ON THE CORRELATIONS OF DIRECTIONS IN THE EUCLIDEAN PLANE

FLORIN P. BOCA AND ALEXANDRU ZAHARESCU

Abstract. Let \( R^{(\nu)}_{(x,y),Q} \) denote the repartition of the \( \nu \)-point correlation measure of the finite set of directions \( P_{(x,y)}P \), where \( P_{(x,y)} \) is the fixed point \((x, y) \in [0, 1)^2 \) and \( P \) is an integer lattice point in the square \([-Q, Q]^2 \). We show that the average of the pair correlation repartition \( R^{(2)}_{(x,y),Q} \) over \((x, y) \) in a fixed disc \( D_0 \) converges as \( Q \to \infty \). More precisely we prove, for every \( \lambda \in \mathbb{R}_+ \) and each \( 0 < \delta < \frac{1}{10} \), the estimate

\[
\frac{1}{\text{Area}(D_0)} \iint_{D_0} R^{(2)}_{(x,y),Q}(\lambda) \, dx \, dy = \frac{2\pi \lambda}{3} + O_{\text{deg}, \lambda, \delta}(Q^{-\frac{1}{10} + \delta}) \quad \text{as} \quad Q \to \infty.
\]

We also prove that for each individual point \((x, y) \in [0, 1) \), the 6-level correlation \( R^{(6)}_{(x,y),Q}(\lambda) \) diverges at any point \( \lambda \in \mathbb{R}_+^5 \) as \( Q \to \infty \), and give an explicit lower bound for the rate of divergence.

1. Introduction

In many problems one is led to consider in the Euclidean plane lines joining a fixed point \( P_0 \) (which is not necessarily an integer lattice point) with a set of integer lattice points. A natural way of measuring the distribution of directions \( P_0P, P \in \mathbb{Z}^2 \), is via correlations and consecutive spacings. When the fixed point is the origin, the problem is related to the distribution of Farey fractions with multiplicities, each fraction \( \frac{a}{q} \) in \( \mathcal{F}_Q \) being counted \( \left[ \frac{Q}{q} \right] \) times. The consecutive \( h \)-level spacing measures of customary Farey fractions were computed for \( h = 1 \) in \([4]\) and for \( h \geq 2 \) in \([1]\). Limiting correlations of Farey fractions were shown to exist and computed recently in \([5]\).

When the fixed point is not an integer lattice point, the problem of existence of limiting correlations/consecutive spacings is considerably more difficult. It is therefore natural to try to prove first some averaging results, letting the fixed point to vary in a given region. In the first part of this paper we derive such a result for the limiting pair correlation measure. The limiting average pair correlation function is constant, as in the Poisson case. What is striking however is that this constant is not 1, as in the Poisson case, but \( \frac{\pi}{3} \).

We now give a mathematical formulation of the problem. For each \( Q \geq 1 \), let \( \square_Q \) denote the set of integer lattice points in the square \([-Q, Q]^2 \), and set \( N = N_Q = \# \square_Q = (2Q+1)^2 \).

Date: April 5, 2004.
For each point $P(x,y) = (x,y)$, we consider the finite sequences $(\theta_{P(x,y)})_{P \in \square_Q}$, $Q$ large integer, of angles between the line $P(x,y)P$ and the horizontal direction. The pair correlation of this finite sequence is defined as

$$R^{(2)}_{P(x,y),Q}(\lambda) = \frac{\# \left\{ (P,P') \in \square^2_Q : P \neq P', \frac{N}{2\pi} |\theta_{P,P'}(x,y)| \leq \lambda \right\}}{N}, \quad \lambda \in \mathbb{R}_+,$$

where $\theta_{P,P'}(x,y)$ denotes the measure of the angle $\angle PP'(x,y)$.

Throughout the paper we shall consider a fixed disc $D_0$ of center $(x_0,y_0) \in [0,1)^2$ and radius $r_0$. We are interested in the asymptotic behavior of the average

$$R^{(2)}_{D_0,Q}(\lambda) = \frac{1}{\pi r_0^2} \int \int_{D_0} R^{(2)}_{(x,y),Q}(\lambda) \, dx \, dy$$

of $R^{(2)}_{(x,y),Q}(\lambda)$ over $D_0$, for fixed $\lambda > 0$ and $Q \to \infty$.

The first three sections are concerned with the proof of the following result.

**Theorem 1.1.** For every $\lambda > 0$ and $\delta > 0$

$$R^{(2)}_{D_0,Q}(\lambda) = \frac{2\pi \lambda}{3} + O_{D_0,\lambda,\delta}(Q^{-\frac{1}{10}}+\delta) \quad \text{as} \quad Q \to \infty. \quad (1.1)$$

If one replaces $D_0$ by a vertical or horizontal segment of length one, an identical asymptotic formula as in (1.1) turns out to be true. This can be proved by similar techniques as in this paper or using Erdős-Turán type discrepancy estimates, and suggests that (1.1) may be true regardless of the shape of the range of the fixed point.

The behavior of higher level correlations appears to be different. In the last section we prove that the 6-level correlations diverge for every individual fixed point. When $\nu \geq 2$, the repartition of the $\nu$-level correlation measure of the finite sequence $(\theta_{P(x,y)})_{P \in \square_Q}$ is defined for each vector $\lambda = (\lambda_1, \ldots, \lambda_{\nu-1}) \in \mathbb{R}_{+}^{\nu-1}$ by

$$R^{(\nu)}_{(x,y),Q}(\lambda) = \frac{\# \left\{ (P_1, \ldots, P_{\nu}) \in \square_Q : P_i \text{ distinct, } |\theta_{P_i,P_{i+1}(x,y)}| \leq \frac{2\pi \lambda_i}{N}, 1 \leq i \leq \nu - 1 \right\}}{N}. \quad (1.2)$$

For randomly chosen directions one would expect to obtain the Poissonian limit

$$\lim_{Q \to \infty} R^{(\nu)}_{(x,y),Q}(\lambda) = \text{Vol} \prod_{i=1}^{\nu-1} [-\lambda_i, \lambda_i] = 2^{\nu-1} \lambda_1 \ldots \lambda_{\nu-1}. \quad (1.3)$$

It turns out however that (1.3) fails in this situation. More precisely, we will show that if $\nu \geq 6$, then for every point $(x,y) \in [0,1)^2$ and for every $(\lambda_1, \ldots, \lambda_{\nu-1}) \in \mathbb{R}_{+}^{\nu-1}$, $\lim_{Q \to \infty} R^{(2)}_{(x,y),Q}(\lambda) = \infty$. This is a consequence of
Theorem 1.2. For every \((x,y) \in [0,1)^2\), every \(\lambda = (\lambda_1, \ldots, \lambda_5) \in \mathbb{R}_+^5\), and every \(\delta > 0\), for \(Q\) large enough in terms of \(x,y,\lambda\) and \(\delta\)

\[
R_{(x,y),Q}^{(6)}(\lambda) > Q^{\frac{1}{4} - \delta}.
\]

As in Theorem 1.2 one can prove

Corollary 1.3. The 6-level correlations of angles of directions \(P_{(x,y)}P\), where \(P\) is a lattice point inside an expanding region \(Q\Omega\), diverges as \(Q \to \infty\) whenever \(\Omega\) is a convex domain in \(\mathbb{R}^2\) which contains the origin.

The phenomenon is similar to the one encountered in the problem of the distribution of fractional parts of polynomials. There, one can handle the pair correlation problem generically (see [8], [3]). Moreover, in the case of the sequence \(n^2 \alpha \pmod{1}\) one is able to solve the problem for all \(m\)-level correlations for a large class of irrational numbers \(\alpha\) (see [9], [10]). However, as shown in [9], there are irrational numbers \(\alpha\) for which the 5-level correlation of fractional parts of \(n^2 \alpha\), \(1 \leq n \leq N\), diverges to infinity as \(N \to \infty\). This occurs as a result of the presence of large clusters of such fractional parts. In the case of Theorem 1.2 above, large clusters of elements of the given sequence are responsible, too, for the divergence of the 6-level correlations, and hence of any other higher level correlations.

