INTRODUCTION

The paediatric population has many children with developmental delay. Cerebral palsy (CP) is the commonest cause for developmental delay. Cerebral palsy is the commonest chronic disability of childhood today. It is ubiquitous, and it occurs all across the globe. It occurs from injury to the brain cells, motor defects that may be progressive and affect for their whole life. Cerebral dysfunction is also associated with movement and disorders in posture or balance. Disturbed mechanisms for balance, the abnormal tone for muscle, muscle weakness, and loss of selective motor control lead to an inability to stretch muscles and its proper functioning, and it leads to contractures and deformities in patients which affect the daily lifestyle of parents and makes patient dependable on others. Treatment should start at a very early age or at the time of diagnosis when they are infants and continued into adulthood. Without proper treatment, these children cannot become productive members of society. CP is a group of permanent disorders of movement and posture causing activity limitation, that is attributed to non-progressive disturbances in the developing brain.

It is known as “an umbrella term covering a group of non-progressive, but often changing, motor impairment syndromes secondary to lesions or anomalies of the brain arising in the early stages of its development.” When primary lesion, injury or trauma is static, the clinical pattern changes with due course of time due to growth and developmental and maturation of the central nervous system and may be called as static encephalopathy. Chief clinical feature of CP is primarily motor dysfunction, sensory, cognitive, and verbal impairment in addition to learning difficulties and behavioural problems are common.

By topographical classification of Cerebral Palsy is of 4 types that is Monoplegic CP, Hemiplegic CP, Diplegic CP and Quadriplegic CP; Uncommon form is monoplegia and triplegia. In different studies, diplegia is being the commonest form ranging from (30% - 40%) and is followed by hemiplegia which is 20% - 30%, and quadriplegia which accounts
for 10% - 15%. In a study of 1000 cases of CP from India, it was revealed that spastic quadriplegia constituted 61% of cases followed by diplegia 22%.5

Cerebral palsy is a common problem and its incidence in worldwide being 2.7 per one thousand live births.6 When Little described Cerebral palsy, and cause for it to birth trauma and this view has remained consistent for many years. A decrease in its prevalence is important to sign of success in the prevention of CP. “contrary to initial expectations with improvements in perinatal medicine including the use of fetal monitoring and cesarean section the prevalence of cerebral palsy has not decreased” was stated in a population-based study conducted in united states. Epidemiology of CP concerning weight and age- Term birth babies are comparatively less prone to cerebral palsy but most infants are term born. On the other hand, the risk of CP in preterm births is relatively high.8 There are various risk factors example low birth weight, birth asphyxia or seizure disorder, malnutrition, premature baby but several studies have assessed the relationship between chorioamnionitis and cerebral palsy in premature infants9, but most have not reported a significant association.9 But this study indicates that chorioamnionitis is a risk factor for cerebral palsy.10

The demography, causes, clinical features and management aspects are planned to study in this project to prevent complications and provide better life quality.

**METHODS**

**Type of study:** Prospective observational study

**Setting:** The present study will be conducted at the Department of Pediatrics AVBRH, JNMC Sawangi, Wardha. It will be conducted for three years, with a sample size of 113. The study will be initiated only after obtaining permission from the Institutional Ethics Committee, AVBRH, JNMC Sawangi, Wardha.

**Statistical criteria:** Population proportion=0.3

- Sample proportion=0.2
- Power=90%
- Alpha error=5%
- Sided =2
- Sample size =113

**Participants:**

**Inclusion criteria**

1) All patients with the diagnosis of cerebral palsy referred to the Department of Pediatrics either IPD or OPD.

2) Age Group for the study: children till 16 years

3) Both gender.

**Exclusion criteria**

1) Unwillingness to participate in the study.

2) Non-central causes of motor deficits

3) Age more than 16 years

The patient attending OPD will be screened for the eligibility criteria. The participants meeting the set criteria would be explained about the nature and purpose of the study. Written and informed consent will be taken from those willing to participate in the study. The would-be ensured confidentiality.

**Methodology**

After taking clearance from the ethical committee, the patient will be selected according to the inclusion and exclusion criteria. Informed written consent will be taken from every patient who agrees to follow instruction and recommendation given by the clinician. Patient biography, detail history and clinical examination will be done. The study will be conducted throughout 1 year in the department of Paediatrics Jawaharlal Nehru Medical College, Sawangi. The study population included children diagnosed with CP. Exclusion criteria were non-consenting patients with non-central causes of motor deficit. The cases were studied for presentation and sent for appropriate referrals during study and analysis was done by the use of appropriate statistical methods. The study was conducted over 1 year in the department of paediatrics JNMC, Sawangi. Ethical committee approval was obtained before the start of the study. The study population included was children diagnosed with cerebral palsy below the age of 16 years who were admitted in the pediatric department. The exclusion criteria were non-consenting patients and cases with non-central causes of motor deficit. Their history, examination and investigations were done according to the pieces of advice of the treating physician. During hospitalization, the cases were studied for presentation, causes, course, comorbidities and outcome. Children were sent for appropriate referrals during hospitalization. All the information was recorded in pre-validated proforma. The results were interpreted by the use of appropriate statistical methods.

**Variables:** Motor function, loss of developmental delay

**Bias:** Child less than 1 year of age is difficult to diagnose clinically hence it is a bias in the study as we have no lower limit of age.

**Study size:** 113 patients

**Quantitative variables:** Age, height, weight, Head circumference, BMI

**Statistical analysis:** All the obtained results will be evaluated using SPSS 6.
Expected Outcomes/Results: Results will be summarised as below- Number of cases included for analysis. Sex Distribution of study participants, sex ratio, prevalence among males and females, the age distribution of participants, topographical type of cerebral palsy, association with different clinical features, socioeconomic status as well as anthropometric measures.

DISCUSSION

As per the study CP is more common in males.11 Age distribution was for more than 5 years and less than 2 years (24%) and between 2-5 years (52%). The motor deficits in the form of difficulty in walking and the use of hands for appropriate tasks were the most common disability as the study had cases mostly with diplegic and quadriplegic CP. The most common comorbidities were pneumonia and gastroenteritis. Majority of the children were malnourished grade I (56%), grade II (30%), grade III (4%). 10% of patients have a behavioural problem. Subnormal intelligence, convulsions, malnutrition, hearing impairment, visual problems, speech and language delay, gastrointestinal problem, a dental problem, respiratory problem, orthopaedic problem, sleep disorder were commonest associated comorbidities in the cases. Several articles on different aspects of child health from this region were reviewed.12-13 A rare presentation of isolated oculomotor nerve palsy due to multiple sclerosis in a child as well as infant.14-19 Also, studies on the effects of electronic media20 and care-seeking behaviour of children’s families21 were reported. Studies from the Global Burden of Disease are also available which will help to draw the conclusion and make recommendation based on the observations.22,23

ACKNOWLEDGMENT

Authors acknowledge the immense help received from the scholars whose articles are cited and included in references to this manuscript. The authors are also grateful to authors/editors/publishers of all those articles, journals, and books from which the literature for this article has been reviewed and discussed.
