To the Editor: Human babesiosis caused by *Babesia divergens*, a zoono-otic pathogen of bovines in Europe, is an emerging tickborne disease [1]. In the United States, a closely related *Babesia* sp. was identified in persons in Missouri and Kentucky and in eastern cottontail rabbits (*Sylvilagus floridanus*) on Nantucket Island, Massachusetts (2–5). We report that sika deer (*Cervus nippon*) in Japan also carry parasites genetically closely related to *B. divergens*.

During November 2007–February 2008 and November 2008–February 2009, we collected blood samples from 96 wild sika deer throughout Japan. We purified DNA from the blood, which had been stored in a freezer, by phenol/chloroform extraction and performed nested PCR for *B. divergens 18S rRNA* (rDNA), chaperonin-containing T-complex protein 1 eta subunit (*CCT7*, formerly described as *CCTη*) (6), and *β-tubulin* (7) genes. Primers for rDNA were designed from the sequences of related *Babesia* spp. (GenBank accession nos. U16370, U16369, and AY046575): dv101F (5′-ACAA; CCTη) than those for heterogeneous (98.7%–99.9% identity) sequences of related *Babesia* species. In addition, 2 divergent sequences (GenBank accession nos. KC465977 and AB861504–5) and 5 identical sequences (GenBank accession nos. KC465977 and AB861504–5) (99.7%–100% identity). The 5 identical sequences varied in only 1 of 909 bp from *B. divergens* rDNA from an *Ixodes persulcatus* tick in Russia [GenBank accession no. GU057385] (8).

*β-tubulin* (900 bp) was also amplified from the 12 *Babesia* rDNA–positive samples. Ten of the sequences consisted of 3 sequence variants (99.9% identity; GenBank accession nos. KC465973–7 and AB857845–6) and 5 identical sequences (GenBank accession nos. KC465973–7 and AB857845–6) were more divergent sequences (GenBank accession nos. KC465968/AB861508–14). The 2 divergent sequences produced similar topology and high bootstrap support (Figure, panel B). However, the limited number of relevant *β-tubulin* sequences precludes conclusions regarding the phylogeny of *Babesia* parasites. A *CCT7* phylogenetic tree was not generated because of the paucity of sequences. Overall, the phylogenies suggest that *B. divergens*– and *B. capreoli*–related parasites are found worldwide in temperate zones of the Northern Hemisphere, including Europe (1), the United States (2–5), Russia (8), and Japan.

We also generated a phylogenetic tree of *β-tubulin* sequences (900 bp), which produced similar topology and high bootstrap support (Figure, panel B). However, the limited number of relevant *β-tubulin* sequences precludes conclusions regarding the phylogeny of *Babesia* parasites. A *CCT7* phylogenetic tree was not generated because of the paucity of sequences. Overall, the phylogenies suggest that *B. divergens*– and *B. capreoli*–related parasites are found worldwide in temperate zones of the Northern Hemisphere, including Europe (1), the United States (2–5), Russia (8), and Japan.

We showed the presence of *B. divergens*–like rDNA, *β-tubulin*, and *CCT7* genes in sika deer from different Japanese prefectures, confirming the presence of this parasite in Japan. *B. capreoli*, which is serologically indistinguishable from *B. divergens*, was previously reported in sika deer (10). However, no molecular data for the *B. capreoli* isolate exist, so no
conclusion may be drawn regarding its relationship to the B. divergens–like parasites from sika deer in our study. There is an overabundance of wild sika deer in Japan because these animals easily adapt to a variety of climates, vegetation, and geography. Increased human exposure to deer habitats increases the risk of exposure to tickborne zoonoses, such as those caused by Babesia spp. In humans, infections caused by B. divergens and B. divergens–like parasites can be life threatening; fatality rates of 42% and 33% have been reported in infected asplenic patients in Europe and the United States, respectively (1–3).

The findings from our study emphasize the need for increased clinical awareness of babesiosis in Japan and globally. They also emphasize the need for the swift diagnosis of suspected cases and prompt treatment of confirmed cases, especially in asplenic patients at high risk for the potentially deadly consequences of babesiosis.

Acknowledgments

We are grateful to Danny H.-K. Jokl for his critical reading of the manuscript. We thank Jeremy Gray for providing genomic DNA of B. divergens MRNK and Marek Sawczuk and Bogumiła Skotarczak for providing genomic DNA of B. divergens from Ix. ricinus tick collected in Poland.