2. A FIRST APPROXIMATION FOR \(R_Q^{(2)}(\lambda)\)

For obvious practical reasons, we try to replace from the beginning \(\theta_{P,P'}(x,y)\) by one of its trigonometric functions in the definition of \(R_Q^{(2)}(\lambda)\). Suppose that two distinct points \(P = (q,a)\), \(P' = (q',a')\) \(\in \Box_Q\), are such that \(q,q' \geq 0\) and \(\max\{a,a'\} > 0 > \min\{a,a'\}\). Then for sufficiently large \(Q\) (depending only on \(\lambda\)) we have

\[
\min_{(x,y) \in [0,1]^2} |\theta_{P,P'}(x,y)| \geq \arcsin \frac{1}{\sqrt{Q^2 + 1}} > \frac{2\pi \lambda}{N}.
\]

As a result, we may only consider in the definition of \(R_Q^{(2)}(\lambda)\) points from the same quadrant. Thus if we set

\[
\Box_Q^2 = \left\{ (P,P') \in \Box_Q^2 : P \neq P' \text{ and } P,P' \text{ belong to the same quadrant} \right\}
\]

and

\[
\beta_{Q,\lambda} = \sin \frac{2\pi \lambda}{N} = \sin \frac{2\pi \lambda}{2Q^2 + 1} = \frac{\pi \lambda}{2Q^2} + O_{\lambda}\left(\frac{1}{Q^6}\right) \quad \text{as } Q \to \infty,
\]
Then

\[
R_{(x,y),Q}^{(2)}(\lambda) = \frac{\# \left\{ (P, P') \in \Box_Q^2 : |\theta_{P,P'}(x,y)| \leq \frac{2\pi\lambda}{N} \right\}}{N}.
\]

\[(2.2)\]

For \( P = (q, a), P' = (q', a') \), \((x, y) \in \mathbb{R}^2\), we define

\[
L_{P,P'}(x,y) = (a' - y)(q - x) - (a - y)(q' - x) = \begin{vmatrix} 1 & q & a \\ 1 & q' & a' \\ 1 & x & y \end{vmatrix}.
\]

Then

\[
|\sin \theta_{P,P'}(x,y)| = \frac{2\text{Area} \Delta PP'(x,y)}{\|P(x,y)\| \cdot \|P'(x,y)\|} = \frac{|L_{P,P'}(x,y)|}{\|P(x,y)\| \cdot \|P'(x,y)\|}.
\]

For each \( P, P' \in \Box_Q \), consider the weight

\[
w_{P,P'}(Q, \lambda) = \text{Area} \left\{ (x, y) \in D_0 : |L_{P,P'}(x,y)| \leq \beta_{Q,\lambda} \|P(x,y)\| \cdot \|P'(x,y)\| \right\}.
\]

From (2.2) we infer that

\[
R_{Q}^{(2)}(\lambda) = \frac{1}{N} \sum_{(P,P') \in \Box_Q^2} w_{P,P'}(Q, \lambda).
\]

Denote

\[
\gamma = \gamma_{P,P'}(Q) = \frac{\|OP\| \cdot \|OP'\|}{Q^2} = \frac{\sqrt{q^2 + a^2} \sqrt{q'^2 + a'^2}}{Q^2},
\]

and define for every \( \mu > 0 \)

\[
A_{P,P'}(Q, \mu) = \text{Area} \left\{ (x, y) \in D_0 : |L_{P,P'}(x,y)| \leq \mu \gamma_{P,P'}(Q) \right\},
\]

\[(2.4)\]

\[
G_Q(\mu) = \frac{1}{Q^2} \sum_{(P,P') \in \Box_Q^2} A_{P,P'}(Q, \mu).
\]

In the remainder of this section we show that the asymptotic of \( R_{Q}^{(2)}(\lambda) \) as \( Q \to \infty \) is closely related to that of \( G_Q(\frac{\pi\lambda}{2}) \).

For fixed \( P, P' \), denote by \( \theta \) the angle between the line \( \ell \) determined by \( P \) and \( P' \) and the horizontal direction. Consider also the lines \( \ell_\pm \), parallel to \( \ell \) and such that \( \text{dist}(\ell, \ell_\pm) = \frac{\mu \gamma \cos \theta}{|q' - q|} \). The equation of \( \ell \) is given by

\[
(L) \quad L_{P,P'}(x,y) = 0,
\]

while the equation of \( \ell_\pm \) is given by

\[
(\ell_\pm) \quad L_{P,P'}(x,y) = \pm \mu \gamma.
\]
We see that
\[
\text{dist}(\ell_+, \ell_-) = \frac{2\mu \gamma}{|q' - q|} \cdot \cos \theta = \frac{2\mu \gamma}{\sqrt{(q' - q)^2 + (a' - a)^2}} \leq \frac{4\mu}{\sqrt{(q' - q)^2 + (a' - a)^2}}.
\]

The set whose area defines \(A_{P,P'}(Q, \mu)\) is the intersection of the strip bounded by \(\ell_+\) and \(\ell_-\) and the disc \(D_0\), thus
\[
(2.5) \quad A_{P,P'}(Q, \mu) \leq 2r_0 \text{dist}(\ell_+, \ell_-) \leq \frac{8\mu r_0}{\sqrt{(q' - q)^2 + (a' - a)^2}}.
\]
We also have
\[
(2.6) \quad A_{P,P'}(Q, \mu) \neq 0 \quad \text{only if} \quad |a'q - aq'| \leq 2\mu + |a' - a| + |q' - q|.
\]

**Lemma 2.1.** Let \(\alpha \in (0, 1]\). Let \(C\) be a compact set in \(\mathbb{R}_+\). Then for all \(\varepsilon > 0\) and all \(\mu \in C\)
\[
\frac{1}{Q^2} \sum_{P \in \square Q^\alpha, P' \in \square Q} A_{P,P'}(Q, \mu) = O_{C,D_0,\varepsilon}(Q^{\alpha-1+\varepsilon}).
\]

**Proof.** The estimate (2.5) reads as \(A_{P,P'}(Q, \mu) = O_{C,D_0,\varepsilon}(1/\|PP'\|)\). Combining it with (2.6) we see that it suffices to show that
\[
A_Q := \sum_{P \in \square Q^\alpha, P' \in \square Q} \frac{1}{\|PP'\|} \ll_{\varepsilon} Q^{\alpha+1+\varepsilon}.
\]
Taking \(P'' = (q'', a'') = (q' - q, a' - a) \in \square 2Q\), we gather
\[
A_Q \leq \sum_{\substack{P \in \square Q^\alpha, O \neq P'' \in \square 2Q \not{\subseteq} C \|OP''\|}} \frac{1}{\|OP''\|} \# \left\{ (q, a) \in [-Q^\alpha, Q^\alpha]^2 : |a''q - aq''| \ll \|OP''\| \right\}.
\]
The two conditions on \((q, a)\) above yield that \((q, a)\) should belong to the intersection of a strip of width \(\ll \|OP''\| = 1\) bounded by the lines \(y = \frac{a''}{P''} x \pm \alpha_C\) with the square \([-Q^\alpha, Q^\alpha]^2\). The number of integer lattice points inside this region is of order \(O_C(Q^\alpha)\), thus
\[
A_Q \ll C \sum_{O \neq P'' \in \square 2Q} \frac{1}{\|OP''\|} = Q^\alpha \sum_{0 < m^2 + n^2 \leq 4Q^2} \frac{1}{\sqrt{m^2 + n^2}}.
\]
Since \( r_2(k) = \{(m, n) \in \mathbb{Z}^2 : m^2 + n^2 = k\} = O_\varepsilon(k^\varepsilon) \), this gives

\[
A_Q \ll C Q^\alpha \sum_{k=1}^{4Q^2} \frac{1}{k} = Q^\alpha \sum_{k=1}^{4Q^2} \frac{r_2(k)}{\sqrt{k}}
\]

\[
\ll \varepsilon Q^\alpha \sum_{k=1}^{4Q^2} k^{-\frac{1}{2}} \ll Q^\alpha (Q^2)^{\varepsilon + \frac{1}{2}} = Q^{\alpha + 2 \varepsilon},
\]
as desired. \( \square \)

**Lemma 2.2.** For every compact set \( C \subset \mathbb{R}_+ \) and every \( \varepsilon > 0 \), there exist constants \( M_1, M_2 > 0 \) such that

\[
\frac{Q^2}{N} G_Q \left( \frac{\pi \lambda}{2} - M_1 Q^{-\frac{1}{3}} \right) - M_2 Q^{-\frac{1}{3} + \varepsilon} \leq R_2^{(x)}(\lambda) \leq \frac{Q^2}{N} G_Q \left( \frac{\pi \lambda}{2} + M_1 Q^{-\frac{1}{3}} \right) + M_2 Q^{-\frac{1}{3} + \varepsilon}.
\]

