $\text{HF}(W_A, \Gamma_A|G_A)$ by composition of two cobordism maps. The first part has three components corresponding to $Y_1 \times I, N(Y_A)$, and $Y_2 \times I$, respectively. By Lemma 3.35 we can replace the component corresponding to $N(Y_A)$ by two components corresponding to $\Sigma \times D^2 \sqcup (-\Sigma \times D^2)$ in the right subfigure of Figure 8. Then we know the cobordism map $\text{HF}(W_A, \Gamma_A|G_A)$ is the same as $\text{HF}(W_A', \Gamma''|G_A)$, where $(W_A', \Gamma'')$ is the ribbon graph cobordism in the right subfigure of Figure 11. By [Zem19, Section 11.2], we can remove the arcs of $\Gamma''$ in the interior of the cobordism $W_A''$. Then we know $\text{HF}(W_A', \Gamma''|G_A)$ is the identity map because

$$(W_A', \Gamma''_A) \cong (Y_1 \sqcup Y_2) \times I, (w_1 \sqcup w_2) \times I).$$

Thus, the cobordism map $\text{HF}(W_A, \Gamma|G_A)$ is the identity map.

**Step 3.** For some restricted graph $\Gamma_B$ and some surface $G_B$ in $W_B = W \cup_Y \tilde{W}$, we show the cobordism map

$$\text{HF}(W_B, \Gamma_B|G_B) : = \text{HF}^+(W_B, \Gamma_B|G_B) = \text{HF}^-(W_B, \Gamma_B|G_B)$$
induces the identity map on
\[ \text{HF}(\tilde{Y}|\tilde{F}) := \text{HF}^+(\tilde{Y}|\tilde{F}) \cong \text{HF}^-(\tilde{Y}|\tilde{F}). \]

We prove for the case that \( Y \) has two components \( Y_1 \) and \( Y_2 \). The proof for the case that \( Y \) is connected is similar. The ribbon graph cobordism \((W_B, \Gamma_B)\) is shown in the left subfigure of Figure 12 and suppose endpoints of \( \Gamma_B \) correspond to \( w_1' \) and \( w_2' \) in \( \tilde{Y} \). The proof is essentially the same as that in Step 2. We first change the position of \( W_B \) and add two arcs to \( \Gamma_B \) to obtain \((W_B', \Gamma_B')\), as shown in the middle subfigure of Figure 12. Second, we choose \( Y_B \) in the neck of \( W_B' \) and set \( G_B \) to be images of \( \Sigma \) in \( \partial W_B' \) and \( \partial N(Y_B) \). Third, we replace \( N(Y_B) \) by \( \Sigma \times D^2 \sqcup (-\Sigma \times D^2) \) via Lemma 3.35 to obtain \((W_B'', \Gamma_B'')\), as shown in the right subfigure of Figure 12. Finally we remove arcs in the interior of the cobordism and show it is the identity map because
\[ (W_B'', \Gamma_B'') \cong (\tilde{Y} \times I, (w_1' \sqcup w_2') \times I). \]
Finally, we know Step 2 and Step 3 imply

$$HF(Y|F) \cong HF(\hat{Y}|\hat{F})$$

via cobordism maps associated to ribbon graph cobordisms

$$(W, \Gamma_A \cap W) \cong (W, \Gamma_B \cap W)$$ and $$(\hat{W}, \Gamma_A \cap \hat{W}) \cong (\hat{W}, \Gamma_B \cap \hat{W})$$.

Note that those ribbon graph cobordisms are restricted in the sense of Definition 3.2

\[\square\]

3.4. Sutured Heegaard Floer homology.

In this subsection, we introduce two equivalent definitions of sutured Heegaard Floer homology. The first one is due to Juhász [Juh06], based on balanced diagrams of balanced sutured manifolds. The other follows from the construction in Section 2.2, which is essentially due to Kronheimer and Mrowka [KM10]. These definitions are denoted by $SFH$ and $SHF$, respectively. The equivalence of these definitions was shown by Lekili [Lek13] and Baldwin and Sivek [BS20]. We will focus on the equality for graded Euler characteristics of two homologies.

Definition 3.37 ([Juh06 Section 2]). A balanced diagram $H = (\Sigma, \alpha, \beta)$ is a tuple satisfying the following.

1. $\Sigma$ is a compact, oriented surface with boundary.
2. $\alpha = \{\alpha_1, \ldots, \alpha_n\}$ and $\beta = \{\beta_1, \ldots, \beta_n\}$ are two sets of pairwise disjoint simple closed curves in the interior of $\Sigma$.
3. The maps $\pi_0(\partial \Sigma) \to \pi_0(\Sigma / \alpha)$ and $\pi_0(\partial \Sigma) \to \pi_0(\Sigma / \beta)$ are surjective.

For such triple, let $N$ be the 3-manifold obtained from $\Sigma \times [-1, 1]$ by attaching 3-dimensional 2-handles along $\alpha_i \times \{-1\}$ and $\beta_i \times \{1\}$ for $i = 1, \ldots, n$ and let $\nu = \partial \Sigma \times \{0\}$. A balanced diagram $(\Sigma, \alpha, \beta)$ is called compatible with a balanced sutured manifold $(M, \gamma)$ if the balanced sutured manifold $(N, \nu)$ is diffeomorphic to $(M, \gamma)$.

Suppose $H = (\Sigma, \alpha, \beta)$ is a balanced diagram with $g = g(\Sigma)$ and $n = |\alpha| = |\beta|$. Suppose $H$ satisfies the admissible condition in [Juh06 Section 3]. Consider two tori

$$T_\alpha := \alpha_1 \times \cdots \times \alpha_n$$

and

$$T_\beta := \beta_1 \times \cdots \times \beta_n$$

in the symmetric product

$$\text{Sym}^n \Sigma := \left( \prod_{i=1}^n \Sigma \right) / S_n.$$

The chain complex $SFC(H)$ is a free $\mathbb{F}_2$-module generated by intersection points $x \in T_\alpha \cap T_\beta$. Similar to the construction of $CF^-$, for a generic path of almost complex structures $J_x$ on $\text{Sym}^n \Sigma$, define the differential on $SFC(H)$ by

$$\partial_{J_x}(x) = \sum_{y \in T_\alpha \cap T_\beta} \sum_{\phi \in \pi_2(x, y)} \# M_{J}(\phi) \cdot y.$$

Theorem 3.38 ([Juh06 JTZ18]). Suppose $(M, \gamma)$ is a balanced sutured manifold. Then there is an admissible balanced diagram $H$ compatible with $(M, \gamma)$. The vector spaces $H(SFC(H), \partial_{J_x})$ for different choices of $H$ and $J_x$, together with some canonical maps, form a transitive system over $\mathbb{F}_2$. Let $SFH(M, \gamma)$ denote this transitive system and also the associated actual group. Moreover, there is a decomposition

$$SFH(M, \gamma) = \bigoplus_{\mathfrak{g} \in \text{Spin}^c(M, \partial M)} SFH(M, \gamma, \mathfrak{g}).$$
Remark 3.39. The group $SFH(M, \gamma)$ generalizes Heegaard Floer homology [OS04d] and knot Floer homology [OS04b, Ras03]. Suppose $Y$ is a closed 3-manifold and $K \subset Y$ is a knot. Let $Y(1)$ be obtained from $Y$ by removing a 3-ball and let $\delta$ be a simple closed curve on $\partial Y(1)$. Let $\gamma$ consist of two meridians of $K$. Then there are isomorphisms

$$SFH(Y(1), \delta) \cong \hat{HF}(Y)$$

and

$$SFH(Y(K), \gamma) \cong \hat{HF}_K(Y, K).$$

Definition 3.40. For a balanced sutured manifold $(M, \gamma)$, let the $\mathbb{Z}_2$-grading of $SFH(M, \gamma)$ be induced by the sign of intersection points of $T_\alpha$ and $T_\beta$ for some compatible diagram $H = (\Sigma, \alpha, \beta)$ (c.f. [FJR09, Section 3.4]). Suppose $H = H_1(M)/\text{Tors}$ and choose any $s_0 \in \text{Spin}^c(M, \gamma)$. The graded Euler characteristic of $SFH(M, \gamma)$ is

$$\chi_{gr}(SFH(M, \gamma)) := \sum_{s \in \text{Spin}^c(M, \gamma)} \chi_{gr}(SFH(M, \gamma, s)) \cdot p \circ \text{PD}(h) \in \mathbb{Z}[H]/\pm H,$$

where $\text{PD}: H^2(M, \partial M) \to H_1(M)$ is the Poincaré duality map and $p: H_1(M) \to H_1(M)/\text{Tors}$ is the projection map.

Theorem 3.41 ([FJR09]). Suppose $(M, \gamma)$ is a balanced sutured manifold. Then

$$\chi_{gr}(SFH(M, \gamma)) = p_*(\tau(M, \gamma)) \in \mathbb{Z}[H]/\pm H,$$

where $\tau(M, \gamma)$ is a (Turaev-type) torsion element computed from the map

$$\pi_1(R_-(\gamma)) \to \pi_1(M)$$

by Fox calculus and $p_*$ is induced by $p: H_1(M) \to H_1(M)/\text{Tors} = H$.

Then we define the second version of sutured Heegaard Floer homology.

Definition 3.42. Suppose $(M, \gamma)$ is a balanced sutured manifold and $(Y, R)$ is a closure of $(M, \gamma)$ as in Definition 2.3. Define

$$SHF(M, \gamma) := HF(Y|R) = \bigoplus_{s \in \text{Spin}^c(Y/R)} HF^+(Y, s).$$

Remark 3.43. By work of Kutluhan, Lee, and Taubes [KLT04], for any $s \in \text{Spin}^c(Y)$, there is an isomorphism

$$HF^+(Y, s) \cong \hat{HM}_*(Y, s) = \hat{HM}_*(Y, s).$$

The last group is used to define $SHF$ in [KM10].

Following the discussion in Section 2.2, we can prove the naturality of $SHF(M, \gamma)$ based on Floer’s excision theorem. Let $SHF(M, \gamma)$ be the transitive system corresponding to $SHF(M, \gamma)$.

Theorem 3.44 ([Lek13, Theorem 24], see also [BS14, Theorem 3.26]). Suppose $(M, \gamma)$ is a balanced sutured manifold and $(Y, R)$ is a closure of $(M, \gamma)$. Then there exists a balanced diagram $H = (\Sigma, \alpha, \beta)$ compatible with $(M, \gamma)$ and a singly-pointed Heegaard diagram $H' = (\Sigma', \alpha', \beta', z)$ of $Y$ so that the following holds.

(1) $\Sigma$ is a submanifold of $\Sigma'$.

(2) $\alpha$ and $\beta$ are subsets of $\alpha'$ and $\beta'$, respectively.

(3) Suppose $\alpha'' = \alpha \cup \alpha''$ and $\beta'' = \beta \cup \beta''$. There exists an intersection point $x_1 \in T_{\alpha''} \cap T_{\beta''}$ so that the map

$$f: SFC(H) \to CF^+(H'|R)$$

$$c \mapsto c \times x_1$$

is a quasi-isomorphism, where $CF^+(H'|R)$ is the chain complex of $HF^+(Y|R)$ associated to $H'$. 

