We study continuous time random walks (CTRW) with power law distribution of waiting times under resetting which brings the walker back to the origin, with a power-law distribution of times between the resetting events. Two situations are considered. Under complete resetting, the CTRW after the resetting event starts anew, with a new waiting time, independent of the prehistory. Under incomplete resetting, the resetting of the coordinate does not influence the waiting time until the next jump. We focus on the behavior of the mean squared displacement (MSD) of the walker from its initial position, on the conditions under which the probability density functions of the walker’s displacement show universal behavior, and on this universal behavior itself. We show, that the behavior of the MSD is the same as in the scaled Brownian motion (SBM), being the mean field model of the CTRW. The intermediate asymptotics of the probability density functions (PDF) for CTRW under complete resetting (provided they exist) are also the same as in the corresponding case for SBM. For incomplete resetting, however, the behavior of the PDF for CTRW and SBM is vastly different.

I. INTRODUCTION

Recently, there is a splash of interest in statistical properties of different stochastic processes under resetting, when a random process is interrupted by a resetting event, and restarts anew from prescribed initial conditions. The interest to this kind of processes is nurtured by their abundance in nature and by their importance in search, see \[1\] for the review. The situation is mostly exemplified by a time-dependent position of a particle which performs some kind of random motion and returns to the origin on the resetting event. The random motion under stochastic resetting can thus be considered as the interplay of two distinct random processes: the resetting process, a point process on the real line representing the time axis, and particle’s motion between the resetting events, the displacement process.

The waiting time distribution function between two resetting events can be exponential \[2\], deterministic (the most effective one for the search processes) \[3\], power-law \[4\] or of other type \[3, 5–7\]. Most studies treat the resetting as an instantaneous event \[1\], but also the situations when some time is needed by the particle to come back to the initial position were considered \[8, 11\]. The first study of resetting has been devoted to Brownian motion \[2\] as a displacement process, later the discussion has been generalized for other types of motion, such as Lévy flights \[12, 13\]. Lévy walks \[14\], scaled Brownian motion (SBM) \[15, 16\], and continuous time random walks (CTRW) \[17–21\]. This last situation is the topic of the present work.

Continuous time random walk (CTRW) is a process, when the time of the next step of a random walk is chosen according to a certain probability distribution \[22\]. The applications of CTRW range from charge carrier motion in disordered semiconductors \[24\] to earthquake modeling \[23, 26\], biology \[27\], and economics \[28, 29\]. The properties of CTRW with an exponential waiting time density \(\psi(t) = re^{-rt}\) correspond to normal diffusion \[22\], with the mean squared displacement (MSD) \(\langle x^2(t)\rangle\) growing linearly in time, but the properties of CTRW with a power-law waiting time probability density function (PDF) \(\psi(t) \sim t^{-1-\alpha}\) (with \(0 < \alpha < 1\)) are quite different, giving rise to a slower, subdiffusive behavior with \(\langle x^2(t)\rangle \propto t^\alpha\). The properties of such subdiffusive CTRW under Poissonian resetting were recently considered in Ref. \[21\], providing a nice introduction to the problem of resetting in CTRW.

On the mean field level some properties of CTRW (for example, its aging) resemble those of subdiffusive scaled Brownian motion (SBM), a diffusion process with the time-dependent diffusion coefficient \(D(t) \sim t^{\alpha-1}\) and the mean-squared displacement (MSD) \(\langle x^2(t)\rangle \sim t^\alpha\) \[30\]. The SBM is a Markovian process, while CTRW is a non-Markovian (semi-Markovian) one. Both random processes, the CTRW and the SBM are processes with non-stationary increments. However, in SBM this non-stationarity is modeled via the explicit time dependence of the diffusion coefficient, while the CTRW, being of the renewal class, lacks explicit time dependence of its parameters. Therefore, some properties of the processes (for example, their behavior under confinement) differ \[31\].

The non-stationarity of increments of the displacement process leads to two different situations under resetting, which were indistinguishable if the increments of the displacement process were stationary. The first one corresponds to the case when the memory on the course of the displacement process preceding the resetting event is fully erased, and the second one to the case when this memory is partially retained: The dynamics of the underlying process can be either rejuvenated after resetting or not influenced by the resetting of the coordinate. We will refer to the first case as to the one of complete resetting, while the second case will be referred to as the case of incomplete resetting. In SBM these two situations correspond to the cases when the time dependent diffusion coefficient \(D(t)\) also resets to the initial value.
asymptotic form of the CTRW’s PDFs. Therefore, the use the real space / time domain approach, relying on the power-law distribution, are awkward to analyze. There- these, for the case when the resetting times follow a Montoll wait-first scheme, although the jump-first vari-

ation time defining the random number of steps (operational time) directing process (subordinator, play (subordination) of two distinct random processes: 

A standard (“wait-first”) CTRW starts at \( x = 0 \) at time \( t_0 \) (in a situation without resetting this is typically put to zero) with the waiting time \( \tau_0 \). Other variants of the CTRW include the walks starting from a jump (similar to the corresponding correlated model of \[38\]), the walks anticipating the next jump after the observation time \( t \) (“oracle” walk) and other clustered models, \[39\]. The CTRW by itself may be considered as an inter-

play (subordination) of two distinct random processes: The parent process, being a simple random walk with discrete steps, and the directing process (subordinator, operational time) defining the random number of steps the parent process made up to the physical time \( t \). In this work we will consider resetting of the classical Sher-

Montoll wait-first scheme, although the jump-first variant will appear at intermediate steps of our discussion. Although general expressions may be obtained in a Fourier-Laplace domain, like it was done in Ref. \[21\], these, for the case when the resetting times follow a power-law distribution, are awkward to analyze. There-

fore, for getting asymptotic expressions for PDFs we will use the real space / time domain approach, relying on the asymptotic form of the CTRW’s PDFs. Therefore, the methods applied in the present work differ considerably from those used previously.

B. Event diagrams, notation, and general considerations

As we already mentioned, two situations are consid-

ered. In the first one, after a resetting the CTRW process starts anew, from a new waiting time which is independ-

ent of the prehistory of the process (complete resetting). This case corresponds to the first model of Ref. \[21\] and will be denoted as case (1) in the text and in figures. The case of incomplete resetting (case (2)) corresponds to the second model of Ref. \[21\]. In this case the coordinate of the walker is set to zero under resetting, which however does not interrupt the waiting period. In this case the memory on the beginning of the waiting period of the CTRW is not erased.

The event diagrams, showing the temporal order of jumps of CTRW and resetting events for the two mod-

els are displayed in Fig. \[1\] and elucidate the notation used. Thus, in the case (1) a wait-first (standard) CTRW starts anew at time of the resetting event \( t_r \), which is the backward recurrence time of the resetting process. The total duration of the observed part of the CTRW (which is the time interval between the last resetting event at \( t_r \) and the time \( t \) at which the position of the walker is measured) is equal to \( \Delta t = t - t_r \). For the case (2) of incomplete resetting, the resetting time falls into a waiting time between the two steps of the CTRW (or in the very first waiting time between the preparation and the first step), which is not interrupted by the resetting event. Since the backward recurrence time \( t_r \) of the resetting process now corresponds to the aging time of the CTRW, the waiting time for the first step in CTRW after resetting (the forward recurrence time for the directing process \( t_f \)) will typically be longer than in the previous case due to aging effects \[22\]. In this case we consider a jump-first CTRW starting at this forward recurrence time of a CTRW following the backward recurrence time for resetting. The total duration of the observed part of this jump-first CTRW is then \( \Delta t' = t - t_r - t_f \).

Notation: the waiting time PDF of the resetting process will be denoted by \( \phi(t) \), its time-dependent rate is \( \kappa(t) \) and its survival probability is \( \Phi(t) \). The waiting time PDF of the directing process is \( \psi(t) \), its time-dependent rate is \( \mu(t) \) and its survival probability is \( \Psi(t) \). The exact forms used in calculations are:

\[
\phi(t) = \frac{\beta \alpha^\beta}{(\tau_0 + t)^{1+\beta}}; \quad \Phi(t) = \frac{\tau_0^\beta}{(\tau_0 + t)^{\beta}}, \quad (1)
\]

and

\[
\psi(t) = \frac{\alpha \tau_0^\alpha}{(t_0 + t)^{1+\alpha}}; \quad \Psi(t) = \frac{\tau_0^\alpha}{(t_0 + t)^{\alpha}}. \quad (2)
\]

For \( \beta < 1 \) the asymptotics of the Laplace transform of \( \Phi(t) \) is \( \Phi(s) \approx \Gamma(1 - \beta)s^{\beta-1}\tau_0^\beta \), and \( \phi(s) \approx 1 - \Gamma(1 - \beta)s^{\beta} \tau_0^\beta \).
FIG. 1. The event diagrams of CTRW under complete (1) and under incomplete (2) resetting. The renewal events of the CTRW are denoted by black and gray filled squares, the renewals of the resetting process are denoted by empty circles. The difference between the two situations is that the time of the last renewal of the resetting process before the observation (backward recurrence time for resetting) is the time of the (new) beginning of the wait-first CTRW in (1), and the aging time of the CTRW in (2). The new beginning of the CTRW in (1) is denoted by a larger empty square (there is no jump taken at this time), and the time $\Delta t = t - t_0$ corresponds to the observed duration of the wait-first CTRW. In (2) the backward recurrence time for the resetting process is the aging time for the CTRW, and the first jump of the CTRW takes place at time $t_1$, denoted by a larger black square. This time corresponds to the forward recurrence time of the CTRW after aging. The observed duration of the jump-first CTRW $\Delta t'$ corresponds to $t - t_1$.