**Proof.** The trivial estimate

\[
\|P_{(x,y)}P\| = \|OP\| + O_{D_0}(1)
\]

and \( (2.1) \) yield for all \( P, P' \in \square_Q, \lambda \in C, (x, y) \in \mathbb{D}_0 \), that

\[
\beta_{Q,\lambda}\|P_{(x,y)}P\| \cdot \|P_{(x,y)}P'\| = \beta_{Q,\lambda} (\|OP\| \cdot \|OP'\| + O(Q))
\]

\[
= \left( \frac{\pi \lambda}{2Q^2} + O_{C,\lambda} \left( \frac{1}{Q^6} \right) \right) (\|OP\| \cdot \|OP'\| + O_{D_0}(Q)) = \frac{\pi \lambda \|OP\| \cdot \|OP'\|}{2Q^2} + O_{C,\lambda} \left( \frac{1}{Q} \right)
\]

\[
= \frac{\pi \lambda}{2} \gamma_{P,P'}(Q) + O_{C,\lambda} \left( \frac{1}{Q} \right) = \gamma_{P,P'}(Q) \left( \frac{\pi \lambda}{2} + O_{C,\lambda} \left( \frac{1}{Q} \right) \right)
\]

\[
= \gamma_{P,P'}(Q) \left( \frac{\pi \lambda}{2} + O_{C,\lambda} \left( \frac{1}{Q \gamma_{P,P'}(Q)} \right) \right).
\]

We first analyze the case where \( \min\{\|OP\|, \|OP'\|\} \geq Q^\frac{3}{4} \). In this case \( \gamma_{P,P'}(Q) \geq Q^{-\frac{3}{4}} \), and the relation above and the definitions of \( w_{P,P'} \) and \( A_{P,P'} \), yield \( M_1 > 0 \) such that

\[
A_{P,P'} \left( Q, \frac{\pi \lambda}{2} - M_1 Q^{-\frac{1}{3}} \right) \leq w_{P,P'}(Q, \lambda) \leq A_{P,P'} \left( Q, \frac{\pi \lambda}{2} + M_1 Q^{-\frac{1}{3}} \right).
\]

When \( \min\{\|OP\|, \|OP'\|\} \leq Q^\frac{3}{4} \), we take \( \alpha = \frac{1}{3} \) in Lemma 2.1. Since \( \beta_{Q,\lambda}\|P_{(x,y)}P\| \cdot \|P_{(x,y)}P'\| \ll C \pi \lambda \gamma_{P,P'}(Q) \) as \( Q \to \infty \), we get

\[
\sum_{\min\{\|OP\|, \|OP'\|\} \leq Q^\frac{3}{4}} w_{P,P'}(Q, \lambda) \ll C \sum_{\min\{\|OP\|, \|OP'\|\} \leq Q^\frac{3}{4}} A_{P,P'}(Q, \pi \lambda) \ll C, \varepsilon Q^{-\frac{1}{4} + \varepsilon}.
\]

\( \square \)
3. A FORMULA FOR $G_Q(\mu)$

An immediate consequence of (2.5) and (2.6) is that the contribution to $G_Q(\mu)$ of pairs of points $(P, P') \in \mathbb{Q}^2$ with $a' = a$ or with $q' = q$ is negligible. Indeed, we see from (2.6) that when $a' = a \neq 0$, the term $A_{P, P'}(Q, \mu)$ is zero unless $|q' - q| \leq 2\mu + \frac{1}{|a|} \leq 2\mu + 1$, thus the total contribution of such points to $G_Q(\mu)$ is

$$
\ll C \frac{1}{Q^2} \sum_{|q| \leq Q} \frac{8\mu r_0}{|q' - q|} \ll C \frac{1}{Q} \sum_{|q| \leq Q} \frac{1}{|q' - q|} \ll C \frac{\ln Q}{Q}.
$$

The contribution of pairs of points $(P, P') \in \mathbb{Q}^2$ with $a' = a = 0$ to $G_Q(\mu)$ is

$$
\ll C \frac{1}{Q^2} \sum_{|q|, |q'| \leq Q, q' \neq q} \frac{1}{|q' - q|} \ll \frac{\ln Q}{Q}.
$$

Similar estimates in the case $q' = q$ show that

$$(3.1) \quad G_Q(\mu) = \frac{1}{Q^2} \sum_{(P, P') \in \mathbb{Q}^2} A_{P, P'}(Q, \mu) + O_{C, D_0}\left(\frac{\ln Q}{Q}\right).$$

As a result, we shall subsequently assume that $a' \neq a$ and $q' \neq q$. We now set

$$
\alpha = \frac{a' - a}{q' - q}; \quad \beta = \frac{aq' - a'q}{q' - q}; \quad \gamma_0 = \frac{\gamma}{|q' - q|} = \frac{\sqrt{q'^2 + a'^2q'^2 + a'^2}}{Q^2|q' - q|}.
$$

The remainder of this section is elementary and is concerned with putting $G_Q(\mu)$ in a tidy form, suitable for a precise estimation which will be completed in the next section.

Let $C_0$ denote the center of $D_0$, let $\ell'$ be the line passing through $C_0$ and perpendicular to $\ell$, and denote by $A_+$ and $A_-$ the intersections of $\ell'$ with the circle $\partial D_0$, by $E_0$ the intersection of $\ell'$ and $\ell$, and by $E_{\pm}$ the intersection of $\ell'$ with $\ell_{\pm}$. Direct computation gives

$$
x_{A_{\pm}} = x_0 \mp \frac{\alpha r_0}{\sqrt{\alpha^2 + 1}} = x_0 \mp \frac{(a' - a)r_0}{\sqrt{(q' - q)^2 + (a' - a)^2}}; \quad x_{E_{\pm}} = \frac{\alpha y_0 + x_0 - \alpha \beta \mp \alpha \mu \gamma_0}{\alpha^2 + 1};
$$

$$
\|E_{\pm}E_{\pm}\| = \text{dist}(\ell_{\pm}, \ell_{\pm}) = \frac{|x_{E_{+}} - x_{E_{-}}|}{|\sin \theta|} = \frac{2\mu \gamma_0}{\sqrt{\alpha^2 + 1}} = \frac{\mu \sqrt{q'^2 + a'^2q'^2 + a'^2}}{Q^2\|PP'\|}.
$$

While ordering the points $x_{E_{+}} < x_{E_{-}}$ and $x_{A_{+}} < x_{A_{-}}$ the following situations may occur:

Case 1. $x_{E_{+}} < x_{A_{+}} < x_{A_{-}} < x_{E_{-}}$, that is

$$
\frac{\alpha y_0 + x_0 - \alpha \beta - \alpha \mu \gamma_0}{\alpha^2 + 1} < x_0 - \frac{\alpha r_0}{\sqrt{\alpha^2 + 1}} < x_0 + \frac{\alpha r_0}{\sqrt{\alpha^2 + 1}} < \frac{\alpha y_0 + x_0 - \alpha \beta + \alpha \mu \gamma_0}{\alpha^2 + 1}.
$$
Figure 1. The intersection of the strip bounded by \( \ell_+ \) and \( \ell_- \) with the disc \( D_0 \).

This gives \( \mu \gamma_0 > r_0 \sqrt{\alpha^2 + 1} \), hence

\[
r_0 \sqrt{(q' - q)^2 + (a' - a)^2} < \frac{\mu \sqrt{q^2 + a^2 \sqrt{q'^2 + a'^2}}}{Q^2} \leq 2\mu.
\]

Suppose first that \( |a' - a| \leq |q' - q| \). By \( p \) we know that for fixed \( (q, q') \), the expression \( D = aq' - a'q \) will only take values between \(-2\mu - \frac{4\mu}{r_0^2}\) and \( 2\mu + \frac{4\mu}{r_0^2} \). Hence the number of solutions \((a, a')\) of \( aq' - a'q = D \) is of order \( O_C(d) \), where \( d \) is the greatest common divisor of \( q \) and \( q' \). But \( d \leq \frac{2\mu}{r_0^2} \), hence this is actually \( O_C(1) \) and the contribution to \( G_Q \) is

\[
\ll \frac{1}{Q^2} \sum_{|q|, |q'| \leq Q} \sum_{|a|, |a'| \leq Q} 1 \ll \frac{1}{Q^2} \sum_{|q|, |q'| \leq Q} \sum_{0 < |a' - a| \leq |q' - q|} 1 \ll \frac{1}{Q}.
\]

The case \( |q' - q| \leq |a' - a| \) is settled similarly by first summing over \((a, a')\).