Corollary 3.45 (Proposition 1.17). Suppose \((M, \gamma)\) is a balanced sutured manifold and \(H = H_1(M)/\text{Tors} \cong H^2(M, \partial M)/\text{Tors}\). We have

\[
\text{SFH}(M, \gamma) \cong \text{SHF}(M, \gamma)
\]

with respect to the grading associated to \(H\) and the \(\mathbb{Z}_2\) grading, up to a global grading shift.

In particular, we have

\[
\chi_{gr}(\text{SFH}(M, \gamma)) = \chi_{gr}(\text{SHF}(M, \gamma)) \in \mathbb{Z}[H]/\pm H,
\]

where \(\chi_{gr}(\text{SHF}(M, \gamma))\) is defined as in Definition 2.43.

Proof. It suffices to show the quasi-isomorphism in Theorem 3.44 respects spin\(^c\) structures and \(\mathbb{Z}_2\)-gradings.

Consider the \(\mathbb{Z}_2\)-gradings at first. Suppose \(c_1\) and \(c_2\) are two generators of \(SFC(\mathcal{H})\). Note that the \(\mathbb{Z}_2\)-grading of \(c_i\) is defined by the sign of the corresponding intersection point in \(T_\alpha \cap T_\beta\) for \(i = 1, 2\). For \(c_i \times x_1\), the \(\mathbb{Z}_2\)-grading is defined by mod 2 Maslov grading, which coincides with the sign of the corresponding intersection point in \(T_{\alpha'} \cap T_{\beta'}\). Thus, we have

\[
\text{gr}_2(c_1) - \text{gr}_2(c_2) = \text{gr}_2(c_1 \times x_1) - \text{gr}_2(c_2 \times x_1),
\]

where \(\text{gr}_2\) is the \(\mathbb{Z}_2\)-grading.

Then we consider spin\(^c\) structures. Consider \(c_i\) for \(i = 1, 2\) as above. From [Juh06] Lemma 4.7, there is a one chain \(\gamma_{c_1} - \gamma_{c_2}\) such that

\[
\mathcal{S}(c_1) - \mathcal{S}(c_2) = \text{PD}([\gamma_{c_1} - \gamma_{c_2}]),
\]

where \(\mathcal{S}(\cdot) : T_\alpha \cap T_\beta \to \text{Spin}^c(M, \partial M)\) is defined in [Juh06] Definition 4.5, and \(\text{PD} : H_1(M) \to H^2(M, \partial M)\) is the Poincaré duality map.

From [OS04d] Lemma 2.19, we have

\[
\mathcal{S}_z(c_1 \times x_1) - \mathcal{S}_z(c_2 \times x_1) = \text{PD}'(i_*(\gamma_{c_1} - \gamma_{c_2})),
\]

where \(\mathcal{S}_z(\cdot) : T_{\alpha'} \cap T_{\beta'} \to \text{Spin}^c(Y)\) is defined in [OS04d] Section 2.6 and \(\text{PD}' : H_1(Y) \to H^2(Y)\) is the Poincaré duality map, and \(i_* : H_1(M) \to H_1(Y)\) is the map induced by inclusion \(i : M \to Y\).

Hence we have

\[
c_1(\mathcal{S}_z(c_1 \times x_1)) - c_1(\mathcal{S}_z(c_2 \times x_1)) = 2\text{PD}'(i_*(\gamma_{c_1} - \gamma_{c_2})).
\]

Finally, the argument about graded Euler characteristics follows from definitions.

\[
\square
\]

4. The graded Euler characteristic of formal sutured homology

In this section, we prove the graded Euler characteristic of formal sutured homology is independent of the choice of the Floer-type theory. Throughout this section, we assume that \(H\) is a Floer-type theory, i.e., it satisfies all three Axioms (A1), (A2), and (A3). For simplicity, we say ‘a property is independent of \(H\)’ if a property is independent of the choice of the Floer-type theory. Suppose \((M, \gamma)\) is a balanced sutured manifold. If the admissible surfaces and the closure of \((M, \gamma)\) are fixed, then the graded Euler characteristic \(\chi_{gr}(\text{SH}(M, \gamma))\) in Definition 2.42 is considered as a well-defined element in \(\mathbb{Z}[H_1(M)/\text{Tors}]\), rather than \(\mathbb{Z}[H_1(M)/\text{Tors}]/(H_1(M)/\text{Tors})\); see Remark 2.43. Note that in this subsection, we avoid using \(H\) to denote \(H_1(M)/\text{Tors}\) and the symbol \(H\) usually denotes a handlebody.
4.1. Balanced sutured handlebodies.

In this subsection, we deal with $\mathbb{Z}^n$-gradings for a balanced sutured handlebody. We start with the following lemma about the sign ambiguity.

**Lemma 4.1.** Suppose $(M, \gamma)$ is a balanced sutured manifold, $S \subset (M, \gamma)$ is an admissible surface. Suppose $(Y_1, R_1)$ and $(Y_2, R_2)$ are two closures of $(M, \gamma)$ of the same genus so that $S$ extends to closed surfaces $\bar{S}_1$ and $\bar{S}_2$ as in Subsection 2.3. If $\chi_{\mathbb{Z}^n}(H(Y_1|R_1))$ is already determined without the sign ambiguity, then $\chi_{\mathbb{Z}^n}(H(Y_2|R_2))$ is determined without the sign ambiguity from $\chi_{\mathbb{Z}^n}(H(Y_1|R_1))$ and the topological data of $(Y_1, R_1)$ and $(Y_2, R_2)$.

**Proof.** In Subsection 2.2, we construct a canonical map

$$\Phi_{12} : H(Y_1|R_1) \to H(Y_2|R_2).$$

From the proof of Theorem 2.24, the canonical map $\Phi_{12}$ necessarily preserves the grading induced by $S$. From the construction of $\Phi_{12}$ in Subsection 2.2, the canonical map is a composition of a few cobordism maps (or the inverse). Then the $Z_2$-grading shift follows from Axiom (A3-3).

Next, we consider gradings associated to admissible surfaces. To fix the ambiguity of $H_1(M)/\text{Tors}$, we will choose the choices of admissible surfaces. For sutured handlebodies, we start with embedded disks.

**Proposition 4.2.** Suppose $H$ is a genus $g > 0$ handlebody and $\gamma \subset \partial H$ is a closed oriented 1-submanifold so that $(H, \gamma)$ is a balanced sutured manifold. Pick $D_1, \ldots, D_g$ a set of pairwise disjoint meridian disks in $H$ so that $[D_1], \ldots, [D_g]$ generate $H_2(H, \partial H)$. Then for any fixed multi-grading $i = (i_1, \ldots, i_g) \in \mathbb{Z}^g$ associated to $D_1, \ldots, D_g$, the Euler characteristic

$$\chi(\text{SH}(-H, -\gamma, i)) \in \mathbb{Z}/\{\pm 1\}$$

depends only on $(H, \gamma)$, $D_1, \ldots, D_g$ and $i \in \mathbb{Z}^g$, and is independent of $H$. Furthermore, if a particular closure of $(-H, -\gamma)$ is fixed, then the sign ambiguity can be removed.

**Proof.** We fix the handlebody $H$ and the set of disks $D_1, \ldots, D_g \subset H$. For any suture $\gamma$ on $\partial H$, define

$$I(\gamma) = \min_{\gamma' \text{ is isotopic to } \gamma} \sum_{j=1}^g |D_j \cap \gamma'|,$$

where $| \cdot |$ denotes the number of points. We prove the proposition by induction on $I(\gamma)$. Since $|\gamma| = 0 \in H_1(\partial H)$, we know $|D_j \cap \gamma|$ is always even for $j = 1, \ldots, g$.

Note that an isotopy of $\gamma$ can be understood as combinations of positive and negative stabilizations in the sense of Definition 2.36 and the grading shifting behavior under such isotopies (stabilizations) is described by Proposition 2.39 which is determined purely by topological data and is independent of $H$. Hence we can assume that the suture $\gamma$ has already realized $I(\gamma)$.

First, if $I(\gamma) < 2g$, then there exists a meridian disk $D_j$ with $D_j \cap \gamma = \emptyset$. Then it follows from Theorem 2.32 that $\text{SH}(-H, -\gamma) = 0$ since $-H$ is irreducible while $(-H, -\gamma)$ is not taut. Hence for any multi-grading $i \in \mathbb{Z}^g$, we have $\chi(\text{SH}(-H, -\gamma, i)) = 0$.

If $I(\gamma) = 2g$, then either there exists some integer $j$ so that $D_j \cap \gamma = \emptyset$ or for $j = 1, \ldots, g$, we have $|D_j \cap \gamma| = 2$. In the former case, we know that $\text{SH}(-H, -\gamma) = 0$ and hence $\chi(\text{SH}(-H, -\gamma, i)) = 0$ for any multi-grading $i \in \mathbb{Z}^g$. In the later case, we know that $(-H, -\gamma)$ is a product sutured manifold. It follows from Proposition 2.34 and Proposition 2.30 that

$$\text{SH}(-H, -\gamma) = \text{SH}(-H, -\gamma, 0) \cong \mathbb{F}.$$
Hence
\[
\chi(\text{SH}(-H, -\gamma, i)) = \begin{cases} 
\pm 1 & i = 0 = (0, \ldots, 0) \\
0 & i \in \mathbb{Z}^g \setminus \{0\}
\end{cases}
\]

Note that the ambiguity \(\pm 1\) comes from the choice of the closure. If we choose a particular closure \(Y\) of \((-H, -\gamma)\), then the Euler characteristic has no sign ambiguity. Since \((H, \gamma)\) is a product sutured manifold, there is a ‘standard’ closure \((S^1 \times \Sigma, \{1\} \times \Sigma)\) as in [KM10b]. By Axiom (A3-2), we have
\[
\chi(H(S^1 \times \Sigma, \{1\} \times \Sigma)) = -1.
\]

Then for any other closure \((Y, R)\), by Lemma 4.1 \(\chi_{gr}(\text{SH}(Y|R))\) has no sign ambiguity.

Now suppose we have proved that, for all \(\gamma\) so that \(I(\gamma) < 2n\), the Euler characteristic of \(\text{SH}(-H, -\gamma, i)\), viewed as an element in \(\mathbb{Z}/(\pm 1)\), is independent of \(H\), and that when we choose any fixed closure of \((-H, -\gamma)\), the sign ambiguity can be removed. Next we deal with the case when \(I(\gamma) = 2n\).