The stepping rate of the CTRW for $\alpha < 1$ is given by

$$
\mu(s) = \frac{1}{1 - \psi(s)} \approx \frac{1}{\Gamma(1 - \alpha)} (s \tau_0)^{-\alpha},
$$

(3)

in the Laplace domain and in the time domain, respectively.

The stepping rate of the CTRW for $\beta < 1$ are given by

$$
\kappa(s) = \frac{1}{1 - \phi(s)} \approx \frac{1}{\Gamma(1 - \beta)} (s \tau_0)^{-\beta}.
$$

(3)

in the Laplace domain and in the time domain, respectively.

The mean number of steps performed up to time $t$ is then the integral of the stepping rate. For $\alpha < 1$ it is given by

$$
\langle n(t) \rangle = \int_0^t \mu(t') dt' = \frac{\sin \pi \alpha}{\pi \alpha} \left( \frac{t}{t_0} \right)^\alpha.
$$

(3)

The MSD in a CTRW is given by

$$
\langle x^2(t) \rangle = a^2 \langle n(t) \rangle
$$

(6)

where $a^2$ is the mean squared displacement in a single step, so that in our case

$$
\langle x^2(t) \rangle = a^2 \frac{\sin \pi \alpha}{\pi \alpha t_0^\beta} t^\alpha.
$$

(7)

The coefficient of anomalous diffusion $K_\alpha$ is normally defined via

$$
\langle x^2(t) \rangle = 2 K_\alpha t^\alpha,
$$

(8)

so that in our case

$$
K_\alpha = \frac{1}{2} \frac{\sin \pi \alpha}{\pi \alpha} \frac{a^2}{t_0^\beta}.
$$

(9)

For $\alpha > 1$ (the case which would correspond to normal diffusion for CTRW without resetting) we have

$$
\mu(t) \simeq \frac{\alpha - 1}{t_0}.
$$

(10)

and

$$
\langle n(t) \rangle \simeq (\alpha - 1) \frac{t}{t_0}.
$$

(11)

(both expressions hold for $t \gg t_0$). The (normal) diffusion coefficient reads

$$
K = K_1 = \frac{\alpha - 1}{2} \frac{a^2}{t_0^\beta}.
$$

(12)

The mean waiting time for the resetting event in the case $\beta > 1$ is $\tau_0/(\beta - 1)$, and the resetting rate is the inverse of this:

$$
K(t) \simeq \frac{\beta - 1}{\tau_0}.
$$

(13)

The PDF $p_r(t_r|t)$ of the last resetting before the observation at time $t$ is given by

$$
p_r(t_r|t) = K(t_r) \Phi(t - t_r).
$$

(14)

The meaning of this equation is that the $K(t_r) dt_r$ defines the probability to have a resetting event between $t_r$ and $t_r + dt_r$, and $\Phi(t - t_r)$ the probability that no resetting event took place afterwards. The distribution of the duration of the part of CTRW observed after the resetting $\Delta t = t - t_r$ follows by the change of variables:

$$
p(\Delta t|t) = K(t - \Delta t) \Phi(\Delta t).
$$

(15)

The explicit expressions for this probability density differ for $\beta < 1$ and $\beta > 1$. Thus, for $t \gg \tau_0$ we have:

$$
p(\Delta t|t) = \frac{\sin \pi \beta}{\pi} \left( \frac{t - \Delta t}{\tau_0 + \Delta t} \right)^{\beta - 1} (\tau_0 + \Delta t)^{-\beta} \quad \text{for} \quad \beta < 1
$$

(16)
and
\[
p(\Delta t | t) = \frac{\beta - 1}{\tau_0^{1-\beta}} \frac{1}{(\tau_0 + \Delta t)^\beta} \quad \text{for } \beta > 1. \tag{17}\]

According to our discussion accompanying Fig.1, the PDFs of the CTRW under resetting \(P(x,t)\) is given by mixtures of the PDFs (Green’s functions) of the CTRW \(G_{1,2}(x, \Delta t)\) of the wait first or jump first CTRW in cases (1) and (2), respectively. These Green’s functions are weighted with the probability density \(p(\Delta t | t)\) of the observed duration of the corresponding walk \(\Delta t\), conditioned on the observation time \(t\) in the case (1) or with the probability density of the time \(\Delta t'\) elapsed between the first step of the walk after the resetting and the end of the observation, \(p_2(\Delta t' | t)\) (vide infra). Thus,
\[
P_1(x,t) = \int_0^t G_1(x, \Delta t)p(\Delta t | t)d\Delta t \tag{18}\]
and
\[
P_2(x,t) = \int_0^t G_2(x, \Delta t')p_2(\Delta t' | t)d\Delta t'. \tag{19}\]
The MSD \(R^2(t) = \langle x^2(t) \rangle = \int_0^\infty x^2 \mathcal{P}(x,t)dx\) may be obtained by integration of Eqs. (13) or (19) but can be obtained much easier using Eq. (18), as outlined in Sec. III. We will follow the second way since it allows us for obtaining additional information about the typical (mean) number of steps of the CTRW made during the \(\Delta t\) period, which will be useful in what follows. This information is necessary because the calculations of Sec. IV are performed under assumption that this number of steps is large: only under this condition the universal intermediate asymptotics can appear.

III. MEAN NUMBERS OF STEPS AND MEAN SQUARED DISPLACEMENTS

The calculation of the MSD is essentially very simple because for a non-biased CTRW the mean squared displacement, both for aged, and for non-aged situation is proportional to the mean number of steps made during the observation time \(\tau_0\),
\[
\langle x^2(t) \rangle = a^2 \langle n_{1,2}(\Delta t) \rangle, \tag{20}\]
where \(a^2\) is the mean squared length of the step, and the double mean is taken over the realizations of the direct process of the CTRW (i.e. over the CTRW waiting times), and over the duration \(\Delta t\) of the period between the last resetting and the observation time. For given \(t_r\) (or \(\Delta t\)), the mean numbers of steps \(n_1(\Delta t)\) for the complete resetting (the average over all possible realization of the waiting times of the direct process of the CTRW) is given by
\[
\langle n_1(\Delta t) \rangle = \langle n(\Delta t) \rangle \tag{21}\]
with \(\langle n(\Delta t) \rangle\) given by Eq. (I). For the incomplete resetting we have for the same average
\[
\langle n_2(\Delta t) \rangle = \langle n(t) \rangle − \langle n(t_r) \rangle. \tag{22}\]
The double means we are interested in are obtained by averaging these means over the distribution of \(\Delta t\) or \(t_r\).

A. The case \(0 < \beta < 1\)

For \(0 < \beta < 1\) the expressions for \(\kappa(t)\) and \(\Phi(t)\) are given by Eqs. (11) and (12). The distribution of \(\Delta t\) at given \(t\) is thus given by
\[
p_1(\Delta t | t) = \frac{\sin \pi \beta}{\pi} \frac{\tau_0^{1-\beta} (t - \Delta t)^{\beta-1}}{(\tau_0 + \Delta t)^\beta}, \tag{23}\]
which for longer \(\Delta t\) gets independent from \(\tau_0\). Thus,
\[
p_1(\Delta t | t) \simeq \frac{\sin \pi \beta}{\pi} (t - \Delta t)^{\beta-1} \Delta t^{-\beta}. \tag{24}\]
For the case (2) the distribution of the aging time is given by the similar expression and the distribution of \(t_r\) for given \(t\) is
\[
p_2(t_r | t) \simeq \frac{\sin \pi \beta}{\pi} (t_r)^{\beta-1} (t - t_r)^{-\beta}. \tag{25}\]
Now we turn to calculating the corresponding means.