**Case 2.** \( x_{A_+} < x_{E_+} < x_{A_-} < x_{E_-} \), that is

\[
|\mu \gamma_0 - r_0 \sqrt{\alpha^2 + 1}| = r_0 \sqrt{\alpha^2 + 1} - \mu \gamma_0 < y_0 - \alpha x_0 - \beta < \mu \gamma_0 + r_0 \sqrt{\alpha^2 + 1},
\]

or equivalently

\[
|a'q - aq' + (q' - q)y_0 - (a' - a)x_0 - r_0 \sqrt{(q' - q)^2 + (a' - a)^2}| < \mu \gamma.
\]
The change of variables $a' - a = a''$, $q' - q = q''$ gives

$$|a''q - aq'' - r_0 \sqrt{q'^2 + a''^2} + q''y_0 - a''x_0| < \mu \gamma \leq 4\mu.$$ 

So, keeping $a''$ and $q''$ fixed, the range of $a''q - aq''$ has cardinality $O_C(1)$. Now the equation $a''q - aq'' = K$ has either no solution $(q, a)$ when $d = \gcd(a'', q'')$ does not divide $K$, or has $O\left(\frac{d q''}{q'}\right)$ solutions $(q, a)$ when $d$ divides $K$. Thus the contribution of terms $A_{P,P'}$ with $q''^2 + a''^2 = (q' - q)^2 + (a' - a)^2 > Q$ is

$$\ll C \frac{1}{Q^2} \sum_{d=1}^{Q} \sum_{0 < |q''^2|, |a''^2| \leq \left\lfloor \frac{Q}{d} \right\rfloor_{\gcd(q''^2, a''^2) = 1}} \frac{Q}{q''^2} \cdot \frac{1}{\sqrt{Q}} \leq \frac{1}{Q^{\sqrt{Q}} d} \sum_{\substack{0 < |q''^2| \leq \lfloor \frac{Q}{d} \rfloor \leq d, d = 1}} \frac{1}{q''^2} \ll \frac{\ln^2 Q}{Q} \ll \delta Q^{-\frac{1}{2} + \delta}.$$ 

The contribution of terms $A_{P,P'}$ with $q''^2 + a''^2 = (q' - q)^2 + (a' - a)^2 \leq Q$ is

$$\ll C \frac{1}{Q^2} \sum_{1 \leq d \leq \sqrt{Q}} \sum_{0 < |q''^2|, |a''^2| \leq \lfloor \frac{Q}{d} \rfloor} \frac{Q}{q''^2} \cdot \frac{1}{d q''^2} \leq \frac{1}{Q^{\sqrt{Q}} d} \sum_{\substack{0 < |q''^2| \leq \lfloor \frac{Q}{d} \rfloor \leq d, d = 1}} \frac{1}{d q''^2} \ll Q^{-\frac{1}{2}}.$$ 

**Case 3.** $x_{E+} < x_{A+} < x_{E-} < x_{A-}$, that is

$$-\mu \gamma_0 - r_0 \sqrt{\alpha^2 + 1} < y_0 - \alpha x_0 - \beta < -|\mu \gamma_0 - r_0 \sqrt{\alpha^2 + 1}|.$$ 

We infer as in Case 2 that the contribution of $A_{P,P'}$ is in this case too $O_{\delta}(Q^{-\frac{1}{2} + \delta})$.

**Case 4.** $x_{A+} < x_{E+} < x_{E-} < x_{A-}$, that is

$$\mu \gamma_0 - r_0 \sqrt{\alpha^2 + 1} < y_0 - \alpha x_0 - \beta < -\mu \gamma_0 + r_0 \sqrt{\alpha^2 + 1},$$

or equivalently

$$|L_{P,P'}(x_0, y_0)| < r_0 \sqrt{(q' - q)^2 + (a' - a)^2} - \mu \gamma = r_0 \|PP'\| - \mu \gamma.$$ 

Denote $k = q' - q$ and $\ell = a' - a$. The interval $I_{k, \ell} = [r_0 \sqrt{k^2 + \ell^2} - ky_0 + \ell x_0 - \mu \gamma, r_0 \sqrt{k^2 + \ell^2} + ky_0 + \ell x_0]$ has length $\mu \gamma \ll C 1$. Hence we find that the contribution of terms $A_{P,P'}$ for which $r_0 \|PP'\| - \mu \gamma < L_{P,P'}(x_0, y_0) < r_0 \|PP'\|$ to $G_Q$ is

$$\ll C \frac{1}{Q^2} \sum_{|k|, |\ell| \leq Q} \sum_{|q'|, |a'| \leq Q} \frac{1}{\sqrt{k^2 + \ell^2}} \ll \frac{1}{Q^2} \sum_{k, \ell = 1}^{Q} \frac{Q \gcd(k, \ell)}{\sqrt{k^2 + \ell^2}} \cdot \frac{1}{\sqrt{k^2 + \ell^2}} \leq \frac{1}{Q^2} \sum_{d=1}^{Q} \frac{1}{d} \sum_{k_0, \ell_0} \frac{[Q]}{k_0 \sqrt{k_0^2 + \ell_0^2}} \ll \frac{1}{Q} \sum_{d=1}^{Q} \frac{1}{d} \sum_{k_0=1}^{Q} \frac{1}{k_0 \sum_{\ell_0=1}^{Q} \frac{1}{\ell_0}} \ll \frac{\ln^3 Q}{Q}.$$
One shows similarly that the contribution of points $P, P'$ for which $-r_0\|PP'\| + \mu \gamma < L_{P',P'}(x_0, y_0) < r_0\|PP'\|$ is of the same order. Therefore by (3.1) and the previous considerations we infer that

\[
G_Q(\mu) = \frac{1}{Q^2} \sum_{(P, P') \in \tilde{\square}_Q} A_{P, P'}(Q, \mu) + O_{C, \beta_0, \delta}(Q^{-\frac{3}{2} + \delta}).
\]

\[
\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{figure2.png}
\caption{Figure 2.}
\end{figure}
\]

Next $S_{P, P'}$ is approximated by elementary calculus.

\textbf{Lemma 3.1.} The area of the region inside the circle of radius $r_0$ centered at the origin and inside the strip bounded by the vertical lines $y = t_1$ and $y = t_2$, $-r_0 < t_1 \leq t_2 < r_0$, is given, for small $t_2 - t_1$, by

\[
A_{r_0}(t_1, t_2) = 2(t_2 - t_1) \sqrt{r_0^2 - \left(\frac{t_1 + t_2}{2}\right)^2} + O_{r_0}(\varepsilon(t_2 - t_1)^{\frac{3}{2}})
\]

\textbf{Proof.} The error is seen to be given (see Figure 2) by

\[
\int_{t_1}^{t_1 + t_2} \left(\sqrt{r_0^2 - \left(\frac{t_1 + t_2}{2}\right)^2} - \sqrt{r_0^2 - t^2}\right) dt + \int_{t_2}^{t_1 + t_2} \left(\sqrt{r_0^2 - t^2} - \sqrt{r_0^2 - \left(\frac{t_1 + t_2}{2}\right)^2}\right) dt.
\]

It is $\ll (t_2 - t_1)^{3/2}$ as a result of

\[
\left|\sqrt{r_0^2 - x^2} - \sqrt{r_0^2 - y^2}\right| \leq \sqrt{|x^2 - y^2|} \leq 2\sqrt{|x - y|}.
\]

\[\square\]
We take
\[ t_{E_\pm} := \frac{x_{E_\pm} - x_{E_0}}{\sin \theta} = \frac{\sqrt{1 + \alpha^2}}{\alpha} (x_{E_\pm} - x_{E_0}) = \frac{L_{P,P'}(x_0, y_0) \mp \mu \gamma}{\|PP'\|}. \]

Notice now that
\[ (3.3) \quad t_{E_-} - t_{E_+} = \frac{2\mu \gamma}{\|PP'\|} \ll \frac{1}{\|PP'\|}, \]
denote \( k = q' - q, \ell = a' - a, \)
\[ (3.4) \quad J_{k,\ell} = [-ky_0 + \ell x_0 - r_0 \sqrt{k^2 + \ell^2}, -ky_0 + \ell x_0 + r_0 \sqrt{k^2 + \ell^2}], \]
and find that the contribution of the error provided by Lemma 3.1 in (3.2) is
\[ \frac{1}{Q^2} \sum_{(P,P') \in \mathcal{D}_Q} \frac{1}{\|PP'\|^{3/2}} = \frac{1}{Q^2} \sum_{0 < |k|, |\ell| \leq Q} \sum_{\substack{|q'|, |a'| \leq Q \text{ \text{gcd}(k, \ell) = 1} \text{ and } K_{k,\ell}}} \frac{1}{(k^2 + \ell^2)^{3/4}} \]
\[ \ll \frac{1}{Q^2} \sum_{k,\ell=1}^{Q} \frac{Q \gcd(k, \ell)}{k} \cdot \sqrt{k^2 + \ell^2} \cdot \frac{1}{(k^2 + \ell^2)^{3/4}} \]
\[ \leq \frac{1}{Q^2} \sum_{d=1}^{Q} \sum_{k_0, \ell_0=1}^{\left\lfloor \frac{Q}{d} \right\rfloor} \frac{Q d}{d k_0} \cdot \left( k_0^2 + \ell_0^2 \right)^{1/2} \cdot \frac{1}{d^{5/2} (k_0^2 + \ell_0^2)^{3/4}} \]
\[ = \frac{1}{Q} \sum_{d=1}^{Q} \frac{1}{d^{1/2}} \sum_{k_0, \ell_0=1}^{\left\lfloor \frac{Q}{d} \right\rfloor} \frac{1}{k_0 (k_0^2 + \ell_0^2)^{1/4}} \]
\[ \leq \frac{\ln Q}{Q} \sum_{d=1}^{Q} \frac{1}{d^{1/2}} \sum_{k_0}^{\left\lfloor \frac{Q}{d} \right\rfloor} \frac{1}{k_0} \sum_{\ell_0=1}^{\left\lfloor \frac{Q}{d} \right\rfloor} \frac{1}{\ell_0^{1/2}} \]
\[ \ll \ln^2 \frac{Q}{Q^{1/2}}. \]