Note that we have dealt with the base case \(I(\gamma) \leq 2g\), so we can assume that \(n \geq g + 1\). Hence, without loss of generality, we can assume that \(|D_1 \cap \gamma| \geq 4\). Within a neighborhood of \(\partial D_1\), the suture \(\gamma\) can be depicted as in Figure 13. We can pick the bypass arc \(\alpha\) as shown in the same figure. From Proposition 2.44 for any multi-grading \(i \in \mathbb{Z}^g\), we have an exact triangle

\[
\text{(4.1)}
\]

\[
\text{SH}(-H, -\gamma', i) \leftarrow \text{SH}(-H, -\gamma'', i) \rightarrow \text{SH}(-H, -\gamma, i)
\]

\[\alpha\]
\[\partial D_1\]
\[\gamma\]
\[\gamma'\]
\[\gamma''\]

**Figure 13.** The bypass arc \(\alpha\) that reduces the intersection function \(I\).

Note that the suture \(\gamma'\) and \(\gamma''\) are determined by the original suture \(\gamma\) and the bypass arc \(\alpha\), which are all topological data. From Figure 13 it is clear that
\[
I(\gamma') \leq I(\gamma) - 2 \quad \text{and} \quad I(\gamma'') \leq I(\gamma) - 2.
\]

Hence the inductive hypothesis applies, and we know that the Euler characteristics of \(\text{SH}(-H, -\gamma'', i)\) and \(\text{SH}(-H, -\gamma', i)\) can be fixed independently of \(H\). Note that the maps in the bypass exact triangle (4.1) are described by Proposition 2.20. Hence we conclude that the Euler characteristic of \(\text{SH}(-H, -\gamma, i)\) is also independent of \(H\). Thus, we finish the proof by induction. \(\Box\)

Next, we deal with gradings associated to general admissible surfaces.
Proposition 4.3. Suppose $H$ is a genus $g$ handlebody, and $S$ is a properly embedded surface in $H$. Suppose $\gamma \subset \partial H$ is a suture so that $(H, \gamma)$ is a balanced sutured manifold and $S$ is an admissible surface. Then the Euler characteristic

$$\chi(SH(-H, -\gamma, S, j)) \in \mathbb{Z}/\{\pm 1\}$$

depends only on $(H, \gamma)$, $S$, and $j \in \mathbb{Z}$ and is independent of $H$. Furthermore, if we fix a particular closure of $(-H, -\gamma)$, then the sign ambiguity can also be removed.

Before proving the proposition, we need the following lemma.

Lemma 4.4. Suppose $(M, \gamma)$ is a balanced sutured manifold and $S \subset (M, \gamma)$ is a properly embedded admissible surface. Suppose $\alpha$ is a boundary component of $S$ so that $\alpha$ bounds a disk $D \subset \partial M$ and $|\alpha \cap \gamma| = 2$. Let $S'$ be the surface obtained by taking the union $S \cup D$ and then push $D$ into the interior of $M$. Then for any $i \in \mathbb{Z}$, we have

$$SH(M, \gamma, S, i) = SH(M, \gamma, S', i).$$

Proof. Push the interior of $D$ into the interior of $M$ and make $D \cap S' = \emptyset$. It is clear that

$$[S] = [S' \cup D] \in H_2(M, \partial M)$$

and $\partial S = \partial(S' \cup D)$. In Subsection 2.3 when constructing the grading associated to $S' \cup D$, we can pick a closure $(Y, R)$ of $(M, \gamma)$, so that $S'$ and $D$ extend to closed surfaces $S'$ and $\bar{D}$ in $Y$, respectively. Since $|\partial D \cap \gamma| = 2$, we know that $\bar{D}$ is a torus. Since $\partial S = \partial(S' \cup D)$, we know that $S$ also extends to a closed surface $\bar{S}$ and from the fact that $[\bar{S}] = [S' \cup D]$ we know that

$$[\bar{S}] = [S' \cup \bar{D}] = [S'] + [\bar{D}].$$

Since $\bar{D}$ is a torus, from Axioms (A1-4) and (A1-6), we know that the decompositions of $H(Y|R)$ with respect to $\bar{S}$ and $S'$ are the same. Thus it follows that

$$SH(M, \gamma, S, i) = SH(M, \gamma, S', i).$$

Proof of Proposition 4.3. It is a basic fact that the map

$$\bar{\partial}_g : H_2(H, \partial H) \to H_3(\partial H)$$

is injective, and $H_2(H, \partial H)$ is generated by $g$ meridian disks, which we fix as $D_1, \ldots, D_g$. Hence we assume that

$$[S] = a_1[D_1] + \cdots + a_g[D_g] \in H_2(H, \partial H).$$

Case 1. $\partial S$ consists of only $\partial D_i$, i.e.,

$$\partial S = \bigcup_{i=1}^g (\omega_{a_i} \partial D_i),$$

where $\omega_{a_i} \partial D_i$ means the union of $a_i$ parallel copies of $\partial D_i$.

Then it follows immediately from the construction of the grading and Axiom (A1-6) that

$$SH(-H, -\gamma, S, j) = SH(-H, -\gamma, \bigcup_{i=1}^g (\omega_{a_i} D_i), j)$$

$$= \bigoplus_{j_1 + \cdots + j_g = j} SH(-H, -\gamma, (D_1, \ldots, D_g), (j_1, \ldots, j_g)).$$

Hence this case follows from Proposition 4.2.
Case 2. \( \partial S \) contains some component that is not parallel to \( \partial D_i \) for \( j = 1, \ldots, g \).

**Step 1.** We modify \( S \) and show that it suffices to deal with the case when \( S \cap D_j = \emptyset \) for \( j = 1, \ldots, g \).

Note that \( \text{im}(\partial_a) \subset H_1(\partial H) \) is generated by \([\partial D_1], \ldots, [\partial D_g]\), so we have \( \partial S \cdot \partial D_i = 0 \) for \( j = 1, \ldots, g \). Here \( \cdot \) denotes the algebraic intersection number of two oriented curves on \( \partial H \). This means that for \( j = 1, \ldots, g \), the intersection points of \( \partial D_i \) with \( \partial S \) can be divided into pairs. Suppose two intersection points of \( \partial D_1 \) with \( \partial S \) of opposite signs are adjacent to each other on \( \partial D_1 \), as depicted in Figure 14. We can perform a cut and paste surgery along \( \partial D_1 \) and \( S \) to obtain a new surface \( S_1 \). From the same figure, it is clear that after isotopy, we can make

\[
|\partial D_1 \cap \partial S_1| \leq |\partial D_1 \cap \partial S| - 2.
\]

![Figure 14](image1)

**Figure 14.** The cut and paste surgery on \( D_1 \) and \( S \).

Note that if we perform a cut and paste surgery along \( S_1 \) and \( -D_1 \), we obtain another surface \( S_2 \). From Figure 15 it is clear that \( \partial S_2 = \partial S \cup \theta \), where \( \theta \) is the union of some null-homotopic closed curves on \( \partial H \). We can isotope \( S_2 \) to make each component of \( \theta \) intersects the suture twice. Let \( S_3 \) be the resulting surface of such an isotopy and \( S_4 \) be the surface obtained from \( S_3 \) by capping off every component of \( \theta \). Then we have

\[
[S] = [S_4] \in H_2(H, \partial H) \text{ and } \partial S = \partial S_4.
\]
Hence from Lemma 4.3 we know that
\[\text{SH}(-H, -\gamma, S, j) = \text{SH}(-H, \gamma, S_1, j)\]
\[= \text{SH}(-H, \gamma, S_3, j)\]
\[= \text{SH}(-H, -\gamma, s_2, j + j(S_2, S_3))\]
\[= \bigoplus_{j_1 + j_2 = j} \text{SH}(-H, -\gamma, \langle D_1, S_1 \rangle, (j_1, j_2))\]

By Proposition 2.39, the shift \(j(S_2, S_3)\) depends on the isotopy from \(S_2\) to \(S_3\), which is determined by the topological data and is independent of \(H\). Hence we reduce the problem to understanding the Euler characteristic of \(\text{SH}(-H, -\gamma)\) with multi-grading associated to \(\langle D_1, S_1 \rangle\), with
\[|\partial D_1 \cap \partial S_1| \leq |\partial D_1 \cap \partial S| - 2.\]

Repeating this argument, we finally reduce to the problem of understanding the Euler characteristic of \(\text{SH}(-H, -\gamma)\) with multi-grading associated to \(\langle D_1, \ldots, D_g, S_g \rangle\), with
\[\partial D_i \cap \partial S_g = \emptyset \text{ for } j = 1, \ldots, g.\]

**Step 2.** We modify \(S\) further to reduce to Case 1.
If every component of \(\partial S_g\) is homotopically trivial, then we know that
\[\{S_g\} = 0 \in \text{H}_2(H, \partial H),\]

since the map \(H_2(H, \partial H) \rightarrow H_1(\partial H)\) is injective. We isotope each component of \(\partial S_g\) by stabilization to make it intersect the suture \(\gamma\) twice and then cap it off by a disk. The resulting surface \(S_{g+1}\) is a homotopically trivial closed surface in \(H\), so \(\text{SH}(-H, -\gamma)\) is totally supported at grading 0 with respect to \(S_{g+1}\). The grading shift between \(S_g\) and \(S_{g+1}\) can then be understood by Proposition 2.39 and is independent of \(H\).

Note that \(\partial H \setminus (\partial D_1 \cup \cdots \cup \partial D_g)\) is a \(2g\)-punctured sphere, so \(\partial S\) is homotopically trivial when removing punctures on the sphere. If some component \(C\) of \(\partial S_g\) is not null-homotopic, then \(C\) is obtained from some \(\partial D_j\) by performing handle slides (or equivalently band sums) over \(\partial D_1, \ldots, \partial D_g\) for some times.

If we isotope \(C\) to make it intersect some \(\partial D_i\) twice and then apply the cut and paste surgery, the resulting curve is isotopic to the one obtained by performing a handle slide over \(\partial D_i\). Explicitly, in Figure 1 suppose two right endpoints of arcs in \(\partial S\) (the green arcs) are connected, then the right part of \(\partial S_1\) is a trivial circle, and the left part of \(\partial S_1\) is obtained from \(\partial S\) by performing a handle slide over \(\partial D_1\). Thus, we can apply the cut and paste surgery for many times, which is equivalent to performing handle slides over \(\partial D_1, \ldots, \partial D_g\) for some times. Finally, we reduce \(C\) to the curve isotopic to \(\partial D_j\). Then we reduce the problem to understanding the Euler characteristic of \(\text{SH}(-H, -\gamma)\) with multi-grading associated to \(\langle D_1, \ldots, D_g, S_{g+2} \rangle\), where \(S_{g+2}\) is a surface so that each component of \(\partial S_{g+2}\) is parallel to \(\pm \partial D_i\) for some \(i\). Case 1 applies to \(S_{g+2}\), and we finish the proof. \(\square\)

**Corollary 4.5.** Suppose \(H\) is a handlebody and \(\gamma\) is a suture on \(\partial H\) so that \((H, \gamma)\) is a balanced sutured manifold. Suppose \(S_1, \ldots, S_n\) are properly embedded admissible surfaces in \((H, \gamma)\). Then the Euler characteristic
\[\chi(\text{SH}(-H, -\gamma, (S_1, \ldots, S_n), (i_1, \ldots, i_n))) \in \mathbb{Z}/\{\pm 1\}\]
depends only on \((H, \gamma), S_1, \ldots, S_n, (i_1, \ldots, i_n)\) \(\in \mathbb{Z}^n\), and is independent of \(H\). Furthermore, if we fix a particular closure of \((-H, -\gamma)\), then the sign ambiguity can also be removed.
Thus, we define (2) If we attach a contact 2-handle along $1$-handle can be described explicitly as follows. In $(N_0, \gamma_{N,0})$, there is an annulus $A$ bounded by $\mu$ and its push-off $\mu'$.