a. The case \(\alpha \geq 1\) (normal diffusion). For both complete and incomplete resetting we get
\[
\langle \langle n_{1,2}(\Delta t) \rangle \rangle = \frac{\alpha - 1}{t_0} \int_0^t \Delta t p_1(\Delta t | t)d\Delta t \tag{26}\]
\[
= \frac{\alpha - 1}{t_0} \sin \frac{\pi \beta}{\pi} \int_0^t (1 - \xi)^{1-\beta}d\xi \tag{27}\]
Changing the variable of integration to \(\xi = \Delta t/t\) we get
\[
\langle \langle n_{1,2}(\Delta t) \rangle \rangle = \frac{\alpha - 1}{t_0} \sin \frac{\pi \beta}{\pi} \int_0^1 (1 - \xi)^{1-\beta}d\xi \tag{28}\]
and get the final result applicable for \(0 < \beta < 1\) and \(\alpha \geq 1\):
\[
\langle \langle n_{1,2}(\Delta t) \rangle \rangle = \beta \frac{t}{\tau}. \tag{29}\]
b. The subdiffusive case $0 < \alpha < 1$. Now, for case (1) of complete resetting we have

$$
\langle n_1(\Delta t) \rangle = \int_0^t \sin \frac{\pi \alpha}{\pi} \left( \frac{t}{t_0} \right)^\alpha p_1(\Delta t|t) d\Delta t \\
= \frac{\sin \frac{\pi \alpha}{\pi}}{\sin \frac{\pi \beta}{\pi}} \int_0^t \Delta t^{\alpha-\beta} (t - \Delta t)^{\beta-1} d\Delta t.
$$

Turning to the $\xi$-variable we get

$$
\langle n_1(\Delta t) \rangle = \left( \frac{t}{t_0} \right)^\alpha \frac{\sin \frac{\pi \alpha}{\pi} \sin \frac{\pi \beta}{\pi}}{\pi^2} \int_0^1 \xi^{\alpha-\beta} (1 - \xi)^{\beta-1} d\xi
\quad = \left( \frac{t}{t_0} \right)^\alpha \frac{\sin \frac{\pi \alpha}{\pi} \sin \frac{\pi \beta}{\pi}}{\pi^2} \sin \frac{\pi \alpha}{\pi} \sin \frac{\pi \beta}{\pi} B(\beta, 1 + \alpha - \beta).
$$

On the other hand, for the case (2) of incomplete resetting we get

$$
\langle n_2(t) \rangle = \left( \frac{t}{t_0} \right)^\alpha - \frac{\sin \frac{\pi \alpha}{\pi}}{\sin \frac{\pi \beta}{\pi}} t_0^\alpha \frac{\sin \frac{\pi \beta}{\pi}}{\pi} \int_0^t \left( t_r - t_r^{\alpha-1} (t - t_r)^{-\beta} \right) dt_r
\quad = \frac{\sin \frac{\pi \alpha}{\pi}}{\pi} \left[ \frac{t}{t_0} \right]^\alpha - \frac{\sin \frac{\pi \beta}{\pi}}{\pi} \int_0^1 \xi^{\alpha-\beta} (1 - \xi)^{\beta-1} d\xi.
$$

The integral in the square brackets is equal to $B(\alpha + 1, \beta - 1)$. The fact that resetting with $0 < \beta < 1$ does not change the power-law behavior in MSD is analog to the observation for SBM.

It is important to note that in both cases the mean number of steps grows with observation time, so that for these cases the intermediate asymptotics in $x$ discussed in the next section indeed appear at long times.

B. The case $\beta > 1$.

In this case the rate of resetting events is time-independent, so that

$$
p_1(\Delta t|t) = \frac{\beta - 1}{\tau_0^{-\beta}} \frac{1}{(\tau_0 + \Delta t)^\beta}
$$

and

$$
p_r(t_r|t) = \frac{\beta - 1}{\tau_0^{-\beta}} \frac{1}{(\tau_0 + t - t_r)^\beta}
$$

a. The subdiffusive case $0 < \alpha < 1$. Now, in case (1) of complete resetting

$$
\langle n_1(\Delta t) \rangle = \int_0^t \sin \frac{\pi \alpha}{\pi} \left( \frac{t}{t_0} \right)^\alpha p_1(\Delta t|t) d\Delta t
\quad = \frac{\sin \frac{\pi \alpha}{\pi}}{\sin \frac{\pi \beta}{\pi}} \int_0^t \Delta t^{\alpha-\beta} (\tau_0 + \Delta t)^{-\beta} d\Delta t.
$$

Passing to the variables $\xi = \Delta t/t$ and $z = \tau_0/t$ we get

$$
\langle n_1(\Delta t) \rangle = \frac{\sin \frac{\pi \alpha}{\pi} \sin \frac{\pi \beta}{\pi}}{\pi^2} \frac{\beta - 1}{\tau_0^{-\beta}} \int_0^1 \xi^{\alpha-\beta} (z + \xi)^{-\beta} I_1(\alpha, \beta; z).
$$

The integral $I_1(\alpha, \beta; z) = \int_0^1 \xi^\alpha (z + \xi)^{-\beta} d\xi$ will repeatedly appear in our calculations, and its asymptotic behavior in different domains of parameters is discussed in Appendix A. For $\alpha > \beta - 1$ the function $I_1(\alpha, \beta; z)$ tends to a constant (see Eq. (A17) in Appendix A) and at large $t$ we have

$$
\langle n_1(\Delta t) \rangle \sim t_0^{-\alpha} \frac{\beta - 1}{\tau_0^{-\beta}} \frac{1}{\tau_0^{-\beta}} \sin \frac{\pi \alpha}{\pi} \sin \frac{\pi \beta}{\pi} \frac{\beta - 1 + \alpha - \beta}{\pi \alpha}. \quad (37)
$$

For $\alpha < \beta - 1$ and for $t$ large the behavior is different, Eq. (A18). Now

$$
\langle n_1(\Delta t) \rangle \sim t_0^{-\alpha} \frac{\beta - 1}{\tau_0^{-\beta}} \frac{1}{\tau_0^{-\beta}} \frac{\alpha + \beta + 1}{\pi \alpha} \times B(\alpha + 1, \beta - \alpha - 1). \quad (38)
$$

Remembering that $z = \Delta t/t$ we see that the MSD stagnates:

$$
\langle n_1(\Delta t) \rangle \sim Ct_0^{-\alpha} \frac{1}{\tau_0^{-\beta}} \sin \frac{\pi \alpha}{\pi} \sin \frac{\pi \beta}{\pi} \frac{\beta - 1}{\tau_0^{-\beta}} \frac{1}{\tau_0^{-\beta}} \frac{\alpha + \beta + 1}{\pi \alpha} \times B(\alpha + 1, \beta - \alpha - 1).
$$

with

$$
C = \frac{\sin \frac{\pi \alpha}{\pi}}{\pi} (\beta - 1) B(\alpha + 1, \beta - \alpha - 1). \quad (40)
$$

The stagnant number of steps is large only if $\tau_0 \gg t_0$. Only in this case any universal behavior of the PDF can be anticipated.

On the other hand, for incomplete resetting we get

$$
\langle n(t) \rangle = \frac{\sin \frac{\pi \alpha}{\pi}}{\pi} \left( \frac{t}{t_0} \right)^\alpha - \frac{\sin \frac{\pi \alpha}{\pi}}{\pi} \int_0^t \left( \frac{t_r}{t_0} \right)^\alpha p_2(t_r|t) dt_r.
$$

In this case

$$
\langle n(t) \rangle = \frac{\sin \frac{\pi \alpha}{\pi}}{\pi} \left( \frac{t}{t_0} \right)^\alpha
\quad - \frac{\sin \frac{\pi \alpha}{\pi}}{\pi} \int_0^t \left( \frac{t_r}{t_0} \right)^\alpha \frac{\beta - 1}{\tau_0^{-\beta}} \frac{1}{(\tau_0 + t - t_r)^\beta} dt_r. \quad (42)
$$

Now we introduce the variables $z = \tau_0/t$ and $\xi = t_r/t$ as before, and write

$$
\langle n(t) \rangle = \frac{\sin \frac{\pi \alpha}{\pi}}{\pi} \left( \frac{t}{t_0} \right)^\alpha \times
\quad \left[ 1 - t^{1-\beta} \frac{\beta - 1}{\tau_0^{-\beta}} \int_0^1 \xi^{\alpha-\beta} (1 + z - \xi)^{-\beta} d\xi \right].
$$

At difference from the case $\beta < 1$, when the second term in the square brackets was smaller than unity, now it converges to unity for $t \to \infty$, and the main asymptotics of the expression comes from subleading terms. To see this it is enough to change the variable of integration to $\zeta = 1 - \xi$ and to note that the integral $\int_0^1 (1 - z)^\alpha (z + \zeta)^{-\beta} d\zeta$ diverges at lower limit for $z \to 0$. Close to this
According to Eq.(A7) we thus get for \( \beta < \tau \)
The reason is that for \( \tau \) large and can be large only in the intermediate time domain the number of steps would decay at longer times, which would hold for \( \beta > \tau \) and \( \tau \) is typically small.

