Hemodialysis catheter-related infection caused by 

**Pannonibacter phragmitetus:** a rare case report in China

**Pannonibacter phragmitetus** (*P. phragmitetus*) is rarely related with human disease. We reported a case of catheter-related infection caused by *P. phragmitetus* in a 68-year-old woman on hemodialysis. The patient developed recurrent fever during hemodialysis and blood cultures were positive for *P. phragmitetus*. The patient’s body temperature returned to normal after intravenous cefoperazone/sulbactam treatment, and the hemodialysis catheter was locked with gentamicin and urokinase. The potential anti-infective treatment against *P. phragmitetus* was discussed.

**KEYWORDS**

*Pannonibacter phragmitetus*, hemodialysis, catheter infection, recurrent fever, anti-infective treatment

**Introduction**

*Pannonibacter phragmitetus* (*P. phragmitetus*) is a gram-negative rod, which is recognized from a Hungarian soda lake in 2003 (Borsodi et al., 2003). *P. phragmitetus* is commonly applied to environmental pollution control due to its ability to remove nitrogen and metals in water and soil (Bai et al., 2019; Chai et al., 2019; Wang et al., 2019; Liao et al., 2020; Saravanan et al., 2021). Although it was first identified as *Achromobacter* groups B and E from human blood (Holmes et al., 1990; Holmes et al., 1993; Holmes et al., 2006), little is known about its pathogenicity. After searching in PubMed and Web of Science, we found only 4 cases of infection caused by *P. phragmitetus*: one case of late replacement valve endocarditis (McKinley et al., 1990), one case of recurrent septicemia (Jenks and Shaw, 1997), one case of liver abscess (Wang et al., 2017), and one case of
bacteremia (Gallardo et al., 2020). Here, we presented probably the first case of hemodialysis catheter infection caused by *P. phragmitetus* in China.

**Case presentation**

A 68-year-old woman with end-stage renal disease was admitted to our hospital for hemodialysis on September 16, 2021. The patient had a history of left kidney cyst, atrophy of both kidneys, chronic kidney disease, obstructive pulmonary disease, and hypertension. A rectal resection was performed in 2002. Her normal medication consisted of nifedipine (20 mg, bid), benazepril (10 mg, bid) and terazosin (2 mg, tid). Since January 19, 2021, the patient started hemodialysis three times a week via a catheter in the right internal jugular vein at a local hospital. On August 17, the patient had chills during hemodialysis. After returning home, she developed fever and sweating with a body temperature of 39.1°C. Her body temperature returned to normal after she received diclofenac and anti-infective treatment. On September 1, she became febrile again during hemodialysis. She was hospitalized at the local hospital for 10 days and she was recovered after receiving anti-infective therapy. On September 13, the patient developed chills, fever and sweating again with a body temperature of 38.6°C during hemodialysis. Her body temperature returned to normal after physical cooling.

Upon admission, the patients’ body temperature was 36.9°C, pulse rate was 82 beats/min, respiratory rate was 18 breaths/min, and blood pressure was 200/110 mmHg. Laboratory tests (see **Table 1**) showed impaired kidney function (CO2 21.4 mmol/L, creatinine 958.3 μmol/L, uric acid 460 μmol/L, BUN 23.2mmol/L), anemia (RBC 3.29×10^{12}/L, Hb 102 g/L), vitamin D deficiency (28.11 nmol/L), and hyperparathyroidism (PTH 226.1 pg/mL).

On the next day of admission, the patient developed fever during hemodialysis, and she was treated with intravenous demethylvancomycin (400 mg, qd). A pair of venous blood samples were collected prior to antimicrobial therapy, as well as a pair of blood sample drawn from the catheter. Aerobic blood cultures were positive after 2 days of incubation (48 h 25 min). A gram staining revealed gram-negative rods. Positive cultures were then transferred to Columbia blood agar plates, MacConkey agar plates, chocolate agar plates and Sabouraud’s agar plates at 35°C, and Sabouraud’s agar plates at 28°C. After incubation overnight, *P. phragmitetus* (Figure 1) was identified by matrix-assisted laser desorption ionization/time of flight mass spectrometry (LVD MALDI Biotyper System, Bruker Daltonik GmbH, Germany). *P. phragmitetus* was also verified by DNA sequencing (Supplementary Figure 1 and Data Sheet 1), using bacterial 16S rDNA primers (forward primer: 5’-AGTTTGATCMTGCTCAG-3’, reverse primer: 5’-GTTACCTTGTTACGACTT-3’). Antimicrobial susceptibility test (AST) was performed by the Kirby-Bauer disc diffusion method (Thermo Fisher Scientific, USA). The minimum inhibitory concentration (MIC) of *P. phragmitetus* for antibiotics were determined by BD Phoenix 100 system using NMIC/ID-4 susceptibility panels (**Table 2**). *P. phragmitetus* was sensitive to cefoxitin, imipenem, meropenem, amikacin, gentamicin, tetracycline, minocycline, ciprofloxacin, levofloxacin, chloramphenicol, but resistant against penicillin, ampicillin, piperacillin, piperacillin/tazobactam, aztreonam, trimethoprim/sulfamethoxazole, vancomycin, teicoplanin, clindamycin and linezolid amine. The patient was then changed to intravenous cefoperazone/sulbactam (500mg/2g/day).