Step 2. We show $\iota : \text{SH}(-M, -\gamma_M, S, i) \to \text{SH}(-N_0, -\gamma_{N,0}, S_N, i)$. As discussed above, $(N_0, \gamma_{N,0})$ is obtained from $(M, \gamma_M)$ by a product 1-handle attachment. This product 1-handle can be described explicitly as follows. In $(N_0, \gamma_{N,0})$, there is an annulus $A$ bounded by $\mu$. We can cap off $\mu'$ by the disk coming from the 0-surgery, and hence obtain a disk $D$ with $\partial D = \mu$. By assumption, we know that $|\partial D \cap \gamma_{N,0}| = |\mu \cap \gamma_N| = 2$. Hence $D$ is a compressing disk that intersects the suture twice.

We perform a sutured manifold decomposition on

**Proof.** The proof is similar to that for Proposition 4.3.

### 4.2. Gradings about contact 2-handle attachments.

In this subsection, we prove a technical proposition about the grading behavior for the map associated to contact 2-handle attachments.

Suppose $M$ is a compact oriented 3-manifold with boundary, and $S \subset M$ is a properly embedded surface. Suppose $\alpha \subset M$ is a properly embedded arc that intersects $S$ transversely and $\partial \alpha \cap \partial S = \emptyset$. Let $N = M \setminus \text{int}(N(\alpha))$, $S_N = S \cap N$, and $\mu \subset \partial N$ be a meridian of $\alpha$ that is disjoint from $S_N$. Let $\gamma_N$ be a suture on $\partial N$ that intersects $\alpha$ twice. We construct a map $\text{SH}(-N, -\gamma_N) \to \text{SH}(-M, -\gamma_M)$ as follows.

From [BS16a, Section 4.2], there is a map $C_{\mu} : \text{SH}(-N, -\gamma_N) \to \text{SH}(-M, -\gamma_M)$ constructed as follows.

Push $\mu$ into the interior of $N$ to become $\mu'$. Suppose $(N_0, \gamma_{N,0})$ is the manifold obtained from $(N, \gamma_N)$ by a 0-surgery along $\mu'$ with respect to the framing from $\partial N$. Equivalently, $(N_0, \gamma_{N,0})$ can be obtained from $(M, \gamma_M)$ by attaching a 1-handle. Since $\mu' \subset \text{int}(N)$, the construction of the closure of $(N, \gamma_N)$ does not affect $\mu'$. Thus, we can construct a cobordism between closures of $(N, \gamma_N)$ and $(N_0, \gamma_{N,0})$ by attaching a 4-dimensional 2-handle associated to the surgery on $\mu'$. This cobordism induces a cobordism map $C_{\mu'} : \text{SH}(-N, -\gamma_N) \to \text{SH}(-N_0, -\gamma_{N,0})$.

It is shown in [BS16a, Section 4.2] (or also [KM10b, Section 6]) that attaching a product 1-handle does not change the closure, so there is an identification $\iota : \text{SH}(-M, -\gamma_M) \cong \text{SH}(-N_0, -\gamma_{N,0})$.

Thus, we define $C_{\mu} = \iota^{-1} \circ C_{\mu'}$.

The main result of this subsection is the following proposition.

**Proposition 4.6.** Consider the setting as above. For any $i \in \mathbb{Z}$, we have $C_{\mu}(\text{SH}(-N, -\gamma_N, S_N, i)) \subset \text{SH}(-M, -\gamma_M, S, i)$.

**Proof.** Step 1. We consider the grading behavior of the map $C_{\mu'}$ for gradings associated to $S_N$ and $S$.

Since $\mu$ is disjoint from $S$, we can also make $\mu'$ disjoint from $S_N = S \cap N$. As a result, the surface $S_N$ survives in $(N_0, \gamma_{N,0})$. From Axiom (A1-7), the cobordism map associated to the 0-surgery along $\mu'$ preserves the grading associated to $S_N$: $C_{\mu'}(\text{SH}(-N, -\gamma_N, S_N, i)) \subset \text{SH}(-N_0, -\gamma_{N,0}, S_N, i)$.

Step 2. We show $\iota : \text{SH}(-M, -\gamma_M, S, i) \to \text{SH}(-N_0, -\gamma_{N,0}, S, i)$.

As discussed above, $(N_0, \gamma_{N,0})$ is obtained from $(M, \gamma_M)$ by a product 1-handle attachment. This product 1-handle can be described explicitly as follows. In $(N_0, \gamma_{N,0})$, there is an annulus $A$ bounded by $\mu$ and its push-off $\mu'$. We can cap off $\mu'$ by the disk coming from the 0-surgery, and hence obtain a disk $D$ with $\partial D = \mu$. By assumption, we know that $|\partial D \cap \gamma_{N,0}| = |\mu \cap \gamma_N| = 2$. Hence $D$ is a compressing disk that intersects the suture twice.
Then the graded Euler characteristic \( p \) depends only on \( n \).

**Remark** Suppose that \( \alpha \) consists of a few copies of meridians of \( \gamma \) and is obtained from \( \gamma \) by removing disks containing intersection points in \( \alpha \). We can pick \( \alpha \) such that \( \partial \alpha \cap \partial S = \emptyset \). Hence we conclude that \( \partial \alpha \cap \partial S = \emptyset \).

**Step 3.** We show \( \chi \) that the map \( \alpha \) preserves the gradings as claimed.

From (A1-6), we know that the map \( \alpha \) preserves the gradings as claimed.

Indeed, we can pick \( \alpha \) such that \( \partial \alpha \cap \partial S = \emptyset \). Hence we conclude that \( \partial \alpha \cap \partial S = \emptyset \).

After performing the 0-surgery along \( \mu' \), we know that the surface \( S_N \subset \gamma_{\alpha} \) is compressible. Indeed, we can pick \( \mu'' \subset \text{int}(S_N) \) parallel to \( \mu \). From this description, we can consider the product 1-handle attached to \( S_N \) by \( \partial \alpha \). Performing a compression along the disk \( D' \), we know that \( S_N \) becomes the disjoint union of a disk \( D'' \) and the surface \( S \subset \gamma_{\alpha} \). Note \( \partial D'' \) is parallel to the disk \( D \) discussed above. Since \( \partial \) preserves the gradings as claimed.

From (A1-6), we know that
\[
\chi(-N_0, -\gamma_{\alpha}, S, i) = \chi(-N_0, -\gamma_{\alpha}, S, D'', i)
\]
\[
= \sum_{i_1 + i_2 = i} \chi(-N_0, -\gamma_{\alpha}, (S, D''), (i_1, i_2)).
\]

Since the disk \( D'' \) intersects \( \gamma_{\alpha} \) twice, from term (2) of Proposition 2.30 we know that
\[
\chi(-N_0, -\gamma_{\alpha}, S, D'', 0) = \chi(-N_0, -\gamma_{\alpha}, 0).
\]

Hence we conclude that
\[
\chi(-N_0, -\gamma_{\alpha}, S, i) = \sum_{i_1 + i_2 = i} \chi(-N_0, -\gamma_{\alpha}, (S, D''), (i_1, i_2))
\]
\[
= \chi(-N_0, -\gamma_{\alpha}, S, i).
\]

**Remark 4.7.** Theorem 4.6 is a generalization of [BLY20, Lemma 2.2], where \( \alpha \) is a tangle and \( S_N \) is an annulus.

**4.3. General balanced sutured manifolds.**

In this subsection, we prove the main theorem of this section, which is a restatement of the second part of Theorem 1.13.

**Theorem 4.8.** Suppose \((M, \gamma)\) is a balanced sutured manifold and \(\{S_1, \ldots, S_n\}\) is a collection of properly embedded admissible surfaces. Then the Euler characteristic
\[
\chi(\langle M, \gamma, (S_1, \ldots, S_n), (i_1, \ldots, i_n)\rangle)
\]
depends only on \((M, \gamma)\), \(S_1, \ldots, S_n\), and \((i_1, \ldots, i_n) \in \mathbb{Z}^n\), and is independent of \(H\).

**Corollary 4.9.** Suppose \((M, \gamma)\) is a balanced sutured manifold and suppose \(H = H_1(M)/\text{Tors} \). Then the graded Euler characteristic
\[
\chi_{gr}(\langle M, \gamma \rangle) = \chi_{gr}(\langle M, \gamma \rangle) \in \mathbb{Z}[H]/\pm H
\]
is independent of the choice of the fixed genus \( g \) of closures.

**Proof.** From Corollary 3.45 and Theorem 4.8 we know
\[
\chi_{\text{gr}}(\text{SH}(M, \gamma)) = \chi_{\text{gr}}(\text{SFH}(M, \gamma)) \in \mathbb{Z}[H]/\pm H,
\]
where the right hand side is independent of the choice of the fixed genus \( g \) of closures. \( \square \)

**Proof of Theorem 4.8.** First we can attach product 1-handles disjoint from \( S_1, \ldots, S_n \). From [BS16a Section 4.2], attaching a product 1-handle does not change the closure and hence does not make any difference to the multi-grading associated to \((S_1, \ldots, S_n)\). Hence we can assume that \( \gamma \) is connected from now on. From [LY20 Section 3.1], we can pick a disjoint union of properly embedded arcs
\[
\alpha = \alpha_1 \cup \cdots \cup \alpha_m
\]
so that
(1) for \( k = 1, \ldots, m \), we have \( \partial \alpha_k \cap R_+(\gamma) \neq \emptyset \) and \( \partial \alpha_k \cap R_-(\gamma) \neq \emptyset \),
(2) \( M \setminus \text{int}(N(\alpha)) \) is a handlebody.

Then we apply the arguments involved in [LY20 Section 3.2]: since \( \gamma \) is connected, we can pick pairwise disjoint arcs \( \zeta_1, \ldots, \zeta_m \) so that for any \( k = 1, \ldots, m \), we have
\[
\partial \zeta_k = \partial \alpha_k \text{ and } |\zeta_k \cap \gamma| = 1.
\]

For any \( k = 1, \ldots, g \), let \( \beta_k \subset \zeta_k \) be a neighborhood of the intersection point \( \zeta_k \cap \gamma \) and let
\[
\zeta_k \setminus \beta_k = \zeta_{k,+} \cup \zeta_{k,-},
\]
where \( \zeta_{k,\pm} \subset R_{\pm}(\gamma) \). Push the interior of \( \beta_k \) into the interior of \( M \) to make it a properly embedded arc, which we still call \( \beta_k \). Let
\[
\beta = \beta_1 \cup \cdots \cup \beta_m.
\]

Let \( N = M \setminus \text{int}(N(\beta)) \), and let \( \gamma_N \) be the disjoint union of \( \gamma \) and a meridian for each component of \( \beta \). It is explained in [LY20 Section 3.2] that \((N, \gamma_N)\) can be obtained from \((M, \gamma)\) by attaching product 1-handles disjoint from \( S_1, \ldots, S_m \), so there is a canonical identification
\[
\text{SH}(-M, -\gamma, (S_1, \ldots, S_n), (i_1, \ldots, i_n)) = \text{SH}(-N, -\gamma_N, (S_1, \ldots, S_n), (i_1, \ldots, i_n))
\]

Let \( H = M \setminus \text{int}(N(\alpha \cup \beta)) \). It is straightforward to check that \( H \) is a handlebody. Let \( \Gamma_\mu \) be the disjoint union of \( \gamma \) and a meridian for each component of \( \alpha \cup \beta \). Let the suture \( \Gamma_0 \) be obtained from \( \Gamma_\mu \) by performing band sums along \( \zeta_{k,+} \) and \( \zeta_{k,-} \) for \( k = 1, \ldots, m \). See Figure 16. It is straightforward to check that \((N, \gamma_N)\) can be obtained from \((H, \Gamma_0)\) by attaching contact 2-handles along the meridians of all components of \( \alpha \).