Therefore by (3.2), Lemma 3.1, (3.3) and (3.5) we find that
\[ (3.6) \quad G_Q(\mu) = \frac{1}{Q^2} \sum_{(P,P') \in \mathcal{D}_Q} B_{P,P'}(\mu) + O_{C, d_0, \delta}(Q^{-\frac{1}{2} + \delta}), \]
\[ q' \neq q, a' \neq a, \]
\[ |L_{P,P'}(x_0, y_0)| < r_0 \|PP'\|. \]
where $B_{P,P'}(Q,\mu)$ denotes the contribution of the main term in Lemma 3.1 to (3.2), that is

$$B_{P,P'}(Q,\mu) = 2(t_E - t_E^+)^2 - \left(\frac{t_E^+ + t_E^-}{2}\right) = 2 \cdot \frac{2\mu\gamma}{\|PP'\|} \sqrt{r_0^2 - \frac{L_{P,P'}(x_0,y_0)^2}{\|PP'\|^2}}$$

(3.7)

$$= 4\mu\gamma \sqrt{r_0^2 \|PP'\|^2 - L_{P,P'}(x_0,y_0)^2} \|PP'\|^2.$$

Finally we show that, if $a' - a \leq q' - q$, one can replace $\gamma$ by $\frac{1}{Q} q'q' \left(1 + \frac{(a'-a)^2}{(q'-q)^2}\right)$ in (3.7) and (3.6). Since $|L_{P,P'}(x_0,y_0)| < r_0 \|PP'\|$, then $|q'q' - aq'| \leq (r_0 + \sqrt{x_0^2 + y_0^2}) \|PP'\|$, and

$$|q\sqrt{1 + \frac{(a'-a)^2}{(q'-q)^2}} - q'\sqrt{1 + \frac{a'^2}{q'^2}}| \leq |q'q' - aq'| \leq \left|\left|\frac{a'q' - aq'}{q'q'}\right|\right| \leq \frac{|a'q' - aq'|}{\|PP'\|} \leq Q \|PP'\| \leq Q \|PP'\| \leq Q_0 1.$$

This gives

$$\sqrt{q^2 + a^2} = q\sqrt{1 + \frac{(a'-a)^2}{(q'-q)^2}} + O_{Q_0}(1),$$

and similarly

$$\sqrt{q'^2 + a'^2} = q'\sqrt{1 + \frac{(a'-a)^2}{(q'-q)^2}} + O_{Q_0}(1).$$

Hence one can replace $B_{P,P'}(Q,\mu)$ in (3.6) by

$$W_{P,P'}(Q,\mu) = \frac{4\mu q'q' \sqrt{r_0^2 \|PP'\|^2 - L_{P,P'}(x_0,y_0)^2}}{Q^2 \max\{(q'-q)^2, (a'-a)^2\}}$$

at the cost of an error which is

$$\ll \frac{1}{Q^3} \sum_{\mu \neq k, \ell \neq k, \ell \neq \mu} \sum_{\mu \neq k, \ell \neq k, \ell \neq \mu} \frac{1}{Q\sqrt{(q'-q)^2 + (a'-a)^2}} \sum_{0<|k|,|\ell|\leq Q} \frac{\sqrt{k^2 + \ell^2}}{k} \cdot \frac{1}{Q \sqrt{k^2 + \ell^2}} \cdot \frac{\ln Q}{Q}.$$

In summary, we have shown for any $\mu$ in a fixed compact set $C \subset \mathbb{R}_+$, that

(3.8) $G_Q(\mu) = \frac{4\mu}{Q^2} \sum_{\mu \neq k, \ell \neq k, \ell \neq \mu} \sum_{\mu \neq k, \ell \neq k, \ell \neq \mu} \frac{q'q' \sqrt{r_0^2 \|PP'\|^2 - L_{P,P'}(x_0,y_0)^2}}{\max\{(q'-q)^2, (a'-a)^2\}} + O_{C,\delta}(Q^{-\frac{1}{2}+\delta})$
as \( Q \to \infty \).

## 4. Estimating the sum \( S_Q \)

By reflecting \( \mathbb{D}_0 \) about the axes and about the line \( y = x \), we see that it suffices to only estimate the contribution \( A_Q(\mu) \) to \( G_Q(\mu) \) of points \((P, P') \in (0, Q)^2\) with \( 0 < \alpha = \frac{a'-a}{q'-q} \leq 1 \). We thus consider

\[
A_Q(\mu) = 4 \mu S_Q,
\]

where

\[
S_Q = \frac{1}{Q^4} \sum_{0 < q, q' \leq Q} \sum_{0 < a, a' \leq Q} \sum_{0 < \frac{q'-q}{q'-q} \leq 1} \frac{qq' \sqrt{r_0^2 \|PP'\|^2 - L_{P,P'}(x_0, y_0)^2}}{(q'-q)^2} \cdot \frac{r_0 \|PP'\| \|L_{P,P'}(x_0, y_0)\|}{(q'-q)^2}.
\]

Then we gather from (3.8) and the above formula for \( S_Q \) that

\[
(4.1) \quad G_Q(\mu) = 8 A_Q(\mu) + O_{C,D_0,\delta}(Q^{-\frac{1}{m} + \delta}) = 32 \mu S_Q + O_{C,D_0,\delta}(Q^{-\frac{1}{m} + \delta}).
\]

Changing \( q \) to \( q' - q \) and \( a \) to \( a' - a \), we may write

\[
S_Q = \frac{2}{Q^4} \sum_{0 < a < a' \leq Q} \sum_{0 < q < q' \leq Q} \sum_{0 < \frac{q'-q}{q'-q} \leq 1} \frac{(q'-q)q' \sqrt{r_0^2(q^2 + a^2) - (y_0q - x_0a + a'q - a'q)^2}}{q^2} \cdot \frac{r_0 \sqrt{q^2 + a^2} \|y_0q - x_0a + a'q - a'q\|}{(q'-q)^2}.
\]

Putting

\[
D = aq' - a'q
\]

and taking \( J_{q,a} \) as in (3.4), that is

\[
J_{q,a} = [-qy_0 + ax_0 - r_0 \sqrt{q^2 + a^2}, -qy_0 + ax_0 + r_0 \sqrt{q^2 + a^2}],
\]

we get

\[
(4.2) \quad S_Q = \frac{2}{Q^4} \sum_{1 \leq a \leq q \leq Q} \sum_{D \in J_{q,a}} \sum_{q' \in [q, Q]} \sum_{a' \in [a, Q]} \frac{(q'-q)q' \sqrt{r_0^2(q^2 + a^2) - (y_0q - x_0a + D)^2}}{q^2}.
\]
We will prove the following result.

**Proposition 4.1.** \( S_Q = \frac{\pi r_0^2}{6} + O_{\mathcal{D}_0, \delta}(Q^{-\frac{1}{10}+\delta}) \) for all \( \delta > 0 \).

From this and (4.1) we infer the following

**Corollary 4.2.** \( G_Q(\mu) = \frac{16\pi r_0^2 \mu}{3} + O_{C, \mathcal{D}_0, \delta}(Q^{-\frac{1}{10}+\delta}) \).

Theorem 1.1 now follows combining Corollary 4.2 with Lemma 2.2.

We now start the proof of Proposition 4.1. We first lay out some notation and prove an elementary calculus lemma. Fix \( \alpha_0, \beta_0 \in \mathbb{R} \) and consider the function

\[
\Phi(t, x) = \Phi_{\alpha_0, \beta_0}(t, x) = 1 + t^2 - (\beta_0 - t\alpha_0 + x)^2,
\]

and the domain

\[
\mathcal{D} = \mathcal{D}_{\alpha_0, \beta_0} = \{(t, x) : 0 \leq t \leq 1, \Phi(t, x) \geq 0\}.
\]

Consider also the projection \( \text{pr}_2 \mathcal{D} \) of \( \mathcal{D} \) on the second coordinate, the \( x \)-section

(4.3) \( I_x = \{ t \in [0, 1] : \Phi(t, x) \geq 0 \} \),

and the \( t \)-section

(4.4) \( J_t = \{ x \in \text{pr}_2 \mathcal{D} : \Phi(t, x) \geq 0 \} \).
Define the function $\psi = \psi_{\alpha_0, \beta_0} : \text{pr}_2 \mathcal{D} \to [0, \infty)$ by

$$
\psi(x) = \int_{I_x} \sqrt{\Phi(t, x)} \, dt.
$$

**Lemma 4.3.** For every $\alpha_0, \beta_0 \in \mathbb{R}$ one has

(i) $\int_{\text{pr}_2 \mathcal{D}_{\alpha_0, \beta_0}} |\psi'(x)| \, dx \leq \sqrt{2} + \ln(1 + \sqrt{2})$.