The way to circumvent the calculation of the subleading terms is as follows. Introducing \( \Delta t = t - \tau \), we now may expand the expression Eq.\((22)\) in \( \Delta t \) and write
\[
\langle n(\Delta t) \rangle \approx \frac{\sin \pi \alpha}{\pi} t_0^{-\alpha} t^{\alpha-1} \Delta t.
\] (45)

Now we average this over the distribution of \( \Delta t \):
\[
\langle n(t) \rangle = \frac{\sin \pi \alpha}{\pi} t_0^{-\alpha} \frac{1 - \beta}{1 - \alpha} \int_0^t \Delta t(\tau_0 + \Delta t)^{-\beta} d\Delta t.
\] (46)

Passing to \( z = \tau_0/t \) and \( \xi = \Delta t'/t \) we get
\[
\langle n(t) \rangle = \frac{\sin \pi \alpha}{\pi} t_0^{-\alpha} \frac{1 - \beta}{1 - \alpha} t^{2 - \beta} \int_0^1 \xi(z + \xi)^{-\beta} d\xi
\]
\[
= \frac{\sin \pi \alpha}{\pi} t_0^{-\alpha} \frac{1 - \beta}{1 - \alpha} t^{2 - \beta} I_1(1, \beta, z).
\] (47)

According to Eq.\((A7)\) we thus get for \( \beta < 2 \):
\[
\langle n(t) \rangle = \frac{\sin \pi \alpha}{\pi} t_0^{-\alpha} \tau_0^{1 - \beta} \frac{1 - \beta}{2 - \beta} t^{2 - \beta}.
\] (48)

Depending on the relation between \( \alpha \) and \( \beta \) this may be a decaying or a growing function of \( t \). Thus, for \( \alpha > \beta - 1 \), \( \langle n(t) \rangle \) grows at longer times monotonically, and the typical number of steps will be large. In the opposite case the number of steps would decay at longer times, and can be large only in the intermediate time domain
\[
t \\
\ll (t_0 \tau_0^{1 - \beta})^{1/2 - \beta} = \tau_0 \left( \frac{\tau_0}{t_0} \right)^{1/2 - \beta}.
\] (49)

Noting that our asymptotic discussion is only valid for \( t_0, \tau_0 \ll t \), the necessary condition of the existence of large \( \langle n(t) \rangle \) is
\[
t_0, \tau_0 \ll \tau_0 \left( \frac{\tau_0}{t_0} \right)^{1/2 - \beta}
\] (50)

which would hold for \( t_0 \ll \tau_0 \).

For \( \beta > 2 \) for incomplete resetting we have
\[
\frac{\sin \pi \alpha}{\pi} t_0^{\alpha - 1} \frac{1 - \beta}{1 - \alpha} t^{2 - \beta} \beta B(2, \beta - 2) = C_1 t_0^{\alpha - 1} \frac{t_0}{\tau_0}.
\] (51)

which is a decaying function of \( t \). To get the intermediate domain in which \( \langle n(t) \rangle \gg 1 \) together with \( t_0, \tau_0 \ll t \) one again needs to chose \( \tau_0 \gg t_0 \).

For the case \( \alpha > 1 \) we have both for complete and for incomplete resetting
\[
\langle n(t) \rangle = \frac{\alpha - 1}{t_0} \frac{1 - \beta}{\tau_0^{\beta - 1}} \frac{t - t_r}{(\tau_0 + t - t_r)^{\beta - 1}}.
\] (52)

Changing the variable of integration to \( \xi = (t - t_r)/t \) and taking \( z = \tau_0/t \) formally leads to the same expression as before:
\[
\langle n(t) \rangle = \frac{\alpha - 1}{t_0} \frac{1 - \beta}{\tau_0^{\beta - 1}} (2 - \beta) I_1(1, \beta, z).
\] (53)

The result depends on whether \( 1 < \beta < 2 \) or \( \beta > 2 \). For \( \beta < 2 \) Eq.\((A7)\) applies with
\[
\langle n(t) \rangle = \frac{\alpha - 1}{t_0} \frac{1 - \beta}{(3 - \beta) \tau_0^{\beta - 1}} t^{2 - \beta}.
\] (54)

For \( \beta > 2 \) we have for \( z \rightarrow 0 \)
\[
\langle n(t) \rangle = \frac{\alpha - 1}{t_0} \frac{1 - \beta}{(3 - \beta) \tau_0^{\beta - 1}} t^{2 - \beta} B(2, \beta - 2)
\]
\[
= B(2, \beta - 2)(\alpha - 1)(\beta - 1) \tau_0 / t_0,
\] (55)

i.e. \( \langle n(t) \rangle \) tends to a constant which is large provided \( \tau_0 \gg t_0 \).

After \( \langle n(t) \rangle \) are found, the behavior of the MSD \( \langle x^2(t) \rangle \) follows from Eq.\((30)\). The overview of all possible regimes of the MSD is provided in Fig.\(2\).

The Table\(4\) represents the time domains in which the mean number of steps is much larger than unity. Here the notation is as follows: If \( \langle n(t) \rangle \rightarrow \infty \) in the limit \( t \rightarrow \infty \), the behavior is called asymptotic. In other cases \( \langle n(t) \rangle \gg 1 \) only when \( \tau_0 \gg t_0 \). This may take place at any value of \( t \) provided it is large enough, \( t \gg t_0, \tau_0 \) or only in some domain of \( t \) bounded from above. In the first case we will say that the behavior is independent of \( t \), and in the second case that the behavior is transient. These results will be of use in the next section.

The results for MSD as obtained in numerical simulations of the CTRWs under resetting in the corresponding domains of parameters are shown in Fig.\(4\) and corroborate our findings. For each realization of the process we generate random numbers \( s_i \) distributed according to Eq.\((2)\) for the CTRW waiting times and random numbers \( r_i \) distributed according to Eq.\((1)\) for the resetting waiting times.

We take \( t_0 = 1 \), corresponding to \( K_0 = 0.318 \) (according to Eq.\((9)\)). The values of \( \tau_0 \) differ in different simulations and are given explicitly in the captions or in the legends. The times of steps are then obtained as \( t_s = s_1 \), \( t_n = t_n - 1 + s_n \), and the procedure is stopped when \( t_n \) exceeds the maximal simulation time \( T \). The resetting times \( r_s \) are generated in a similar manner. In the simulation of the CTRW the time, starting from \( t = 0 \), is increased by an amount of \( \Delta t \), and it is checked, whether a jump, or the resetting event falls in the corresponding time interval. In the first case the walker performs the
FIG. 2. (Color online) The time dependence of the MSD in different domains of parameters $\alpha$ and $\beta$ for complete and for incomplete resetting. Note that these dependencies are the same as for the mean-field model, the scaled Brownian motion (SBM) $^{[15, 16]}$. The case of complete resetting corresponds to the renewal $^{[15]}$, and the case of incomplete resetting to the non-renewal $^{[16]}$ cases for the SBM.

![Diagram showing MSD dependence on $\alpha$ and $\beta$]

FIG. 3. Typical trajectories for CTRW with power-law waiting time density for jumps and the power-law distribution of waiting times for resetting (incomplete resetting case). The parameters are $\beta = 0.5$, $\alpha = 0.5$, $\tau_0 = 1$.

![Diagram with typical trajectories for CTRW]

jump with the length $\Delta x = 1$ either to the right or to the left with equal probability. In the second case the coordinate of the walker is set to zero. Fig. 3 displays three trajectories for the CTRW with power-law waiting time density and power-law resetting in the case of incomplete resetting. The simulations reported in other figures are performed with $10^5$ walkers.

In Fig. 4 we show the simulation results for the MSD for both complete and incomplete resetting in a broad domain of parameters. These simulations confirm that the corresponding asymptotics are the same as in the scaled Brownian motion, see Ref. $^{[15]}$ for the renewal case, corresponding to complete resetting, and Ref. $^{[16]}$ for the non-renewal case (incomplete resetting).