We prove the theorem in the case when \( m = 1 \), while the general case follows from a straightforward induction. If \( m = 1 \), then \( \alpha \) is connected. Suppose \( \mu \) is the meridian of \( \alpha \). As explained in Subsection 4.2, attaching a contact 2-handle along \( \mu \) is the same as performing a 0-surgery along a push-off \( \mu' \) of \( \mu \). There is an exact triangle associated to the surgeries along \( \mu' \) that is discussed in [LY20 Section 3.2] (see also [GLW19 Section 3.1]):

\[
(4.2) \quad \text{SH}(-N, -\gamma_N) \quad \text{SH}(-H, -\Gamma_0) \quad \text{SH}(-H, -\Gamma_1)
\]

The map \( C_\mu \) is the map associated to the contact 2-handle attachment as discussed in Subsection 4.2. The suture \( \Gamma_1 \) is obtained from \( \Gamma_0 \) by twisting along \( (-\mu) \) once. For \( j = 1, \ldots, n \), let \( S_{j,H} = S_j \cap H \).
Since µ is disjoint from \( S_{j,H} \) for \( j = 1, \ldots, n \), the proof of Proposition 4.6 implies there is a graded version of the exact triangle (4.2):

\[
\text{SH}(\mu, (i_1, \ldots, i_n)) \rightarrow \text{SH}(\nu, (S_1, \ldots, S_n), (i_1, \ldots, i_n)) \rightarrow \text{SH}(\Gamma_0, (S_1, \ldots, S_n), ((i_1, \ldots, i_n))).
\]

Then Theorem 4.8 follows from Proposition 2.4 and Corollary 4.5.

5. The canonical mod 2 grading

Throughout this section, we focus on special cases of balanced sutured manifolds obtained from connected closed 3-manifolds and knots in them (c.f. Remark 3.39).

**Definition 5.1.** Suppose that \( Y \) is a closed 3-manifold and \( z \in Y \) is a basepoint. Let \( Y(1) \) be obtained from \( Y \) by removing a 3-ball containing \( z \) and let \( \delta \) be a simple closed curve on \( \partial Y(1) \cong S^2 \). Suppose that \( K \subset Y \) is a knot and \( w \) is a basepoint on \( K \). Let \( Y(K) \) be the knot complement of \( K \) and let \( \gamma = m \cup (-m) \) consist of two meridians with opposite orientations of \( K \) near \( w \). Then \( (Y(1), \delta) \) and \( (Y(K), \gamma) \) are balanced sutured manifolds. Define

\[
\mathcal{H}(Y, z) := \text{SH}(Y(1), \delta) \quad \text{and} \quad \mathcal{KH}(Y, K, w) := \text{SH}(Y(K), \gamma).
\]

**Convention.** Different choices of the basepoints give isomorphism vector spaces. Since we only care about the isomorphism class of the vector spaces, we omit the basepoints and simply write \( \mathcal{H}(Y) \) and \( \mathcal{KH}(Y, K) \) instead.

To be more specific and consistent with \[ LY20 \], in this section, we focus on instanton theory. Based on the discussion in Subsection 2.1, we specify the Floer homology \( \mathcal{H}(Y) \) and the cobordism
map $H(W)$ to $I^w(Y)$ and $I(W,\nu)$. For a connected closed 3-manifold, the framed instanton Floer homology $I^f(Y)$ defined in [KMM11a] is isomorphic to $\tilde{H}(Y)$ when $H$ is instanton theory. Hence we replace $\tilde{H}(Y)$ by $I^f(Y)$ throughout this section. Also we replace $SH$ and $KH$ by $SHI$ and $KHI$, respectively. Recall that the definitions of $SHI$ and $KHI$ a priori depend on the choice of a fixed and large genus $g$ of closures. We write $SHI^g$ and $KHI^g$ explicitly in this section. However, for instanton theory, closures of different genus induce isomorphic groups and we can use closures of genus one to define sutured instanton homology (c.f. [KM10b] Section 7).

In this section, we discuss the canonical $\mathbb{Z}_2$-grading on $KHI^g$ and the decomposition of $I^g$ in Theorem 1.20. For other Floer-type theories, the construction in [LY20] Section 4.3 can be adapted without essential changes, and we have a decomposition for $\tilde{H}(Y)$ similar to that in Theorem 1.20. The results in this section also apply without essential changes except for arguments about different genera of closures (e.g. Proposition 5.10), which use Floer’s excision theorem along a surface of genus one.

### 5.1. The case of an unknot

In this subsection, we study the model case: the unknot $U$ in $S^3$. Suppose $\mu_U$ and $\lambda_U$ are the meridian and the longitude of $U$, respectively. The knot complement is identified with a solid torus $S^1 \times D^2$: \begin{equation}
\rho: S^3(U) \xrightarrow{\cong} S^1 \times D^2,
\end{equation}
where $\rho(\mu_U) = S^1 \times \{1\}$, and $\rho(\lambda_U) = \{1\} \times \partial D^2$. For co-prime integers $x$ and $y$, let $\gamma(x,y) = \gamma_x \lambda_U + y \mu_U \subset \partial S^3(U)$ be the suture consisting of two disjoint simple closed curves representing $\pm(x \lambda_U + y \mu_U)$.

**Convention.** Note $\gamma(x,y) = \gamma(-x,-y)$. From term (4) in Proposition 2.30, the orientation of the suture does not influence the isomorphism type of formal sutured homology. Hence we do not care about the orientation of the suture, and we always assume $y \geq 0$.

We describe a closure of the balanced sutured manifold $(S^3(U), \gamma(x,y))$ as follows. Let $\Sigma$ be a connected closed surface of genus $g \geq 1$. Suppose $Y_\Sigma = S^1 \times \Sigma$ and $\Sigma = \{1\} \times \Sigma$. Pick a non-separating simple closed curve $\alpha \subset \Sigma$ and suppose its complement is $Y_\Sigma(\alpha) = Y_\Sigma \setminus \text{int}(N(\alpha))$. There is a framing on $\partial Y_\Sigma(\alpha)$ induced by the surface $\Sigma$. Let $\mu_\alpha$ and $\lambda_\alpha$ be the corresponding meridian and longitude, respectively. Also, suppose $p \in \Sigma$ is a point disjoint from $\alpha$. According to the discussion in Section 2, we can form a closure $(\tilde{Y}, R, \omega)$ of $(S^3(U), \gamma(x,y))$ as follows: \begin{equation}
\tilde{Y} = S^3(U) \cup Y_\Sigma(\alpha), R = \Sigma, \text{ and } \omega = S^1 \times \{pt\},
\end{equation}
where $\phi: \partial S^3(U) \xrightarrow{\cong} \partial Y(\alpha)$ is an orientation reversing diffeomorphism such that
\begin{equation}
\phi(x \lambda_U + y \mu_U) = \lambda_\alpha.
\end{equation}
Note that different choices of the preimage of $\mu_\alpha$ lead to different closures of $(S^3(U), \gamma(x,y))$. From (5.3), we know that $\phi(\lambda_U) = z \lambda_\alpha + y \mu_\alpha$, where $z = x$ if $y = 0$, $z = y$ is arbitrary if $y = 1$, and $zx \equiv 1 \pmod{y}$ in other cases. Again different choices of $z$ lead to different closures. From now on, we fix the value of $z$ as follows: $z = x$ if $y = 0,$
\( z = 0 \) if \( y = 1 \), and \( z \) is the minimal positive integer so that \( y|(xz - 1) \). Now, composing \( \phi \) with the inverse of the map \( \rho \) in (5.1), suppose
\[
\hat{Y} = Y(\alpha) \cup_{\phi \circ \rho^{-1}} S^1 \times D^2,
\]
where \( \phi \circ \rho^{-1} : \partial(S^1 \times D^2) \to \partial Y(\alpha) \) is a diffeomorphism such that
\[
\phi \circ \rho^{-1}([1] \times \partial D^2) = z\lambda_\alpha + y\mu_\alpha.
\]
Hence, \( \hat{Y} \) is obtained from \( Y \) by performing a \( y/z \) surgery and we also write \( \hat{Y} = \hat{Y}_{y/z} \).

**Lemma 5.2.** For any suture \( \gamma(x,y) \) on \( \partial S^3(U) \), we have
\[
\chi(\text{SHI}^\rho(S^3(U), \gamma(x,y))) = \pm y.
\]

**Proof.** First, we can focus on the closure \( \hat{Y} = \hat{Y}_{y/z} \), \( R = \Sigma, \omega \) as in (5.2). We need to compute the Euler characteristic of
\[
\text{SHI}^\rho(S^3(U), \gamma(x,y)) := I^\omega(\hat{Y}_{y/z}|\Sigma).
\]

If \( y = 0 \), then \( x = \pm 1 \), but \( (S^3(U), \gamma(\pm 1,0)) \) are both irreducible and non-taut. By Theorem 2.32, we know that
\[
\text{SHI}^\rho(S^3(U), \gamma(1,0)) = 0.
\]

If \( y = 1 \), then \( z = 0 \) and \( \hat{Y}_{1/0} = S^1 \times \Sigma \). By Axiom (A1-5), we have
\[
\chi(I^\omega(\hat{Y}_{1/0}|\Sigma)) = -1.
\]

If \( y > 1 \), we have \( y > z > 1 \). If \( z = 1 \), then we have an exact triangle from Axiom (A2)
\[
\begin{align*}
I^\omega(\hat{Y}_{y-1}|\Sigma) & \to I^\omega(\hat{Y}_y|\Sigma) \\
& \to I^\omega(\hat{Y}_{1/0}|\Sigma)
\end{align*}
\]
where the parity of the map \( f \) is odd and those of the rest two are even by Proposition 2.4. Hence we conclude by induction that
\[
\chi(I^\omega(\hat{Y}_y|\Sigma)) = -y.
\]

Finally, when \( y > z > 1 \), suppose the continued fraction of \(-y/z\) is
\[
\frac{-y}{z} = [a_0, \ldots, a_n] = a_0 - \frac{1}{a_1 - \frac{1}{\ddots - \frac{1}{a_n}}},
\]
where \( a_n \leq -2 \). Define
\[
\frac{-y'}{z'} = [a_0, \ldots, a_{n-1}] \quad \text{and} \quad \frac{-y''}{z''} = [a_0, \ldots, a_{n-1} + 1],
\]
where \( y', y'' \geq 0 \). From a basic property of continued fraction, we have
\[
y = y' + y'' \quad \text{and} \quad z = z' + z''.
\]
From Axiom (A2), there exists an exact triangle

\[
\begin{array}{ccc}
I^w(\tilde{Y}_{y'z'|\Sigma}) & \xrightarrow{f} & I^w(\tilde{Y}_{y'|\Sigma}) \\
\downarrow & & \downarrow \\
I^w(\tilde{Y}_{y'z'|\Sigma}) & \xrightarrow{g} & I^w(\tilde{Y}_{y'|\Sigma})
\end{array}
\]

where the parity of the map \( f \) is odd, and those of the rest two are even by Proposition 2.4 \( \square \)

**Remark 5.3.** It is worth mentioning that different papers have different normalizations for the canonical \( \mathbb{Z}_2 \)-grading. Our choice of normalization in Axiom (A3) is the same as in \([KM10a]\). In Lidman, Pinzón-Caicedo, and Scaduto’s setup \([LPCS20]\), they adapted another normalization and proved \( \chi(I^w(S^1 \times \Sigma|\Sigma)) = 1 \) for \( \Sigma \) of any genus that is at least one.