(ii) $\int_{\text{pr}_2 \mathcal{D}_{\alpha_0, \beta_0}} \psi(x) \, dx = \iint_{\mathcal{D}_{\alpha_0, \beta_0}} \sqrt{\Phi(t, x)} \, dt \, dx = \frac{2\pi}{3}$.

**Proof.** (i) By the definition of $\Phi$ it is seen that $I_x$ is the union of one or two intervals $[a(x), b(x)]$, where $a(x)$ and $b(x)$ are equal to 0, 1, or a root of $\Phi(t, x) = 0$. In all these cases

$$
\Phi(a(x), x)a'(x) = \Phi(b(x), x)b'(x) = 0,
$$

and as a result we get

$$
\frac{d}{dx} \int_{a(x)}^{b(x)} \sqrt{\Phi(t, x)} \, dt = \int_{a(x)}^{b(x)} \frac{t\alpha - \beta - x}{\sqrt{\Phi(t, x)}} \, dt
$$

and

$$
\psi'(x) = \frac{d}{dx} \int_{I_x} \sqrt{\Phi(t, x)} \, dt = \int_{I_x} \frac{t\alpha - \beta - x}{\sqrt{\Phi(t, x)}} \, dt.
$$

Using the triangle inequality and the change of variables $(u, v) = T(t, x) = (t, t\alpha - \beta - x)$ we obtain

$$
\int_{\text{pr}_2 \mathcal{D}_{\alpha_0, \beta_0}} |\psi'(x)| \, dx = \iint_{\mathcal{D}_{\alpha_0, \beta_0}} \frac{|t\alpha - \beta - x|}{\sqrt{1 + t^2 - (\beta - t\alpha + x)^2}} \, dt \, dx \leq \iint_{\mathcal{D}_{\alpha_0, \beta_0}} \frac{|x|}{\sqrt{1 + u^2 - v^2}} \, du \, dv
$$

$$
= \sqrt{2} + \ln(1 + \sqrt{2}).
$$

(ii) The same change of variable as in (i) gives

$$
\iint_{\mathcal{D}_{\alpha_0, \beta_0}} \sqrt{\Phi(t, x)} \, dt \, dx = \iint_{\mathcal{D}_{\alpha_0, \beta_0}} \sqrt{1 + u^2 - v^2} \, du \, dv = \frac{2\pi}{3}.
$$

□
We start to evaluate $S_Q$. If $D \in J_{q,a}$, then $D \in \Omega_q = (- (2 + r_0 \sqrt{2})q, (2 + r_0 \sqrt{2})q)$. The equality $aq' - a'q = D$ is equivalent to $a' = \frac{aq' - D}{q}$. Hence in the inner sum we should sum over $q' \in [q, Q]$ such that $aq' = D \pmod{q}$ and

$$a \leq \frac{aq' - D}{q} \leq Q,$$

or equivalently

$$(4.5) \quad \max \left\{ q, q + \frac{D}{a} \right\} \leq q' \leq \min \left\{ Q, \frac{qQ + D}{a} \right\}.$$

Next we show that the bulk of the contribution to $S_Q$ of (4.5) only comes from

$$q \leq q' \leq Q.$$

To see this, notice first that for $q'$ fixed, the relations $D = aq' \pmod{q}$ and $|D| \leq (r_0 + \sqrt{2})q$ imply that $D$ takes at most $3 + \lfloor r_0 \rfloor$ values. So the total contribution of terms with $0 \leq q - a \leq 2 + \lfloor r_0 \rfloor$ to $S_Q$ is

$$\ll \frac{1}{Q^4} \sum_{q=1}^{Q} \sum_{q'=1}^{Q} (3 + \lfloor r_0 \rfloor) \cdot \frac{(q' - q)q'}{q^2} \cdot \sqrt{2}r_0q \ll r_0 \frac{1}{Q} \sum_{q=1}^{Q} \frac{1}{q} \ll \frac{\ln Q}{Q}.$$

When $q - a \geq 3 + \lfloor r_0 \rfloor$, we get $-D \leq (3 + \lfloor r_0 \rfloor)Q \leq (q - a)Q$, thus $Q \leq \frac{qQ + D}{a}$. Suppose now that $q'$ is between $q$ and $q + \frac{D}{a}$. Owing again to $aq' = D \pmod{q}$, it follows that $aq' = D + kq$ for some integer $k$. But the range of $q'$ is an interval of length $\lfloor \frac{|D|}{a} \rfloor$, hence the range of $k = \frac{aq'}{q} - \frac{D}{q}$ is an interval of length $\ll 1 + \frac{a}{q} \cdot \frac{|D|}{a} \leq 4 + \lfloor r_0 \rfloor$. Thus $k$, and consequently $q'$, take at most $O(1)$ values. Besides, in this case we have $0 \leq q' - q \leq \lfloor \frac{|D|}{a} \rfloor$. Hence the contribution to $S_Q$ of terms with $q'$ between $q$ and $q + \frac{D}{a}$ is

$$\ll \frac{1}{Q^4} \sum_{1 \leq a \leq q \leq Q} \sum_{D \in \Omega_q} \frac{|D|}{a} \cdot \frac{q}{q^2} = \frac{1}{Q^4} \sum_{1 \leq a \leq q \leq Q} \frac{1}{a} \sum_{D \in \Omega_q} |D| \ll \frac{1}{Q^4} \sum_{a=1}^{Q} \sum_{q=1}^{Q} \frac{1}{a} q^2 \ll \frac{\ln Q}{Q}.$$

Therefore we have shown that we can replace the summation conditions in the inner sum from (4.2) by $q' \in [q, Q]$ and $aq' = D \pmod{q}$.

We write $x_0 = r_0a_0$ and $y_0 = r_0b_0$. Take $D = D_{a_0, b_0}$, $\Phi = \Phi_{a_0, b_0}$ and $\psi = \psi_{a_0, b_0}$, unless otherwise specified, and note that

$$r_0^2(q^2 + a^2) - (y_0q - x_0a + D)^2 = r_0^2q^2 \left( \frac{a}{q} \cdot \frac{D}{r_0q} \right).$$
Then \( \text{(4.1)} \) and the previous considerations lead to

\[
S_Q = \frac{2^r_0}{Q^4} \sum_{0 \leq a \leq Q} \sum_{D \in r_0q^0 J_y} \sum_{q' \in [q, Q]} \sum_{a' \equiv D (\text{mod } q)}^{(q' - q)q'} q' \left( \frac{\Phi \left( \frac{a}{q}, \frac{D}{r_0q} \right)}{q} \right) + O(Q^{-1} \ln Q)
\]

\[
= \frac{2^r_0}{Q^4} \sum_{q=1}^{Q} 1 \sum_{D \in r_0q^0 J_y} \sum_{q' \in [q, Q]} \sum_{a \in \mathcal{I} J_y}^{(q' - q)q'} q' \left( \frac{\Phi \left( \frac{a}{q}, \frac{D}{r_0q} \right)}{q} \right) + O(Q^{-1} \ln Q),
\]

where \( I_x \) and \( J_t \) are defined as in (4.3) and (4.4).

Take \( d = \gcd(q, q') \) and write \( q = d q_0, q' = d q_0'. \) Then \( d \) divides \( D, \) so \( D = d D_0. \) The congruence \( a d q_0' = D \) (mod \( dq_0 \)) is equivalent to \( a d q_0' = D_0 \) (mod \( dq_0 \)), and we may write

\[
(4.6) \quad S_Q = \frac{2^r_0}{Q^4} \sum_{d} \sum_{q_0=1}^{Q} \frac{d}{q_0} \sum_{D_0 \in r_0q^0 J_y} \sum_{q_0' \in \left[ q_0, \frac{Q}{d} \right]} \sum_{a \in \mathcal{I} J_y} \sum_{D_0' \equiv D (\text{mod } q_0')}^{(q_0' - q_0)q_0'} q_0' \left( \frac{\Phi \left( \frac{a}{d q_0}, \frac{D_0}{r_0q_0} \right)}{q_0} \right) + O(Q^{-1} \ln Q).
\]

To estimate the inner sum above, we need some information about the distribution of solutions of the congruence \( xy = h(\text{mod } q). \) We shall employ the following result, which is a consequence of Proposition 6.4 from the Appendix.