Financial support for this study was provided in part by grants-in-aid from the Ministry of Education, Science and Culture of Japan and by the Ministry of Health, Labor and Welfare of Japan (H25-Shinko-Ippan-008 and H25-Shinko-Shitei-009). Support was also provided by a Grant-in-Aid for Cooperative Research from Rakuno-Gakuen University and by Gakujutsu Frontier Cooperative Research in Rakuno-Gakuen University.

Transcontinental Movement of Asian Genotype Chikungunya Virus

To the Editor: Chikungunya virus (CHIKV), a mosquito–transmitted virus (family Togaviridae, genus Alphavirus), was first isolated >60 years ago in Africa and is responsible for epidemics of acute polyarthralgia. During CHIKV epidemics, the transmission cycle is from humans to mosquitoes, with no intervening amplifying host, and the virus can rapidly disseminate, infecting large numbers of persons. Epidemics have been described in Africa, the Middle East, Europe, India, and Southeast Asia. On the basis of detailed clinical descriptions of the disease, chikungunya fever, it appears that CHIKV caused epidemics in the Caribbean (St. Thomas, US Virgin Islands) and the southeastern coastal United States during the early 19th century (1).

Genetic studies show that the virus has evolved into 3 distinct genotypes: West African, East/Central/South African (ECSA), and Asian (2). The genotypes likely indicate independent evolution of the virus in historically isolated areas. Phenotypic differences have been described between genotypes and between individual strains, most notably an E1 mutation among some ECSA strains, which facilitates replication in Aedes albopictus mosquitoes (3). However, more recently, the movement of virus genotypes has increased dramatically, probably as a direct result of increased movement of humans and increased commercial trade. Beginning in 2005 and through 2006, the ECSA genotype virus was responsible for an explosive epidemic, during which the virus moved from coastal Kenya to islands adjacent to southeastern Africa and then to India, where >1 million cases were recorded (2). During this time, imported cases were reported worldwide, and in some instances, autochthonous transmission was detected in distal locations (4,5).

In October 2013, the arbovirus diagnostic laboratory at the Centers for Disease Control and Prevention (CDC; Fort Collins, CO, USA) detected CHIKV in human serum specimens from Yap State, Federated States of Micronesia; the specimens were collected during an epidemic of disease clinically compatible with chikungunya fever. In December 2013, the French National Reference Centre for arboviruses confirmed that CHIKV was responsible for an epidemic occurring on St. Martin Island, French West Indies, in the Caribbean (6). In January 2014, the Caribbean Public Health Agency detected CHIKV in 2 human serum specimens from the British Virgin Islands (BVI); the samples were subsequently confirmed by CDC to be positive for CHIKV.

By using next-generation sequencing, we determined the complete nucleotide sequence for 1 of the CHIKV specimens detected in BVI and for 2 of the CHIKV specimens detected in Yap. DNA libraries for next-generation sequencing were prepared directly from RNA extracted from serum, and the amplified libraries were sequenced by using the Ion Torrent Personal Genome Machine (Life Technologies, Grand Island, NY, USA). The CLC Genomics Workbench (CLC bio, Aarhus, Denmark) and Lasergene NextGen (DNASTAR, Madison, WI, USA) were used to analyze and assemble raw sequence reads. ClustalW (http://www.ebi.ac.uk/Tools/msa/clustalw2/) was used to align the complete genome sequences with a variety of CHIKV sequences, representing the 3 genotypes, from GenBank. Nearly identical phylogenetic trees were generated by several methods (i.e., minimum evolution, maximum likelihood, neighbor-joining); a representative neighbor-joining tree generated and analyzed with 1,000 replicates for bootstrap testing is shown in the Figure.
Sika Deer Carrying *Babesia* Parasites Closely Related to *B. divergens*, Japan

Technical Appendix

![Map of Japan showing prefectures where rDNA genes of *Babesia divergens*-like parasites were detected by PCR in blood samples from sika deer (black areas). Sample identification numbers are listed under prefecture names; numbers in parentheses indicate the number of positive samples/total number tested samples. A list of prefectures where no positive samples were found is shown at the bottom of the figure; the number of animals tested is shown in parentheses.](image-url)

Prefectures with no sika deer positive for *Babesia* spp. (N): Chiba (5), Shizuoka (3), Hyogo (1), Hiroshima (5), Tokushima (5), Oita (3), Kumamoto (4), Kagoshima (4)