**Corollary 5.4.** Suppose \((Y', R', \omega')\) is a closure of \((S^3(U), \gamma(y, y'))\), then

\[ \chi(I(Y|R)) = \pm y. \]

**Proof.** This corollary follows directly from the fact that canonical maps from \( I^w(\tilde{Y}_1|\Sigma) \) to \( I^w(Y'|R') \) is a composition of cobordism maps and hence is homogeneous. \( \square \)

### 5.2. Sutured knot complements.

Suppose \( Y \) is a closed 3-manifold and \( K \subset Y \) is a null-homologous knot. Any Seifert surface \( S \) of \( K \) gives rise to a framing on \( \partial Y(K) \): the meridian \( \mu \) can be picked as the meridian of the solid torus \( N(K) \), and the longitude \( \lambda \) can be picked as \( S \cap \partial Y(K) \). The ‘half lives and half dies’ fact for 3-manifolds implies that the following map has a 1-dimensional image:

\[ \hat{\partial}_x : H_2(Y(K), \partial Y(K); \mathbb{Q}) \to H_1(\partial Y(K); \mathbb{Q}). \]

Hence any two Seifert surfaces lead to the same framing on \( \partial Y(K) \).

**Definition 5.5.** The framing \((\lambda, -\mu)\) defined as above is called the **canonical framing** of \((Y, K)\). With this canonical framing, let

\[ \gamma(x, y) = \gamma x\lambda + y\mu \subset \partial Y(K) \]

be the suture consisting of two disjoint simple closed curves representing \( \pm (x\lambda + y\mu) \).

Our goal in this subsection is to define a canonical \( \mathbb{Z}_2 \)-grading on \( \text{SHI}^g(Y(K), \gamma(x, y)) \) for any fixed large enough \( g \). Recall \( \text{SHI}^g(M, \gamma) \) is the projective transitive system formed by closures of \((M, \gamma)\) of a fixed genus \( g \). We first assign a \( \mathbb{Z}_2 \)-grading for any closure of \((Y(K), \gamma(x, y))\).

Suppose \((\tilde{Y}, R, \omega)\) is a closure of \((Y(K), \gamma(x, y))\). Then we can form a closure \((\tilde{Y}_U, R, \omega)\) of \((S^3(U), \gamma(x, y))\) by taking

\[ (5.4) \quad \tilde{Y}_U = \tilde{Y} \setminus (\text{int}(Y(K))) \cup S^3(U). \]

Here \( \text{id} \) is the diffeomorphism between toroidal boundaries, which respect the canonical framings on both boundaries.

**Definition 5.6.** The **modified \( \mathbb{Z}_2 \)-grading** on \( I^w(\tilde{Y}|R) \) is defined as follows.

1. If \( \chi(I^w(\tilde{Y}_U|R)) \) is negative, then the grading is defined by the canonical \( \mathbb{Z}_2 \)-grading on \( I^w(\tilde{Y}|R) \).
2. If \( \chi(I^w(\tilde{Y}_U|R)) \) is positive, then the grading is defined by switching the odd and even parts of \( I^w(\tilde{Y}|R) \) with the canonical \( \mathbb{Z}_2 \)-grading.
Suppose \( (\bar{Y}, R, \omega) \) and \( (\bar{Y}', R, \omega) \) are two closures of \((Y(K), \gamma_{(x,y)})\) so that \( \bar{Y}' \) is obtained from \( \bar{Y} \) by a Dehn surgery along a curve \( \beta \subset \bar{Y} \), which is disjoint from \( \text{int}(M) \), \( R \) and \( \omega \). Then there is a map
\[
F : \text{I}^\omega(\bar{Y} \mid R) \to \text{I}^\omega(\bar{Y}' \mid R)
\]
associated to the Dehn surgery along \( \beta \subset \bar{Y} \). Let \( (\bar{Y}_U, R, \omega) \) and \( (\bar{Y}'_U, R, \omega) \) be the closures of \((S^3(U), \gamma_{(x,y)})\) constructed as in \( \text{5.4} \). There is also a map
\[
F_U : \text{I}^\omega(\bar{Y}_U \mid R) \to \text{I}^\omega(\bar{Y}'_U \mid R)
\]
associated to the same Dehn surgery along \( \beta \subset \bar{Y}_U \). Then we have the following.

**Lemma 5.7.** The maps \( F \) and \( F_U \) have the same parity with respect to the canonical \( \mathbb{Z}_2 \)-gradings on corresponding instanton Floer homologies.

**Proof.** Note that \( H_1(S^3(U); \mathbb{Q}) \cong \mathbb{Q} \langle \mu_U \rangle \) and the map
\[
i^U_* : H_1(\partial S^3(U); \mathbb{Q}) \to H_1(S^3(U); \mathbb{Q})
\]
induced by the inclusion has a 1-dimensional kernel generated by \( \lambda_U \). For a null-homologous knot \( K \subset Y \), we know that the map
\[
i_* : H_1(\partial Y(K); \mathbb{Q}) \to H_1(Y(K); \mathbb{Q})
\]
induced by the inclusion has a 1-dimensional kernel generated by the longitude \( \lambda \) of \( K \) and has a 1-dimensional image generated by the meridian \( \mu \) of \( K \). Hence, from the Mayer-Vietoris sequence, we know that there is an injective map
\[
j : H_1(\bar{Y}_U; \mathbb{Q}) \to H_1(\bar{Y}; \mathbb{Q}),
\]
that sends \( [\mu_U] \) to \( [\mu] \) and sends every homology class in \( \bar{Y}_U \setminus S^3(U) = \bar{Y} \setminus Y(K) \) using the natural map
\[
i^U_* : H_1(\bar{Y} \setminus Y(K); \mathbb{Q}) \to H_1(\bar{Y}; \mathbb{Q}).
\]

Similarly, since \( \beta \cap \text{int}(Y(K)) = \emptyset \), we know that there is an injective map
\[
j^\beta : H_1(\bar{Y}_U(\beta); \mathbb{Q}) \to H_1(\bar{Y}(\beta); \mathbb{Q}),
\]
which fits into the following commutative diagram
\[
\begin{array}{ccc}
H_1(\partial \bar{Y}_U(\beta); \mathbb{Q}) & \xrightarrow{i^U_*} & H_1(\bar{Y}_U(\beta); \mathbb{Q}) \\
\downarrow & & \downarrow
\end{array}
\]
\[
\begin{array}{ccc}
H_1(\partial \bar{Y}(\beta); \mathbb{Q}) & \xrightarrow{i_*} & H_1(\bar{Y}(\beta); \mathbb{Q})
\end{array}
\]
where \( i_* \) and \( i^U_* \) are induced by natural inclusions. Hence we conclude, under the identification
\[H_1(\partial \bar{Y}_U(\beta); \mathbb{Q}) = H_1(\partial \bar{Y}(\beta); \mathbb{Q}),\]
two kernels are also identified:
\[\ker(i^U_*) = \ker(i_*).\]

Since \( F \) and \( F_U \) are associated to Dehn surgeries along \( \beta \) of the same slopes, we conclude from \text{2.4} that their parity must be the same.
Lemma 5.8. Suppose \((Y, R, \omega)\) and \((Y', R', \omega')\) are two different closures of \((Y(K), \gamma_{(x,y)})\) so that \(g(R) = g(R')\). There is a canonical isomorphism

\[ \Phi : I^\omega(Y|R) \cong I^\omega(Y'|R') \]

as in Definition 2.11. Then with respect to the modified \(\mathbb{Z}_2\)-grading as in Definition 5.6, the canonical map \(\Phi\) is grading preserving.

Proof. From the definition of \(\Phi\) and Axiom (A3-3), we know that \(\Phi\) is always homogeneous. For two closures \((Y, R, \omega)\) and \((Y', R', \omega')\) of \((Y(K), \gamma_{(x,y)})\), we can form two corresponding closures \((Y_U, R, \omega)\) and \((Y'_U, R, \omega')\) of \((S^3(U), \gamma_{(x,y)})\) as in (5.2), respectively. There is a canonical map

\[ \Phi_U : I^\omega(Y_U|R) \cong I^\omega(Y'_U|R'). \]

From Definition 5.6, the modified \(\mathbb{Z}_2\)-gradings on \(I^\omega(Y|R)\) and \(I^\omega(Y'|R')\) coincide if and only if the canonical \(\mathbb{Z}_2\)-gradings on \(I^\omega(Y_U|R)\) and \(I^\omega(Y'_U|R')\) coincide. The definition of the modified \(\mathbb{Z}_2\)-grading automatically makes \(\Phi_U\) even under the modified \(\mathbb{Z}_2\)-grading. Hence to show that \(\Phi\) is grading preserving, it suffices to show that \(\Phi\) and \(\Phi_U\) have the same parity under the modified \(\mathbb{Z}_2\)-grading.

From the construction of the canonical maps, there is a sequence of simple closed curves \(\beta_1, \ldots, \beta_n\) on \(R\), such that the map \(\Phi\) is the composition of cobordism maps induced by a diffeomorphism and the sequence of Dehn surgeries. Similarly, the map \(\Phi_U\) is the composition of the maps induced another diffeomorphism and the same sequence of Dehn surgeries on \(Y_U\). Since the surgery curves are all on \(R\) and disjoint from \(\text{int}(Y(K))\), cobordism maps induced by diffeomorphisms are always with even degrees, i.e. preserving the \(\mathbb{Z}_2\)-grading. For Dehn surgeries along \(\beta_i\), we can apply Lemma 5.7 and then finish the proof. \(\Box\)

Definition 5.9. Suppose \((Y(K), \gamma_{(x,y)})\) is the balanced sutured manifold constructed as before and suppose \(g\) is the fixed large enough genus of closures. By Lemma 5.8, we can define the canonical \(\mathbb{Z}_2\)-grading on \(\text{SHI}^g(Y(K), \gamma_{(x,y)})\) by the modified \(\mathbb{Z}_2\)-grading on the closures. In particular, there is a canonical \(\mathbb{Z}_2\)-grading on \(\text{KH}^g(Y, K)\).