![Graph showing MSD evolution over time]

TABLE I. Conditions for $\langle n(t) \rangle \gg 1$.

| $\beta$ | $\alpha$ | complete resetting | incomplete resetting |
|---------|----------|--------------------|----------------------|
| $0 < \beta < 1$ | all $\alpha$ | $t \gg \tau_0, t_0$ (asymptotic) | $t \gg \tau_0, t_0$ (asymptotic) |
| $1 < \beta < 2$ | $\alpha > \beta - 1$ | $t \gg \tau_0, t_0$ (asymptotic) | $t \gg \tau_0, t_0$ (asymptotic) |
| $\alpha < \beta - 1$ | $\tau_0 \gg t_0$ (all $t$) | $\tau_0 \gg t_0$ (all $t$) |
| $2 < \beta$ | $\alpha < 1$ | $\tau_0 \gg t_0$ (all $t$) | $\tau_0 \gg t_0$ (all $t$) |
| $\alpha > 1$ | $\tau_0 \gg t_0$ (all $t$) | $\tau_0 \gg t_0$ (all $t$) |

![Table showing conditions for MSD]
a very simple form in the Laplace domain,

\[ \chi_n(s) = \psi^n(s) \frac{1 - \psi(s)}{s}, \]  

and the functions \( P_n(x) \) in Fourier domain read \( P_n(k) = \lambda^n(k) \), where \( \lambda(k) \) is the characteristic function of the displacement distribution in a single step. The PDF of the walker’s position in the Fourier-Laplace representation for this scheme is given by

\[ p_w(k, s) = \frac{1}{1 - \lambda(k)\psi(s)} \frac{1 - \psi(s)}{s}. \]  

Another scheme, the “jump first” one, differs only in the fact that the walk starts not from a waiting time but from a jump at \( t = 0 \), so that

\[ P_j(x, t) = \sum_{n=0}^{\infty} P_{n+1}(x)\chi_n(t), \]

and

\[ p_j(k, s) = \frac{\lambda(k)}{1 - \lambda(k)\psi(s)} \frac{1 - \psi(s)}{s}. \]

Assuming the steps to be symmetric and to have the finite second moment \( (\lambda(k) \approx 1 - \alpha^2 \lambda^2/2) \) and the waiting times to follow a power law, \( \psi(s) \approx 1 - \Gamma(1 - \alpha)t_0^\alpha s^\alpha \) we get in both cases in the lowest order in \( k \) and \( s \) (i.e. in the continuous limit of long times and large scales) the same asymptotic expression

\[ p(k, s) = \frac{s^{\alpha-1}}{k^{\frac{\alpha}{2}} \Gamma(1 - \alpha)} + s^\alpha. \]  

The combination \( \tilde{K}_\alpha = a^2/2\Gamma(1 - \alpha)t_0^\alpha \) of the specific parameters of the walk is related to the coefficient of the anomalous diffusion \( K_\alpha \) defined in Eq. (9), \( \tilde{K}_\alpha = \Gamma(\alpha)K_\alpha \). The limiting form of the Green’s function of CTRW is given by the inverse Fourier-Laplace transform of Eq. (61), and reads

\[ p_w,j(x, t) = \frac{1}{2\sqrt{K_\alpha t^\alpha}} M_{\alpha/2} \left( \frac{|x|}{\sqrt{K_\alpha t^\alpha}} \right). \]  

with

\[ M_{\alpha/2}(y) = \sum_{n=0}^{\infty} \frac{(-y)^n}{n!\Gamma[-\alpha n/2 + (1 - \alpha/2)]}. \]  

being the Mainardi function, see Appendix B. For \( |x| \) large compared to \( \sqrt{K_\alpha t^\alpha/2} \) the function \( G(x, t) \) shows a squeezed exponential tail, Eq. (158). For \( |x| \) small compared to \( \sqrt{K_\alpha t^\alpha/2} \) the function \( G(x, t) \) shows the cusp at zero which disappears only in the Gaussian case \( \alpha = 1 \). The asymptotic form, Eq. (162) applies when the number of steps performed during the time \( t \) is large.
Thus, for $|x| \ll Kt^{\alpha/2}$ the Green’s function tends to $G(0,t) = C_1 \Delta t^{-\alpha/2}$, while for $|x| \gg Kt^{\alpha/2}$ the leading asymptotics of the Green’s function is

$$G(x,t) \simeq C_2 t^{-\frac{\alpha}{2(\alpha-1)}} |x|^{\frac{2\alpha-2}{2(\alpha-1)}} \exp \left( \frac{C_3 |x|^2}{t^{\frac{\alpha}{\alpha-1}}} \right).$$

We will never need the exact form of the Green’s function but only its similarity form, Eq. (61), combined with the fact that the Mainardi function is rapidly decaying at infinity.

Now we return to our main equations, Eqs. (18) and (19). Let us assume that the PDF $P(\Delta t|t) = p_{1,2}(\Delta t|t)$ of the CTRW duration $\Delta t$ (or $\Delta t'$) follows a power law in some domain of $\Delta t$, i.e. possesses an intermediate asymptotics

$$p(\Delta t|t) = A(t) \Delta t^{-\gamma}$$

with $\gamma > 0$ in the domain $t_{\text{min}} \ll \Delta t \ll t$. Then the corresponding intermediate asymptotics of $P(x,t)$ will be

$$P(x,t) = A(t) \int_0^t d\Delta t \Delta t^{-\gamma} \frac{1}{2 \sqrt{K_0 \Delta t^{\alpha/2}}} \times$$

$$M_{\alpha/2} \left( \frac{|x|}{\sqrt{K_0 \Delta t^{\alpha/2}}} \right).$$

Introducing the scaling variable

$$\xi = \frac{|x|}{\sqrt{K_0 \Delta t^{\alpha/2}}}$$

we rewrite the last expression as

$$P(x,t) = A(t) K_0^{-\frac{\alpha}{2}} |x|^{-1-2(\gamma-1)\alpha} \times$$

$$\int_{\sqrt{K_0 \Delta t^{\alpha/2}}}^{\infty} \xi^{2(\gamma-1)\alpha} M_{\alpha/2}(\xi)d\xi.$$ (68)

The existence of the intermediate power-law asymptotics in $x$ (i.e. of the universal behavior for $|x| \ll \sqrt{K_0 \Delta t^{\alpha/2}}$) corresponds to situations when the integral stays convergent when its lower limit tends to zero, i.e. for $2(\gamma-1)/\alpha > -1$, or, in other words, for

$$\gamma > 1 - \frac{\alpha}{2}.$$ (69)

In the opposite case the integral for small $|x|$ is dominated by its behavior on the lower limit of integration, where the Mainardi function tends to a constant, so that $P(x,t) \propto \text{const.} \cdot A(t)t^{1-\gamma-\alpha/2}|x|^0$, i.e. develops a flat top. Therefore the intermediate power-law asymptotics of the PDF exists for $\gamma > 1 - \alpha/2$ and is given by

$$P(x,t) \propto A(t)|x|^{-1-2(\gamma-1)\alpha}.$$ (70)

The far asymptotics of large $|x|$ follows (up to power-law prefactors) the squeezed exponential wing of the Mainardi function.

B. Equations for the distributions of observed walk duration

The PDF of $\Delta t$ in the case of the complete resetting is given by Eq. (19) with its two special cases, Eqs. (18) and (17). The final results follow from the observations that for $\Delta t \ll t$ in the case (1) for $\beta < 1$

$$p_1(\Delta t|t) = \frac{\sin \pi \beta}{\pi} (t - \Delta t)^{2\beta-1} \Delta t^{-\beta} \simeq \frac{\sin \pi \beta}{\pi} t^\beta - \Delta t^{-\beta}$$

so that $A(t) \sim t^{\beta-1}$ and $\gamma = \beta$, and for $\beta > 1$

$$p_1(\Delta t|t) = \frac{\beta - 1}{\tau_0(\tau_0 + \Delta t)^{-\beta}} \simeq \frac{\beta}{\tau_0} t^{-\beta}$$

so that $A(t) = \text{const.} \cdot \tau_0^{\beta-1}$ and $\gamma = \beta$.

The distribution of the duration $\Delta t'$ of the jump-first CTRW in the case (2) of incomplete resetting was not considered yet. This CTRW starts after the forward waiting time $t_f = t_1 - t_r$ after the resetting event, so that its duration is $\Delta t' = t - t_r$.

Given $t_r$ (which is the aging time of the aged CTRW), the distribution of the forward waiting time $t_f$ is given by

$$\psi_1(t_f|t_r) = \frac{\sin \pi \alpha}{\pi} \left( \frac{t_r}{t_f} \right) \alpha \frac{1}{t_r + t_f}.$$ (73)

The duration $\Delta t'$ of the following “jump first” CTRW is $\Delta t' = t - (t_r + t_f)$ if the sum $t_r + t_f$ does not exceed $t$, and is zero otherwise. Let us first fix $t_r$ and calculate the conditional PDF $p(\Delta t'|t_r,t)$:

$$p(\Delta t'|t_r,t) = \int_0^{t-t_r} dt_f \delta(\Delta t' - (t - t_r - t_f)) \left[ \psi_1(t_f|t_r) + \delta(\Delta t') \int_{t-t_r}^{t} \psi_1(t_f|t_r) dt_f \right]$$

$$= \frac{\sin \pi \alpha}{\pi} \left( \frac{t_r}{t-t_r - \Delta t'} \right) \left( \frac{t_r}{t_r + t_f} \right) \Delta t'$$

$$+ \delta(\Delta t') \int_{t-t_r}^{t} \psi_1(t_f|t_r) dt_f.$$ (74)

where $\delta(x)$ is the Dirac delta function. The weight of this $\delta$-term, the integral $I(t-t_r) = \int_{t-t_r}^{t} \psi_1(t_f|t_r) dt_f$, is the probability that no steps of CTRW were done after resetting. Now we average the expression Eq. (74) over $t_r$ which has to lay between 0 and $t - \Delta t'$ if $\Delta t'$ is nonzero:

$$p_2(\Delta t'|t) = \int_0^{t-\Delta t'} p(\Delta t'|t_r,t)p_r(t_r|t)dt_r$$

$$= \int_0^{t-\Delta t'} \frac{\sin \pi \alpha}{\pi} \left( \frac{t_r}{t - t_r - \Delta t'} \right) \left( \frac{t_r}{t_r + t_f} \right) \Delta t'$$

$$+ \delta(\Delta t') \int_0^{t} \left[ \int_{t-t_r}^{t} \psi_1(t_f|t_r) dt_f \right] p_r(t_r|t) dt_r.$$ (75)

The term with zero steps contributes to the overall normalization and corresponds to a delta-peak at the origin
in the total PDF. This term does not influence the wings of the PDF. We will denote the weight of the \( \delta \)-function in the last line by \( R \).