**Proposition 4.4.** Assume that \( q \geq 1 \) and \( h \) are two given integers, \( I \) and \( J \) are intervals, and \( f : \mathcal{I} \times \mathcal{J} \to \mathbb{R} \) is a \( C^1 \) function. Then for every integer \( T > 1 \) and every \( \delta > 0 \)

\[
\sum_{a \in \mathcal{I}, b \in \mathcal{J}} f(a, b) = \frac{\varphi(q)}{q^2} \int_{\mathcal{I} \times \mathcal{J}} f(x, y) dxy + O_{\delta} \left( \left( 1 + \frac{|\mathcal{I}|}{q} \right) \left( 1 + \frac{|\mathcal{J}|}{q} \right) T^2 \|f\|_\infty q^{\frac{1}{2} + \delta} \gcd(h, q) \right.
\]

\[
+ \left. \left( 1 + \frac{|\mathcal{I}|}{q} \right) \left( 1 + \frac{|\mathcal{J}|}{q} \right) T \|Df\|_\infty q^{\frac{1}{2} + \delta} \gcd(h, q) + \frac{|\mathcal{I}| |\mathcal{J}| \|Df\|_\infty}{T} \right),
\]

where \( \| \cdot \|_\infty = \| \cdot \|_{\infty, \mathcal{I} \times \mathcal{J}}. \)

We now return to the formula for \( S_Q \) given in (4.6) and first give an upper bound for the contribution to \( S_Q \) of quadruples \((d, q_0, D_0, a)\) for which

\[
0 \leq r_0^2 d^2 q_0^2 \Phi \left( \frac{a}{d q_0}, \frac{D_0}{r_0q_0} \right) = r_0^2 (a^2 + d^2 q_0^2) - (d q_0 y_0 - ax_0 + d D_0)^2 \leq L^2,
\]

with \( L = L_{q_0} > 1 \) to be chosen later.
Lemma 4.5. Let $F(a) = ua^2 + va + w$ with $u \neq 0$. Then for any $K$ and $L$
\[ \left| \{ a \in \mathbb{R} : K \leq F(a) \leq K + L^2 \} \right| \leq \frac{2|L|}{\sqrt{|u|}}. \]

Proof. Using
\[ \{ a : K \leq F(a) \leq K + L^2 \} = \{ a : -K - L^2 \leq -F(a) \leq -K \} \]
we see that it suffices to consider the case $u > 0$. In this case the statement follows from the fact that the double inequality $K \leq F(t) \leq K + L^2$ is equivalent to
\[ \frac{1}{u} \left( K + \frac{v^2 - 4uw}{4u} \right) \leq \left( a + \frac{v}{2u} \right)^2 \leq \frac{L^2}{u} + \frac{1}{u} \left( K + \frac{v^2 - 4uw}{4u} \right), \]
and from the inequality
\[ |\sqrt{x} - \sqrt{y}| \leq \sqrt{|x - y|}. \]

Suppose that $(d, q_0, D_0)$ is fixed and consider the following two cases:

Case 1) $r_0 \neq x_0$.

By (4.7) and Lemma 4.5, the range of $a$ is the union of at most two intervals of length $\frac{L_{q_0}}{r_0}$. Hence $a$ can only assume $O(L_{q_0})$ values. But, for each $a$, $q_0$ belongs to $[q_0, \frac{Q}{d}]$ and is subject to the condition $q_0 a = D_0 (\text{mod } q_0)$. Hence $q_0$ takes $O(1 + \frac{Q}{dq_0}) = O(\frac{Q}{dq_0})$ values. Thus the contribution to $S_Q$ of quadruples $(d, q_0, D_0, a)$ which satisfy (4.7) is
\[ \ll \frac{1}{Q^4} \sum_{d} \sum_{q_0} \frac{d}{q_0} \sum_{|D_0| < q_0} L_{q_0} \cdot \frac{Q}{dq_0} \left( \frac{Q}{d} \right)^2 L_{q_0} \cdot \frac{L_{q_0}}{dq_0} \ll \frac{1}{Q} \sum_{q_0} \frac{L_{q_0}^2}{q_0}. \]

Case 2) $r_0 = x_0$ thus $a_0 = 1$.

In this case we collect directly from (4.7)
\[ \frac{(dq_0y_0 + dD_0)^2 - r_0^2d^2q_0^2}{2r_0d(D_0 + q_0y_0)} \leq a \leq \frac{L^2 + (dq_0y_0 + dD_0)^2 - r_0^2d^2q_0^2}{2r_0d(D_0 + q_0y_0)}. \]

Hence $a$ can only assume $O\left( \frac{L_{q_0}}{dD_0} \right)$ values and we find, arguing as in Case 1, that the contribution to $S_Q$ of quadruples $(d, q_0, D_0, a)$ which satisfy (4.7) is
\[ \ll \frac{1}{Q^4} \sum_{d} \sum_{q_0} \frac{d}{q_0} \sum_{|D_0| < q_0} \frac{L_{q_0}^2}{dD_0} \cdot \frac{Q}{dq_0} \left( \frac{Q}{d} \right)^2 \frac{L_{q_0}}{dq_0} \ll \frac{1}{Q} \sum_{q_0=1}^{Q} \frac{\log q_0}{q_0^3} \cdot L_{q_0}^3 \ll \frac{1}{Q} \sum_{q_0=1}^{Q} \frac{L_{q_0}^3}{q_0^{3-\delta}}. \]

Next we investigate the case
\[ r_0^2d^2q_0^2\Phi\left( \frac{a}{dq_0}, \frac{D_0}{r_0q_0} \right) = r_0^2(a^2 + d^2q_0^2) - (dq_0y_0 - ax_0 + dD_0)^2 \geq L^2. \]
We consider the range of $q_0'$:

$$\mathcal{I}_{q_0,d} = \left[ q_0, \frac{Q}{d} \right],$$

the range of $a$ (which is the union of at most two intervals):

$$\mathcal{J}_{q_0,D_0,d,L} = \left\{ y \in [0, dq_0] : \Phi \left( \frac{y}{dq_0}, \frac{D_0}{r_0 q_0} \right) \geq \frac{L^2}{r_0^2 d^2 q_0} \right\} \subseteq dq_0 I_{D_0, r_0 q_0},$$

and the functions

$$G(x) = G_{q_0}(x) := (x - q_0)x, \quad x \in \mathcal{I}_{q_0,d},$$

$$\Psi(y) = \Psi_{q_0,D_0,d}(y) := \sqrt{\Phi \left( \frac{y}{dq_0}, \frac{D_0}{r_0 q_0} \right)}, \quad y \in \mathcal{J}_{q_0,D_0,d,L} \subseteq [0, dq_0],$$

$$F(x,y) = F_{q_0,D_0,d}(x,y) := G(x) \Psi(y), \quad (x,y) \in \mathcal{I}_{q_0,d} \times \mathcal{J}_{q_0,D_0,d,L}.$$

With this notation the following estimates hold on $\mathcal{I}_{q_0,d} \times \mathcal{J}_{q_0,D_0,d,L}$:

$$\|G\|_{\infty} \ll \frac{Q^2}{d^2}, \quad \|\Psi\|_{\infty} \ll 1, \quad \|F\|_{\infty} \leq \|G\|_{\infty} \|\Psi\|_{\infty} \ll \frac{Q^2}{d^2},$$

$$\|G'\|_{\infty} \ll \frac{Q}{d}, \quad \|\Psi'\|_{\infty} = \sup_{y \in \mathcal{J}_{q_0,D_0,d,L}} \frac{\left| (1 - \alpha_0^2) y + \frac{\alpha_0}{dq_0} \left( \frac{D_0}{r_0 q_0} + \beta_0 \right) \right|}{\sqrt{\Phi \left( \frac{y}{dq_0}, \frac{D_0}{r_0 q_0} \right)}} \ll \frac{1}{L_{q_0}} = \frac{1}{L_{q_0}},$$

$$\|DF\|_{\infty} \leq \|G\|_{\infty} \|\Psi'\|_{\infty} + \|G'\|_{\infty} \|\Psi\|_{\infty} \ll \frac{Q^2}{d^2} \cdot \frac{1}{L_{q_0}} + \frac{Q}{d} = \frac{Q^2}{d L_{q_0}} \left( \frac{1}{d} + \frac{L_{q_0}}{Q} \right) \leq \frac{Q^2}{d L_{q_0}} \left( \frac{1}{d} + \frac{q_0}{Q} \right) \ll \frac{Q^2}{d^2 L_{q_0}}.$$