Proposition 5.10. The canonical \(\mathbb{Z}_2\)-grading on \(\text{SHI}^g(Y(K), \gamma_{(x,y)})\) is independent of the large enough genus \(g\).

Proof. We need to compare the \(\mathbb{Z}_2\)-grading for closures of different genera. First we deal with the case of unknot. As in Subsection 5.1, we can construct a standard closure \((Y_{y/z}, \Sigma)\) for \((Y(K), \gamma_{(x,y)})\). Here, the genus of \(\Sigma\) can be arbitrary. To specify the genus, in the proof of this corollary, we temporarily write \((Y_{y/z}, \Sigma)\) as \((Y_{y/z}^g, \Sigma_g)\). In \([BSL]\), the canonical map

\[ \phi_{g,g+1} : I^\omega(Y_{y/z}^g, \Sigma_g) \to I^\omega(Y_{y/z}^{g+1}, \Sigma_{g+1}) \]

is constructed as follows: recall \(\alpha \subset \Sigma_g\) is a non-separating simple closed curve, and

\[ Y_{y/z}^g = Y(K) \cup (S^1 \times \Sigma_g) \setminus \Sigma(\alpha). \]

Let \(\beta \subset \Sigma_g\) be another simple closed curve so that \(\alpha \cap \beta = \emptyset\). Take a curve \(\theta \subset \Sigma_2\) be non-separating simple closed curve as well. Then we can form \((Y_{y/z}^{g+1}, \Sigma_{g+1})\) from \((Y_{y/z}^g, \Sigma_g)\) and \((S^1 \times \Sigma_2, \Sigma_2)\) by cutting them open along \(S^1 \times \beta\) and \(S^1 \times \theta\) respectively, and then glue the two pieces together along toroidal boundaries by the identifying the \(S^1\) factor and \(\beta = \theta\). Then, as in \([KM10b]\), there is a cobordism \(W_{g,g+1}\) from \((Y_{y/z}^g, \Sigma_g)\) and \((S^1 \times \Sigma_2, \Sigma_2)\) to \((Y_{y/z}^{g+1}, \Sigma_{g+1})\), known as the Floer excision cobordism. In the proof of \([LPCS20]\) Proposition 3.6 and \([KM10a]\) Lemma 3.3, the degree of
the cobordism induced by cobordisms constructed in the same way as \( W^{g,g+1} \) has been computed explicitly. By a similar computation, we know that the canonical map \( \Phi^{g,g+1} \) preserves the modified \( \mathbb{Z}_2 \)-grading (Note by the above argument, the modified \( \mathbb{Z}_2 \)-grading for \( \bar{Y}_{g/2} \)) is the same as the canonical grading). For any two closures of \( (Y(K), \gamma_{(x,y)}) \), as in [BS15], the canonical maps are constructed by composing the maps induced by some \( W^{g,g+1} \) and canonical maps for closures of the same genera. Since both types of maps are grading preserving, we conclude that any canonical map preserves the modified \( \mathbb{Z}_2 \)-grading.

\[ \square \]

**Remark 5.11.** The proof of Proposition 5.10 does not apply to other Floer-type theories \( \mathcal{H} \) because we need to use Floer’s excision theorem along a surface of genus one.

### 5.3. Computations and applications.

In this subsection, we do some calculations based on techniques introduced before.

At first, we deal with bypass exact triangles. Suppose \( y_3/x_3 \) is a surgery slope with \( y_3 \geq 0 \). According to Honda [Hon00], there are two basic bypasses on the balanced sutured manifold \( (Y(K), \gamma_{(x_3,y_3)}) \), whose arcs are depicted as in Figure 17. The sutures involved in the bypass triangles were described explicitly in Honda [Hon00].

![Figure 17. Bypass arcs on \( \gamma_{(1,-1)} \).](image)

**Definition 5.12.** For a surgery slope \( y_1/x_1 \) with \( y_1 \geq 0 \), suppose its continued fraction is

\[
\frac{y_1}{x_1} = \left[a_0, a_1, \ldots, a_n\right] = a_0 - \frac{1}{a_1 - \frac{1}{\ddots - \frac{1}{a_n}}}.
\]

where \( a_i \leq -2 \). If \( y_1 > -x_1 > 0 \), let

\[
\frac{y_2}{x_2} = \left[a_0, \ldots, a_{n-1}\right] \quad \text{and} \quad \frac{y_3}{x_3} = \left[a_0, \ldots, a_n + 1\right].
\]

If \( -x_1 > y_1 > 0 \), we do the same thing for \( x_1/(-y_1) \). If \( y_1 > x_1 > 0 \), we do the same thing for \( y_1/(-x_1) \). If \( x_1 > y_1 > 0 \), we do the same thing for \( x_1/(-y_1) \). If \( y_1/x_1 = 1/-1 \), then \( y_2/x_2 = 0/1 \) and \( y_3/x_3 = 1/(-1) \). If \( y_1/x_1 = 0/1 \), let \( y_2/x_2 = 1/(-1) \) and \( y_3/x_3 = 0/1 \). We always require that \( y_2 \geq 0 \) and \( y_3 \geq 0 \).

**Remark 5.13.** It is straightforward to use induction to verify that for \( y_1 > -x_1 > 0 \),

\[
x_1 = x_2 + x_3, \quad \text{and} \quad y_1 = y_2 + y_3.
\]
Then the bypass exact triangle in Theorem 2.19 becomes the following.

**Proposition 5.14.** Suppose $K \subset Y$ is a null-homologous knot, and suppose the surgery slopes $y_i/x_i$ for $i = 1, 2, 3$ are defined as in Definition 5.12. Suppose $\psi^+_{*, *}$ and $\psi^-_{*, *}$ are from two different bypasses, where $*$ means the corresponding slope. Then there are two exact triangles about $\psi^+_{*, *}$ and $\psi^-_{*, *}$, respectively.

As stated in Proposition 2.20, the bypass maps $\psi_1$, $\psi_2$, and $\psi_3$ are induced by some cobordism maps. Then we have the following.

**Lemma 5.15.** Suppose $g$ is a large enough integer and suppose $y_i/x_i$ for $i = 1, 2, 3$ is from Definition 5.12. Suppose further

$$x_1 = x_2 + x_3$$ and $$y_1 = y_2 + y_3.$$ With respect to the canonical $\mathbb{Z}_2$-grading on $\text{SHI}^g$ in Definition 5.9, the parity of the map $\psi_2$ is odd and those of the rest two are even. As a consequence,

$$\chi(\text{SHI}^g(-Y(K), -\gamma(x_1, y_1))) = \chi(\text{SHI}^g(-Y(K), -\gamma(x_2, y_2))) + \chi(\text{SHI}^g(-Y(K), -\gamma(x_3, y_3))).$$

**Proof.** As in Proposition 2.20, we can fix a large enough $g$ so that for $i = 1, 2, 3$, there are closures $(\bar{Y}_i, R, \omega)$ for $(-Y(K), -\gamma(x_i, y_i))$ of genus $g$, and the bypass maps $\psi_1$, $\psi_2$, and $\psi_3$ have the same $\mathbb{Z}_2$ degree because the maps induced by Dehn surgeries along three curves $\zeta_1$, $\zeta_2$, and $\zeta_3$ in corresponding closures $\bar{Y}_i, \text{int}(Y(K))$. Since we only care about the $\mathbb{Z}_2$ degrees of maps, in a slight abuse of notation, we do not distinguish the bypass map and the map induced by Dehn surgery.

For $i = 1, 2, 3$, we can form corresponding closures $(\bar{Y}_i^U, R, \omega)$ as in (5.2) so that the curves $\zeta_1$, $\zeta_2$, and $\zeta_3$ still lie in closures. Moreover, suitable surgeries along these curves induces an exact triangle

As in the proof of Lemma 5.8, with the help of Lemma 5.7, it suffices to check that the parities of maps $\psi_1^U$, $\psi_2^U$, and $\psi_3^U$ are odd or even as claimed, with respect to the canonical $\mathbb{Z}_2$-grading on $\text{SHI}^g$ from Definition 5.9.

For the case of the unknot, the argument becomes straightforward: from Definition 5.6 and Lemma 5.2, we know that for any $y > 0$,

$$\chi(\text{SHI}^g(-S^3(U), -\gamma(x, y))) = -y$$

Then the equation $y_1 = y_2 + y_3$ implies that

$$\chi(\text{SHI}^g(-S^3(U), -\gamma(x_1, y_1))) = \chi(\text{SHI}^g(-S^3(U), -\gamma(x_2, y_2))) + \chi(\text{SHI}^g(-S^3(U), -\gamma(x_3, y_3))).$$

Note that the maps $\psi_i^U$ for $i = 1, 2, 3$ are coming from a real surgery exact triangle as in Proposition 2.20, while the $\mathbb{Z}_2$-gradings on $\text{SHI}^g$ could possibly be shifted due to the normalization
in Definition 5.6 and the surgery along curves \( \eta_1 \) and \( \eta_2 \) as in Proposition 2.20. Hence they still satisfy the hypothesis of Lemma 2.5. Thus, we conclude that the parity of \( \psi^g_{x/y} \) is odd and those of the other two are even. Similarly, the parity of \( \psi_2 \) is odd and those of the other two are even, and we have

\[
\chi(\text{SHI}^g(-Y(K), -\gamma(x_1, y_1))) = \chi(\text{SHI}^g(-Y(K), -\gamma(x_2, y_2))) + \chi(\text{SHI}^g(-Y(K), -\gamma(x_3, y_3))).
\]

Let \( Y \) be a closed 3-manifold and let \( K \subset Y \) be a null-homologous knot. Suppose \( S \) is a minimal genus Seifert surface of \( K \). Its genus is always denoted by \( g(S) \), which is distinguished with \( g \), the fixed genus of closures. We refer \cite{LY20} Section 4 for the definitions of sutures \( \Gamma_n, \Gamma_u(y/x) \), the admissible surface with stabilization \( S^r \), the bypass maps \( \psi^*_+, \psi^*_- \), and numbers \( i^*_{\text{max}}, i^*_{\text{min}} \). To simplify our notation, we write

\[
\chi^g_{y/x}(-Y, K, i) = \chi(\text{SHI}^g(-Y(K), -\gamma(x, y), S^r, i))
\]

where the Euler characteristic is with respect to the canonical \( \mathbb{Z}_2 \)-grading on \( \text{SHI}^g \) as in Definition 5.9. We write

\[
\chi^g_{y/x}(-Y, K, i) = \sum_{x \in \mathbb{Z}} \chi^g_{y/x}(-Y, K, i)
\]

When \( |x| = 1 \), we write \( y/x \) as an integer. Also, we write

\[
\chi^g_{y/x}(-Y, K, i) = \chi^g_{1/0}(-Y, K, i)
\]

to specify the meridional suture.