The explicit form of \( R \) for \( \beta < 1 \) is

\[
R = \frac{\sin \pi \alpha \sin \pi \beta}{\pi} \times \int_{0}^{\infty} t_{r}^{\beta-1}(t + t_{r})^{-\beta} \int_{t_{r}}^{\infty} t_{f}^{\alpha}(t + t_{f})^{-1} dt_{f} dt_{r}.
\] (76)

We note that the conditional PDF \( \psi_{1}(t_{f}|t_{r}) \), Eq.(23), is normalized for any \( t_{r} \), and therefore \( \int_{0}^{\infty} \psi_{1}(t_{f}|t_{r}) dt_{f} = 1 \). Note that the integrand of the second integral in Eq.(76) is non-negative, so that

\[
\int_{t_{r}}^{\infty} t_{r}^{\alpha}t_{f}^{\alpha}(t + t_{f})^{-1} dt_{f} \leq \int_{0}^{\infty} t_{r}^{\alpha}t_{f}^{\alpha}(t + t_{f})^{-1} dt_{f}
\] (77)

and therefore \( R \leq 1 \), so that the whole double integral has to be convergent (except for the limiting cases \( \alpha = 1 \) or \( \beta = 1 \) when the trigonometric prefactors vanish). On the other hand, introducing the new variables \( \xi = t_{r}/t \) and \( \eta = t_{f}/t \) we see that

\[
R = t_{0}^{\frac{\sin \pi \alpha \sin \pi \beta}{\pi}} \times \int_{0}^{\infty} \xi^{\beta-1}(1 - \xi)^{-\beta} \left[ \int_{1-\xi}^{\infty} \xi^{\alpha} \eta^{-\alpha}(\xi + \eta)^{-1} d\eta \right] d\xi.
\] (78)

The integral in this expression converges, as we have seen above, is positive, and depends only on parameters \( \alpha \) and \( \beta \), but not on \( t \). Therefore the weight of the \( \delta \)-peak tends to a constant in the course of time.

For \( \beta > 1 \) the qualitative result is the same, but the discussion is slightly different. Now

\[
p_{r}(t_{r}|t) \simeq \frac{1}{\beta - 1} \frac{\tau_{0}^{\beta-1}}{(t_{0} + t - t_{r})^{\beta}},
\] (79)

so that

\[
R = \frac{1}{\beta - 1} \frac{\sin \pi \alpha \sin \pi \beta}{\pi} \tau_{0}^{\beta-1} \times \int_{0}^{\infty} \left( \tau_{0} + t - t_{r} \right)^{-\beta} \int_{t_{r}}^{\infty} t_{f}^{\alpha}(t + t_{f})^{-1} dt_{f} dt_{r}.
\] (80)

Denoting \( \xi = \tau_{0}/t \) we write

\[
R = \frac{1}{\beta - 1} \frac{\sin \pi \alpha \sin \pi \beta}{\pi} \xi^{\beta-1} \times \int_{0}^{\infty} \left( 1 + \xi - \xi \right)^{-\beta} \int_{1-\xi}^{\infty} \xi^{\alpha} \eta^{-\alpha}(\xi + \eta)^{-1} d\eta d\xi.
\] (81)

Now we note that this expression is bounded from above (since \( R \leq 1 \)) and would tend to zero only if the double integral in the last expression converges or diverges slower that \( \xi^{1-\beta} \) for \( \xi \rightarrow 0 \). Now we introduce the new variable \( z = \eta/\xi \) in the inner integral, and write

\[
R = \frac{1}{\beta - 1} \frac{\sin \pi \alpha \sin \pi \beta}{\pi} \xi^{\beta-1} \times \int_{0}^{\infty} \left( 1 + \xi - \xi \right)^{-\beta} \int_{1-\xi}^{\infty} \xi^{\alpha} \eta^{-\alpha}(\xi + \eta)^{-1} d\eta d\xi.
\] (82)

The \( \zeta \)-dependence of the whole integral is dominated by the behavior of the integrand for \( \xi \rightarrow 1 \) when the internal integral tends to a constant

\[
\int_{0}^{\infty} z^{-\alpha}(1 + z)^{-1} dz = \frac{\pi}{\sin((1 - \alpha)\pi)}.
\] (83)

and therefore

\[
\int_{0}^{1} (1 + \xi - \xi)^{-\beta} \int_{1-\xi}^{\infty} \xi^{\alpha} \eta^{-\alpha}(\xi + \eta)^{-1} d\eta d\xi
\] \( \simeq \frac{\pi}{(\beta - 1)\sin((1 - \alpha)\pi)} \xi^{1-\beta}, \) (84)

so that for \( t \rightarrow \infty \)

\[
R \rightarrow \frac{1}{\beta - 1} \frac{\sin \pi \alpha \sin \pi \beta}{\pi} \left( \beta - 1 \right) \frac{\sin \pi \alpha}{\pi} \frac{1}{(\beta - 1)^{2} \pi} \frac{1}{\sin((1 - \alpha)\pi)}
\] \( = \frac{1}{(\beta - 1)^{2} \pi} \frac{1}{\sin((1 - \alpha)\pi)}, \) (85)

i.e. again tends to the constant. The \( \delta \)-peak only disappears for \( \beta \rightarrow \infty \) and for exponential resetting.

The main integral (the second line in Eq.(23)) is awkward, but we can still distill the general time dependence (up to prefactors). To do so we note that the intermediate asymptotics appears when for \( t_{0} \leq \Delta t' \leq t \) the function \( \hat{p}_{2}(\Delta t'|t) \) possesses a power-law asymptotics \( \hat{p}_{2} \sim A(t)\Delta t'^{-\gamma} \).

a. \( \beta < 1 \). For this case we have

\[
p(\Delta t'|t) = \int_{0}^{t-\Delta t'} p(\Delta t'|t_{r}, t)p_{2}(t_{r}|t)dt_{r}
\]

\[
= \int_{0}^{t-\Delta t'} \sin \pi \alpha \frac{1}{\pi} \left( \frac{t_{r}}{t - t_{r} - \Delta t'} \right)^{\alpha} \times \frac{1}{t - t_{r} - \Delta t'} \frac{1}{t_{r}^{\beta-1}(t - t_{r} - \Delta t')^{-\beta}} dt_{r}
\]

\[+ R\delta(\Delta t'). \] (86)

Thus:

\[
p(\Delta t'|t) = \frac{\sin \pi \alpha \sin \pi \beta}{\pi^{2}} \frac{1}{t - \Delta t'} \int_{0}^{t-\Delta t'} (t - \Delta t' - t_{r})^{\alpha} \eta^{-\alpha}(t_{r} + \eta)^{-1} d\eta
\]

\[+ R\delta(\Delta t'). \] (87)

The intermediate asymptotic power-law behavior in the wing of the PDF may appear if for \( t \) long the PDF \( p(\Delta t'|t) \) shows a power-law behavior for \( t_{0} \leq \Delta t' \leq t \), in which the \( \delta \)-peak does not play a role. To distill the power-law dependence on \( \Delta t' \) we introduce in Eq.(87).
new variables \( z = \Delta t'/t \) and \( \xi = t_r/t \) and rewrite the integral as

\[
p(\Delta t'|t) = \frac{\sin \pi \alpha \sin \pi \beta}{\pi^2} t^{-1} \frac{1}{1 - z} \times \int_0^{1-z} (1 - z - \xi)^{-\alpha}(1 - \xi)^{-\beta} d\xi. \tag{88}
\]