**Table 1** Abnormal diagnostic results.

| Parameter         | Values | Normal range |
|-------------------|--------|--------------|
| RBC (×10^{12}/L) | 3.29   | 3.8~5.1      |
| Hb (g/L)         | 102    | 115~150      |
| HCT (%)          | 31.1   | 35~45        |
| CO₂ (mmol/L)     | 21.4   | 22~29        |
| Creatinine (μmol/L) | 958.3 | 41~81       |
| Uric acid (μmol/L) | 460   | 155~357      |
| BUN (mmol/L)     | 23.2   | 2.76~8.07    |
| AST (U/L)        | 11     | 13~35        |
| Calcium (mmol/L) | 2.02   | 2.2~2.55     |
| Phosphorus (mmol/L) | 1.59 | 0.85~1.51 |
| PTH (pg/mL)      | 226.1  | 12~88        |
| Vitamin D (nmol/L) | 28.11 | >75          |
| PCT (ng/ml)      | 1.04   | <0.46        |

RBC, red blood cell; Hb, Hemoglobin; HCT, Hematocrit; BUN, blood urea nitrogen; AST (aspartate aminotransferase); PTH, parathyroid hormone; PCT, procalcitonin.
500mg, bid) treatment. The hemodialysis catheter was locked with gentamicin (1.8×10^4 IU) and urokinase (1×10^5 IU).

Although clinical results were improved, but blood tests still showed a sign of infection (PCT 1.04 ng/ml, see Table 1). However, the patient refused to replace the hemodialysis catheter. On September 23, the patient was discharged from our hospital with treatment on nifedipine (20 mg, bid), benazepril (10 mg, bid), terazosin (2 mg, tid) and cefdinir (100 mg, tid). The patient underwent regular hemodialysis at the local hospital and developed no fever in the following 3 months (the patient’s medical timeline was shown in Figure 2).

**Discussion**

The first case of infection caused by *P. phragmitetus* was reported in a male patient who developed a low-grade fever in 1988 (McKinley et al., 1990). The patient underwent pulmonary autograft replacement in 1987 and *P. phragmitetus* was probably introduced during the previous surgery. In 1997, a male patient appeared fever after urinary catheterization, and then *P. phragmitetus* was identified in blood cultures (Jenks and Shaw, 1997). The patient had clinically important improvement after antibiotic therapy and removal of the catheter, but the patient

| Antimicrobial agent                              | MIC (µg/ml) | Interpretation |

developed fever again after recatheterization. The infection of *P. phragmitetus* was thought to be caused by insertion of the urinary catheter. In 2017, a male patient with liver abscess was diagnosed with *P. phragmitetus*. However, *P. phragmitetus* was only identified from blood cultures, but not from abscess fluid (Wang et al., 2017).

The first case of bacteriemia caused by *P. phragmitetus* in a hemodialysis patient was reported in 2020 (Gallardo et al., 2020). A male patient started hemodialysis due to impaired kidney function in Spain. After one month and a half, the patient made a trip to Cuba and did his regular hemodialysis at a local hospital. When he returned to Spain and continued hemodialysis, he developed fever during the session. The infection of *P. phragmitetus* was probably introduced during his stay in Cuba.

Highly like the case described in 2020, we reported the first hemodialysis related infection caused by *P. phragmitetus* in China. Fever occurred 4 times during or after hemodialysis in our case. However, the patient is also not engaged in environmental pollution treatment, and there is no lake near her house. Since 2022, the patient has been undergoing hemodialysis at our hospital, and there is currently no sign of fever or infection. Therefore, we speculate that *P. phragmitetus* was probably induced via the catheter during her regular hemodialysis at her local hospital.

Among total 5 cases of *P. phragmitetus* infection, fever appeared in 4 cases, and catheter-related infection (CRI) was suspected to be involved in 3 cases (Table 3). CRI is a common but terrified complication in hemodialysis patients (Labriola, 2019). Sepsis accounts for 6.5% of deaths for patients receiving hemodialysis in USA (System USRD., 2021). Genomic sequencing showed *P. phragmitetus* is multidrug-resistant (Zhou et al., 2017), but there is no standard treatment against *P. phragmitetus*. Combining AST results from literatures and the present case, imipenem, amikacin, ciprofloxacin, and gentamicin would be ideal options for anti-infective monotherapy or combination therapy.