**Lemma 5.16.** Suppose \( Y \) is a closed oriented 3-manifold, and \( K \subset Y \) is a null-homologous knot. For \( g \in \mathbb{Z} \) large enough and any \( i \in \mathbb{Z} \), we have

\[
\chi^g_{1/0}(-Y, K, i) = \chi^g_{1/0}(-Y, K, i) \quad \text{and} \quad \chi^g_{0/1}(-Y, K, i) = 0.
\]

**Proof.** From \cite{LY20} Proposition 4.16, we have the following two bypass exact triangles:

\[
\begin{align*}
\text{SHI}^g(-Y(K), -\Gamma_0, S^r, i) & \xrightarrow{\psi^g_{0,1}} \text{SHI}^g(-Y(K), -\Gamma_1, S^r, i) \\
& \xleftarrow{\psi^g_{1,0}} \text{SHI}^g(-Y(K), -\Gamma_0, S^r, i)
\end{align*}
\]

and

\[
\begin{align*}
\text{SHI}^g(-Y(K), -\Gamma_0, S^r, i + 1) & \xrightarrow{\psi^g_{0,1}} \text{SHI}^g(-Y(K), -\Gamma_1, S^r, i) \\
& \xleftarrow{\psi^g_{1,0}} \text{SHI}^g(-Y(K), -\Gamma_0, S^r, i)
\end{align*}
\]

Hence we obtain the following two equations from Lemma 5.15

\[
\begin{align*}
\chi^g_{1/0}(-Y, K, i) &= \chi^g_{0/1}(-Y, K, i) + \chi^g_{0/1}(-Y, K, i) \\
\chi^g_{1/0}(-Y, K, i) &= \chi^g_{0/1}(-Y, K, i) + \chi^g_{0/1}(-Y, K, i)
\end{align*}
\]

By Axiom (A1-4), for \( i > g(S) \), we have

\[
\text{SHI}^g(-Y(K), -\Gamma_0, S^r, i) = 0.
\]
Hence we conclude by (5.5) and (5.6) that
\[ \chi^q_{gY}(-Y, K, g(S)) = \chi_{\mu}^q(-Y, K, g(S)) \text{ and } \chi_{\mu}^q(-Y, K, g(S)) = 0. \]

The lemma follows from the induction on the grading \( i \).

**Lemma 5.17.** Suppose \( Y \) is a closed oriented 3-manifold, and \( K \subset Y \) is a null-homologous knot. For the suture \( \gamma(x, y) \) with \( y > 0 \), we know that
\[ \chi^q_{y/x}(-Y, K, i) = \sum_{j=0}^{y-1} \chi_{\mu}^q(-Y, K, i - i_{\max} + i_{\mu} + j). \]

**Proof.** We only prove the case when \( x < 0 \). The other case is similar. First, if \( x = 1 \), then we have a bypass exact triangle (in this case we write \( y = n \))
\[
\begin{array}{c}
\text{SHI}^q(-Y(K), -\Gamma_n, S^\tau, i) \\
\xrightarrow[\psi_{-n}]{} \text{SHI}^q(-Y(K), -\Gamma_{n+1}, S^\tau, i) \\
\xleftarrow[\psi_{-n+1}]{} \text{SHI}^q(-Y(K), -\Gamma_{\mu}, S^\tau, i + 1)
\end{array}
\]
Hence, we can apply Lemma 5.15, Lemma 5.16, and the induction to conclude that
\[ \chi^q_{y/x}(-Y, K, i) = \sum_{j=0}^{n-1} \chi_{\mu}^q(-Y, K, i - i_{\max} + i_{\mu} + j). \]
If \( x > 1 \), we can use the continued fraction description of \( y/x \) and apply an induction in the same spirit as in the proof of Lemma 5.2. □

**Corollary 5.18.** Suppose \( Y \) is a closed oriented 3-manifold, and \( K \subset Y \) is a null-homologous knot. For the suture \( \gamma(x, y) \) where \( y > 2g(S) \), and for any \( i \in \mathbb{Z} \) so that
\[ i_{\max}^y - 2g(S) \geq i \geq i_{\min}^y + 2g(S), \]
we know that
\[ \chi^q_{y/x}(-Y, K, i) = \chi^q_Y(-Y, K). \]

**Proof.** The corollary follows immediately from Lemma 5.17 and the fact that there are only \((2g(S)+1)\) gradings with nontrivial elements for \( \text{SHI}^q(-Y(K), -\Gamma_{\mu}, S^\tau) \). □

**Lemma 5.19.** Suppose \( Y \) is a closed oriented 3-manifold, and \( K \subset Y \) is a null-homologous knot. Then we have
\[ \chi_{\mu}^q(-Y, K) = \pm \chi(I^q(-Y)). \]

**Proof.** From Lemma 5.17 we know that for any \( n \in \mathbb{Z}_{>0} \), we have
\[ \chi_{\mu}^q(-Y, K) = n \cdot \chi_{\mu}^q(-Y, K). \]
From [LY20, Lemma 4.11], we know that there is an exact triangle
\[
\begin{array}{c}
\text{SHI}^q(-Y(K), -\Gamma_n) \\
\xrightarrow{I(-Y)} \text{SHI}^q(-Y(K), -\Gamma_{n+1})
\end{array}
\]
Hence, by Lemma 2.5 we know that there is a proper sign assignment for all $n$ so that 
\[ \pm \chi_n^g(-Y, K) \pm \chi_{n+1}^g(-Y, K) \pm \chi(I^2(Y)) = 0. \]
Hence the only possibilities are 
\[ \chi(I^2(Y)) = \pm \chi_0^g(-Y, K). \]
\[ \Box \]

**Proof of Proposition 1.21**. It is an immediate corollary following Corollary 5.18, Lemma 5.19 and the definition of the decomposition from [LY20, Section 4.3].

For a knot $K$ in $S^3$, we can actually fix the sign ambiguity coming from different choices of the fixed genus of the closures.

**Lemma 5.20.** For any knot $K \subset S^3$ and any positive integer $g$, we have 
\[ \chi_0^g(-S^3, K) = -1. \]

**Proof.** Since we adapt the normalization from Kronheimer and Mrowka [KM10a, Section 2.6], we can directly apply the results from them. In particular, for any knot $K$, in [KM10a, Section 2.4], a preferred closure $(\bar{Y}_1, \Sigma_1, \omega_1)$ of $(-S^3(K), -\Gamma_\mu)$ with $g(\Sigma_1) = 1$ is chosen. Then they proved that 
\[ \chi(I^{-1}(\bar{Y}_1|\Sigma_1)) = -\Delta_K(1) = -1. \]

Note that this coincide with our choice of modified $\mathbb{Z}_2$-grading: when the Euler characteristic is negative, we do not perform any shift.

The case $g = 2$ has already been studied in the proof of [KM10a, Lemma 3.3]: another preferred closure $(\bar{Y}_2, \Sigma_2, \omega_2)$ with $g(\Sigma_2) = 2$ for $(-S^3(K), -\Gamma_\mu)$ is constructed, and there is a cobordism $W_1$ from $\bar{Y}_1 \cup S^3 \times \Sigma_2$ to $\bar{Y}_2$ coming from Floer’s excision theorem. The canonical generator of $I^2(S^1 \times \Sigma_2|\Sigma_2)$ is proved to be at the odd grading (c.f. [LPCS20, Lemma 3.8], though the normalization of the canonical $\mathbb{Z}_2$-grading is different). Moreover, the degree of the cobordism map $W_1$ is odd (c.f. [LPCS20, Proposition 3.6]).

For general $g$, it is straightforward to generalize the above construction for $\bar{Y}_1$ and $\bar{Y}_2$ to $\bar{Y}_g$ and $\bar{Y}_{g+1}$. There is a similar cobordism $W_g$ from $\bar{Y}_g \cup S^3 \times \Sigma_2$ to $\bar{Y}_{g+1}$, the degree of which can be computed easily to be odd. Hence by induction we conclude that for all $g$, 
\[ \chi_0^g(-S^3, K) = -1. \]
\[ \Box \]

By Lemma 5.20, we can identify $\chi_0^g(-S^3, K)$ for all large enough $g$, we simply write $\chi_\mu(-S^3, K) = \chi_\mu^0(-S^3, K)$ instead. Applying Lemma 5.17, we know that for any $g$ large enough and $y > 0$, 
\[ \chi_{y/2}^g(-S^3, K) = -y. \]

Similarly, we simply write $\chi_{y/z}^g(-S^3, K)$ instead.

Finally, we consider the projectively system $\text{SHI}(M, \gamma)$ for a balanced sutured manifold $(M, \gamma)$ defined in [BS15], which is independent of the choice of the genus of the closures. The isomorphism class of $\text{SHI}(M, \gamma)$ and $\text{SHI}^g(M, \gamma)$ are the same. Similar to $\text{SHI}^g(M, \gamma)$, it has a decomposition associated to an admissible surface $S \subset (M, \gamma)$.

**Definition 5.21.** Suppose $(M, \gamma)$ is a balanced sutured manifold and $S$ is an admissible surface in $(M, \gamma)$. For any $i, j \in \mathbb{Z}$, define 
\[ \text{SHI}(M, \gamma, S, i)[j] = \text{SHI}(M, \gamma, S, i - j). \]
In [Li19, Section 5], the first author constructed a minus version of the instanton knot homology via the direct system

$$\cdots \to \text{SHI}(-S^3(K, \Gamma_n, S^\tau)[g(K) - i^\tau_n] \xrightarrow{\psi_{-n+1}^n} \text{SHI}(-S^3(K, \Gamma_{n+1}, S^\tau)[g(K) - i^\tau_{n+1}] \to \cdots$$

and define $\text{KHI}^-(S^3, K)$ to be the direct limit of (5.7). All $\psi_{-n+1}^n$ are grading preserving after shifting, so there is a well-defined $\mathbb{Z}$-grading (the Alexander grading) on $\text{KHI}^-(S^3, K)$, which we write as

$$\text{KHI}^-(S^3, K, i).$$

By [Li19, Corollary 2.20], there is a commutative diagram

$$\begin{array}{ccc}
\text{SHI}(-S^3(K, \Gamma_n, S^\tau)[g(K) - i^\tau_n] & \xrightarrow{\psi_{-n+1}^n} & \text{SHI}(-S^3(K, \Gamma_{n+1}, S^\tau)[g(K) - i^\tau_{n+1}] \\
\psi_{-n+1}^n & \downarrow & \psi_{-n+1}^{n+1} \\
\text{SHI}(-S^3(K, \Gamma_{n+1}, S^\tau)[g(K) - i^\tau_{n+1}] & \xrightarrow{\psi_{-n+1}^{n+1}} & \text{SHI}(-S^3(K, \Gamma_{n+2}, S^\tau)[g(K) - i^\tau_{n+2}] \\
\end{array}$$

Hence the maps $\{\psi_{-n+1}^n\}$ induces an map $U$ on $\text{KHI}^-(S^3, K)$.

**Proof of Proposition 1.23.** From Lemma 5.15, the parity of maps $\psi_{-n+1}^n$ are all even, hence there is a well-defined $\mathbb{Z}_2$-grading on $\text{KHI}^-(S^3, K)$. Again from Lemma 5.15, we know that the parity of the map $U$ is even, i.e., preserving the $\mathbb{Z}_2$-grading on $\text{KHI}^-(S^3, K)$. Finally, we can apply Lemma 5.17 and the fact

$$\chi(\text{KHI}^g(S^3, K)) = -\Delta_K(t)$$

to conclude the desired formula. Note that by our normalization, the sign is negative. $\square$