Now we investigate the behavior of the integral for \( z \rightarrow 0 \). This behavior depends on whether \( \alpha + \beta < 1 \) or \( \alpha + \beta > 1 \). In the first case the integral converges and tends to a constant value. This corresponds to \( \gamma = 0 \). In the second case it shows a divergence at its upper limit. Since this limit is approximately unity, we can set the second multiplier in the integrand to unity and simplify the expression:

\[
p(\Delta t'|t) \simeq C \times t^{-1} \int_0^{1-z} (1 - z - \xi)^{-\alpha}(1 - \xi)^{-\beta} d\xi. \tag{89}
\]

Now we introduce the new variable of integration \( \zeta = 1 - z - \xi \) and write:

\[
I = \int_0^{1-z} (1 - z - \xi)^{-\alpha}(1 - \xi)^{-\beta} d\xi
\]

\[
= \int_0^{1-z} \zeta^{-\alpha}(\zeta + \xi)^{-\beta} d\zeta
\]

\[
= \frac{1}{1 - \alpha} (1 - \xi)^{1-\alpha} 2F_1 \left( \beta, 1 - \alpha, 2 - \alpha; -\frac{1 - \xi}{1 - \alpha} \right),
\]

see Eq.(1.2.4.3) of Ref. [36]. Now we apply the Pfaff transformation

\[
2F_1 \left( \beta, 1 - \alpha, 2 - \alpha; x \right) = (1 - x)^{-1+\alpha} 2F_1 \left( 1 - \alpha, 2 - \alpha - \beta; 2 - \alpha; \frac{x}{x - 1} \right),
\]

so that (for \( z \rightarrow 0 \))

\[
I \rightarrow \frac{1}{1 - \alpha} z^{1-\alpha-\beta} 2F_1 (1 - \alpha, 2 - \alpha - \beta; 2 - \alpha; 1) \sim z^{1-\alpha-\beta}. \tag{92}
\]

The value of the corresponding hypergeometric function is

\[
2F_1 (1 - \alpha, 2 - \alpha - \beta; 2 - \alpha; 1) = \frac{\Gamma(2 - \alpha) \Gamma(\alpha + \beta - 1)}{\Gamma(1) \Gamma(\beta)} \tag{93}
\]

(note that \( \alpha + \beta - 1 > 0 \) is exactly the condition under which this asymptotic value is attained), so that

\[
p(\Delta t'|t) \simeq \frac{\sin \pi \alpha \sin \pi \beta \Gamma(2 - \alpha) \Gamma(\alpha + \beta - 1)}{\pi^2 \Gamma(1) \Gamma(\beta)} \times t^{-1} \left( \frac{\Delta t'}{t} \right)^{1-\alpha-\beta}, \tag{94}
\]

which corresponds to our power law with \( A(t) \propto t^{-\alpha-\beta} \) and \( \gamma = \alpha + \beta - 1 \).

b. \( \beta > 1 \). For the case \( \beta > 1 \) we have

\[
p_2(\Delta t'|t) \simeq \int_0^{t-\Delta t'} \frac{\sin \pi \alpha \pi \left( \frac{t_r}{t - t_r - \Delta t'} \right)^{\alpha}}{\pi (t - t_r - \Delta t')^{\beta - 1}} \frac{\tau_{0}^{\beta - 1}}{1 - (\tau_0 + t - t_r)^{\beta}} d\tau_r. \tag{95}
\]

Now we again introduce \( z = \Delta t'/t, \xi = \tau_0/t \) and \( z = t_r/t \) and obtain

\[
p_2(\Delta t'|t) \simeq \int_0^{1-z} \frac{\xi^{\alpha} \pi \alpha \sin \pi \beta \left( \frac{t_r}{t - t_r - \Delta t'} \right)^{\alpha}}{\pi (\beta - 1) 1 - z} \times \int_0^{1-z} \frac{\xi^{\alpha}}{(z + 1 - \xi)^{\alpha}(\zeta + 1 - \xi)^{\beta}} d\xi. \tag{96}
\]

We are interested in the asymptotic \( z \)-dependence of this expression for \( z \rightarrow 0 \). We note that at \( z = 0 \) the integral stays convergent, however the interesting condition is \( z \gg \zeta \). For both \( z \) and \( \zeta \) small the integral is dominated by the behavior of the integrand at the upper bound, where, due to the restriction \( z \gg \zeta \) we can neglect \( \zeta \) in the second multiplier in the denominator, take \( \xi^{\alpha} \approx 1 \) in the numerator and change the integration variable to \( y = 1 - \xi \):

\[
I \approx z^{-\alpha} \int_0^1 y^{-\beta} dy \approx \frac{1}{\beta - 1} z^{1-\alpha-\beta}. \tag{98}
\]

Putting this in the expression for \( p_2 \) we get

\[
p_2(\Delta t'|t) \simeq \int_0^{t-\Delta t'} \frac{\sin \pi \alpha \pi \left( \frac{t_r}{t - t_r - \Delta t'} \right)^{\alpha}}{\pi (\beta - 1) 1 - z} \times \int_0^{1-z} \frac{\xi^{\alpha}}{(z + 1 - \xi)^{\alpha}(\zeta + 1 - \xi)^{\beta}} d\xi \tag{99}
\]

and get our power law expression with \( A(t) \propto \tau_0^{\beta-1} t^\gamma \), and \( \gamma = \alpha + \beta - 1 \) like in the previous case.

The overall results for the intermediate asymptotics \( P_{1.2}(\Delta t'|t) \) are summarized in Table III.

The inspection of this table allows us to tell under which conditions we can await the power-law intermediate behavior of the PDF, when we remember that this only appears for \( \gamma > 1 - \alpha/2 \), Eq.(69). Thus, for \( \beta < 1 \) the intermediate asymptotics in the complete resetting is observed only for \( \beta > 1 - \alpha/2 \), otherwise the flat top of the PDF immediately merges with its squeezed exponential tail. For incomplete resetting with \( \alpha + \beta < 1 \) it does not exist at all (one has a delta-peak connected to the wing), and for \( \alpha + \beta > 1 \) the condition to observe the intermediate asymptotics is \( \beta > 2 - 4\alpha \) (under which condition the inequality \( \alpha + \beta > 1 \) holds automatically for all \( \alpha < 1 \)).
TABLE II. Intermediate asymptotics of random walk duration

| kind of resetting | $A(t)$ | $\gamma$ | restrictions |
|------------------|--------|----------|--------------|
| complete         | $t^{\beta-1}$ | $\beta$ | $\beta < 1$ |
|                  | $\tau_0^{-1}$ | $\beta$ | $\beta > 1$ |
| incomplete       | $t^{-1}$ | 0        | $\beta < 1, \alpha + \beta < 1$ |
|                  | $t^{\alpha-\beta}$ | $\alpha + \beta - 1$ | $\beta < 1, \alpha + \beta > 1$ |
|                  | $\tau_0^{\beta-1}t^{\alpha-1}$ | $\alpha + \beta - 1$ | $\beta > 1$ |

C. Final results

For a complete resetting the final results are as follows: The intermediate asymptotics exists for $\beta > 1 \sim \frac{\beta}{2}$, and reads

$$P(x, t) \sim \begin{cases} 
  t^{\beta-1}|x|^{-1-\frac{2(\beta-1)}{\alpha}} & \text{for } \beta < 1 \\
  |x|^{-1-\frac{2(\beta-1)}{\alpha}} & \text{for } \beta > 1.
\end{cases}$$

This behavior is exactly the same as for SBM with the corresponding exponent of the anomalous diffusion $\alpha$, see Ref. [14]. Note that for $\beta > 1$ and $\alpha < \beta - 1$ the universal form of the PDF is only transient (i.e. visible only at intermediate times) and only exists for $\tau_0 \gg t_0$.

For incomplete resetting the intermediate asymptotics is visible only for $\beta > 2 - \frac{\alpha}{2}$ and reads

$$P_2(x, t) \sim \begin{cases} 
  t^{-\alpha-\beta}|x|^{\frac{2(\alpha-\beta)-3}{\alpha}} & \text{for } \beta < 1 \\
  \tau_0^{\beta-1}t^{\alpha-1}|x|^{\frac{2(1-\beta)}{\alpha}-3} & \text{for } \beta > 1.
\end{cases}$$

We have to stress that the universal form of the Green’s functions based on taking only the lowest order contribution in $k$ is only applicable if the corresponding PDF is broad enough, i.e. typical value of $|x|$ is much larger than $a$. This implies that the number of steps of CTRW made during the time $t$ must be large. The typical number of steps is of the order of $\langle n(t) \rangle$, whose behavior was already discussed in Sec. III.

Note that for incomplete resetting the corresponding behavior represents a decaying function of $|x|$, which is “switched” between the delta-peak at the origin and the squeezed exponential tail, starting late. This behavior differs from the one observed in SBM both with respect to the existence of the $\delta$-peak and with respect to the presence of the $\alpha$-dependence in the corresponding power law. Both features are connected with the fact that the first step of the CTRW after resetting follows very late after the resetting event. This is a true fluctuation effect, which is not captured by the mean-field SBM-description. Note that since the prefactor of $|x|$ explicitly depends on time the situation is always nonstationary. In this case again the universal asymptotic behavior in the case $\alpha < \beta - 1$ is only observable for $t_0 \ll \tau_0$.

The overview about intermediate power-law asymptotics of the PDFs is given in Fig. 6. The examples of such asymptotics as seen in numerical simulations, are given in Figs. 5 and 7.

FIG. 5. (Color online) Classification of intermediate asymptotc behaviors of $P(x, t)$ as a function of $x$ for CTRW under resetting for $0 < \alpha < 1$. The lower, white, region corresponds to the domain of parameters $\alpha, \beta$ where the intermediate power-law behavior does not occur. The intermediate triangular domain (yellow online) corresponds to the values of parameters when the power-law behavior in $|x|$ is observed at long times. The gray domains correspond to the cases when this behavior is observed only for $\tau_0 \gg t_0$ either at all times (left) or only transiently (right). The hatched domains correspond to situations when the intermediate $|x|$ asymptotics is observed for $\beta < 1$. The types of behavior are: domain 1: $p(x, t) \sim t^{\beta-1}|x|^{-1-\frac{2(\beta-1)}{\alpha}}$, domain 2: $p(x, t) \sim |x|^{-1-\frac{2(\beta-1)}{\alpha}}$, domain 3: $p(x, t) \sim t^{\alpha-\beta}|x|^{\frac{2(1-\beta)}{\alpha}-3}$, and domain 4: $p(x, t) \sim \tau_0^{\beta-1}t^{\alpha-1}|x|^{\frac{2(1-\beta)}{\alpha}-3}$.

V. CONCLUSIONS

We have studied subdiffusive continuous time random walks (CTRWs) with power-law resetting. We have considered the incomplete resetting, when the waiting period of CTRW is unaffected by the resetting event and complete resetting, when the waiting period starts anew at the resetting event. We have shown that the behavior of MSD in CTRW under resetting is is the same as for subdiffusive SBM under the same conditions which reflects the fact that SBM can serve as a mean field approximation for the CTRW for both cases. The PDF of displacements in CTRW under complete resetting is similar to such for the renewal SBM [15]. For the CTRW with incomplete resetting the behavior of the PDF of displacements differs
Appendix A: A repeatedly appearing integral.

At several places of our calculations the integrals of the form

\[ I_1(\alpha, \beta; z) = \int_0^1 y^\alpha (z + y)^{-\beta} dy \quad (A1) \]

with \( \alpha > -1 \) and different values of parameter \( \beta \) appear, for which we are typically interested in their asymptotics when \( z \to 0 \).

This integral is essentially given by a hypergeometric function, see Eq.(1.2.4.3) of [36]:

\[ I_1(\alpha, \beta; z) = \int_0^1 y^\alpha (z + y)^{-\beta} dy = (1 + \alpha)^{-1} z^{-\beta} _2F_1(1 + \alpha, \beta; 2 + \alpha; -z^{-1}). \quad (A2) \]

To get the asymptotic behavior of this function we can apply Pfaff transformation to transform the function of the argument \( x = -z^{-1} \) which tends to infinity to a function of the argument \( \frac{x}{z^{-1}} = \frac{1}{1 - x} \) which tends to unity and use the special value of the hypergeometric function at unity given by the Gauss theorem:

\[ _2F_1(a, b; c; 1) = \frac{\Gamma(c)\Gamma(c - a - b)}{\Gamma(c - a)\Gamma(c - b)} \quad (A3) \]

which holds for

\[ \Re c > \Re(a + b). \quad (A4) \]

There are two such Pfaff transformations:

\[ _2F_1(a, b; c; x) = (1 - x)^{-b} _2F_1(b, c - a; c; \frac{x}{x - 1}) \quad (A5) \]

and

\[ _2F_1(a, b; c; x) = (1 - x)^{-a} _2F_1(a, c - b; c; \frac{x}{x - 1}), \quad (A6) \]

with the first one being useful for \( \alpha > \beta - 1 \) (when the condition Eq.(A4) for the transformed of the hypergeometric function in Eq.(A2) holds), and the second one for the opposite case \( \alpha < \beta - 1 \). Applying the first transformation we get for \( \alpha > \beta - 1 \)

\[ I_1(\alpha, \beta; z) \sim z^\alpha \frac{1}{2 + \alpha - \beta} \quad (A7) \]

i.e. tends to a positive constant.

The second transformation which applies for \( \alpha < \beta - 1 \) gives

\[ I_1(\alpha, \beta; z) \sim z^{1+\alpha-\beta} \frac{1}{1 + \alpha} \frac{\Gamma(2 + \alpha)\Gamma(\beta - \alpha - 1)}{\Gamma(1)\Gamma(\beta)} \]

\[ = z^{1+\alpha-\beta} B(\alpha + 1, \beta - \alpha - 1), \quad (A8) \]

i.e., \( I_1(\alpha, \beta; z) \) behaves as \( z^{1+\alpha-\beta} \).
Appendix B: The Mainardi function.

Let us start from our Eq. (61):  
\[ p(k, s) = \frac{s^{\alpha-1}}{k^2 K_\alpha + s^\alpha} \] (B1)

and perform the inverse transforms. We first perform the inverse Fourier-transform by noting that  
\[ \mathcal{F}^{-1} \frac{1}{k^2 + 1} = \frac{1}{2} e^{-|x|}. \] (B2)

Therefore  
\[ p(x, s) = \frac{1}{2} s^{\frac{\alpha}{2} - 1} \exp \left( -\frac{|x|}{\sqrt{K_\alpha}} s^{\frac{\alpha}{2}} \right), \] (B3)

Now we expand the exponential and perform term-wise inverse Laplace transform, noting that  
\[ \mathcal{L}^{-1} s^{-\gamma} = \frac{1}{\Gamma(-\gamma)} t^{\gamma-1} \] (B4)

(for \( \gamma \) not being a non-negative integer). Therefore we obtain  
\[ p(x, t) = \sum_{n=0}^{\infty} \left( -\frac{|x|}{\sqrt{K_\alpha}} \right)^n \frac{1}{n! \Gamma\left(-\frac{\alpha n}{2} + 1 - \frac{\alpha}{2}\right)} \exp \left( \frac{|x|}{\sqrt{K_\alpha}} t^{\frac{\alpha}{2}} \right). \]

The series in this asymptotic form represents a known special function \([33, 34]\):

\[ \sum_{n=0}^{\infty} \frac{(-y)^n}{n! \Gamma\left(-\frac{\alpha n}{2} + 1 - \frac{\alpha}{2}\right)} = \Phi_{-\alpha/2,1-\alpha/2}(y) \]

(B6)

being the Mainardi function, and \( \Phi_{a,b}(y) \) being the Write function.

The asymptotic behavior of \( p(x, t) \) for small \( |x| \) follows immediately from the series expansion of the Mainardi function. For all \( \alpha < 1 \) the function \( p(x, t) \) (as a function of \( x \)) shows the cusp at zero which disappears only in the Gaussian case \( \alpha = 1 \) when all terms of odd orders disappear due to the divergence of the Gamma-functions of whole non-positive arguments, and \( M_{1/2}(y) = \pi^{-1/2} \exp(-y^2/4) \).

The asymptotic form of the Mainardi function \([34]\) for \( y \) large is  
\[ M_{\alpha/2}(y) \simeq Ay^\alpha \exp\left(\frac{-by^\alpha}{2}\right) \] (B7)

with  
\[ A = \frac{2\pi(2-\alpha)2^{\alpha/(2-\alpha)}\alpha^{(2-2\alpha)/(2-\alpha)} - 1/2}{2(2-\alpha)} \]
\[ a = \frac{2\alpha - 2}{2(2-\alpha)} \]
\[ b = (2-\alpha)2^{\alpha/(2-\alpha)}\alpha^{\alpha/(2-\alpha)} \]
\[ c = \frac{2}{2-\alpha}. \]

Thus, for \( |x| \) large compared to \( \sqrt{K_\alpha t^{\alpha/2}} \) the leading asymptotics of function \( p(x, t) \) is  
\[ p(x, t) \simeq C_1 K_\alpha^{\frac{1}{2(2-\alpha)}} t^{-\frac{\alpha}{2\alpha-2}} |x|^{\frac{2-2\alpha}{2\alpha-2}} \exp \left( C_2 \frac{|x|^\frac{\alpha}{2(2-\alpha)}}{K_\alpha^{\frac{1}{2(2-\alpha)}}} \right) \] (B8)

with constants \( C_1 \) and \( C_2 \) deriving from the previous expressions.