Applying Proposition 1.2.1 we find that

$$\sum_{q_0' \in \left[ \frac{q_0}{q_0}, \frac{Q}{q_0} \right]} \left( q_0' - q_0 \right) q_0 \sqrt{\Phi \left( \frac{a}{dq_0}, \frac{D_0}{r_0 q_0} \right)} = \sum_{q_0' \in \left[ \frac{q_0}{q_0}, \frac{Q}{q_0} \right]} G_{q_0}(q_0') \Psi_{q_0,D_0,d}(a)$$

$$= \frac{\varphi(q_0)}{q_0^2} \int_{q_0}^{Q/q_0} G_{q_0}(x) \, dx \int_{\mathcal{J}_{q_0,D_0,d,L}} \Psi_{q_0,D_0,d}(y) \, dy + \mathcal{E}_{q_0,D_0,d,L},$$
where

\[ E_{q_0, D_0, d, L} \ll_{\delta} \frac{Q}{dq_0} \cdot dT^2 q_0^{\frac{1}{2} + \delta} \cdot \frac{Q^2}{d^2} \cdot \gcd(D_0, q_0) + \frac{Q}{dq_0} \cdot dT q_0^{\frac{3}{2} + \delta} \cdot \frac{Q^2}{d^2 L} \gcd(D_0, q_0) \]

\[ = \frac{Q^3}{d^2 q_0} \left( T^2 q_0^{\frac{1}{2} + \delta} \gcd(D_0, q_0) + \frac{T q_0^{\frac{3}{2} + \delta}}{L} \gcd(D_0, q_0) + q_0^3 \right). \]

Using

\[ \sum_{|D_0| \ll q_0} \gcd(D_0, q_0) \ll_{\delta} q_0^{1+\delta}, \]

we see that

\[ \sum_{|D_0| \ll q_0} E_{q_0, D_0, d, L} \ll_{\delta} \frac{Q^3}{d^2 q_0} \left( T^2 q_0^{\frac{1}{2} + \delta} + \frac{T q_0^{\frac{3}{2} + \delta}}{L} + q_0^3 \right). \]

Taking \( T = \left[ q_0^{\frac{1}{3}} \right] \) and \( L = \frac{q_0}{10} \) we find that

\[ \sum_{|D_0| \ll q_0} E_{q_0, D_0, d, L} \ll_{\delta} \frac{Q^3}{d^2 q_0} \cdot d_0 \cdot q_0^{1-\frac{1}{10}+\delta} = \frac{Q^3}{d^2} \cdot q_0^{1-\frac{1}{10}+\delta}. \]

Thus the total contribution of \( E_{q_0, D_0, d, L} \) to \( S_Q \) is

\[ \ll_{\delta} \frac{1}{Q} \sum_{d=1}^{Q} \sum_{q_0=1}^{Q} \frac{d}{q_0} \cdot \frac{1}{d^2} \cdot q_0^{1-\frac{1}{10}+\delta} \ll Q^{-\frac{1}{10}+2\delta}. \]

Moreover, the quantities in (4.8) and (4.9) become

\[ \ll \frac{1}{Q} \sum_{q_0=1}^{Q} q_0^{-\frac{1}{10}+\delta} \ll \frac{Q^{\frac{1}{10}}}{Q} = Q^{-\frac{1}{10}} \leq Q^{-\frac{1}{10}}, \]

and respectively

\[ \ll \frac{1}{Q} \sum_{q_0=1}^{Q} q_0^{-\frac{3}{10}+\delta} \ll \frac{Q^{\frac{3}{10}}}{Q} = Q^{-\frac{3}{10}} \leq Q^{-\frac{3}{10}}. \]

Thus we gather

(4.10) \[ S_Q = M_Q + O_{\delta}(Q^{-\frac{1}{10}+\delta}), \]

with

\[ M_Q = \frac{2r_0}{Q^2} \sum_{d} \sum_{q_0=1}^{Q} \frac{d}{q_0} \int_{q_0 D_0 \in r_0 q_0 \mathbb{P}_2 \mathbb{D}} \frac{\varphi(q_0)}{q_0^3} \int_{q_0} G_{q_0}(x) \, dx \int_{\Psi_{q_0, D_0, d}(y)} J_{q_0, D_0, d, q_0/10} \Psi_{q_0, D_0, d}(y) \, dy. \]
Next we show that we can replace \( J_{q_0, D_0, d, q_0^{9/10}} \) by \( dq_0 I_{D_0} \) in the last integral. Clearly \( J_{q_0, D_0, d, q_0^{9/10}} \subseteq dq_0 I_{D_0} \) and by Lemma 4.5 we have

\[
\left| dq_0 I_{D_0} \setminus J_{q_0, D_0, d, q_0^{9/10}} \right| \ll 2 \sqrt{\frac{(q_0^{9/10})^2}{r_0^2 - x_0^2}} \ll q_0^{9/5}.
\]

Thus

\[
0 \leq \int_{dq_0 I_{D_0} \setminus J_{q_0, D_0, d, q_0^{9/10}}} \Psi_{q_0, D_0, d}(y) \, dy \leq \left| dq_0 I_{D_0} \setminus J_{q_0, D_0, d, q_0^{9/10}} \right| \cdot q_0^{9/10} \ll q_0^{4/5} \frac{d}{d},
\]

and as a result the error that results from replacing \( J_{q_0, D_0, d, L} \) by \( dq_0 I_{D_0} \) in \( M_Q \) is

\[
\ll \frac{1}{Q^4} \sum_{d} \sum_{q_0 = 1}^{Q} \frac{\phi(q_0)}{q_0^3} \cdot q_0^{4/5} \int_{q_0} G_{q_0}(x) \, dx.
\]

On the other hand we find that

\[
\int_{q_0} G_{q_0}(x) \, dx = \int_{0}^{q_0} \int_{0}^{x + q_0} \, dx = q_0^3 \cdot q_0 \frac{Q}{dq_0},
\]

where

\[
g(t) = \frac{(t - 1)^3}{3} + \frac{(t - 1)^2}{2}.
\]

In particular, the integral of \( G_{q_0} \) on \( [q_0, \frac{Q}{d}] \) is \( \ll \frac{Q^3}{d^3} \), and we find that the total cost of replacing \( J_{q_0, D_0, d, q_0^{9/10}} \) by \( dq_0 I_{D_0} \) in \( M_Q \) is

\[
\ll \frac{1}{Q^4} \sum_{d} \sum_{q_0 = 1}^{Q} \frac{\phi(q_0)}{q_0^3} \cdot \frac{Q^3}{d^3} \cdot q_0^{-6} \ll \frac{1}{Q}.
\]
Thus we infer that

\[ M_Q = \frac{2r_0}{Q^4} \sum_d \sum_{q_0=1}^{[\frac{Q}{q}]} \frac{d}{q_0} \cdot \varphi(q_0) \frac{g(Q)}{dq_0} \cdot \sum_{D_0 \in r_0q_0pr_2D} \int_{\frac{D_0}{r_0q_0}} \Psi_{q_0,D_0,q}(y) \, dy + O(Q^{-1}) \]

(4.11)

\[ = \frac{2r_0}{Q^4} \sum_d \sum_{q_0=1}^{[\frac{Q}{q}]} d^2 q_0 \varphi(q_0) g\left(\frac{Q}{dq_0}\right) \sum_{D_0 \in r_0q_0pr_2D} \int_{\frac{D_0}{r_0q_0}} \Phi\left(\frac{y}{dq_0}, \frac{D_0}{r_0q_0}\right) \, dy + O(Q^{-1}) \]

By Euler-MacLaurin summation and Lemma 4.3, the inner sum above is given by

\[ \int_{r_0q_0pr_2D} \psi\left(\frac{u}{r_0q_0}\right) \, du + O\left(\sup_{x \in pr_2D} |\psi(x)| + \int_{r_0q_0pr_2D} \left| \frac{1}{r_0q_0} \cdot \psi'\left(\frac{u}{r_0q_0}\right) \right| \, du \right) \]

\[ = r_0q_0 \int_{pr_2D} \psi(v) \, dv + O(1) = \frac{2\pi r_0q_0}{3} + O(1). \]

Inserting this back into (4.11) we obtain

\[ M_Q = \frac{4\pi r_0^2}{3Q^4} \sum_d \sum_{q_0=1}^{[\frac{Q}{q}]} \varphi(q_0)(dq_0)^2 g\left(\frac{Q}{dq_0}\right) + O\left(\frac{\ln Q}{Q}\right) \]

\[ (q = dq_0 \in [1, Q]) \]

(4.12)

\[ = \frac{4\pi r_0^2}{3Q^4} \sum_{q=1}^{Q} q^2 g\left(\frac{Q}{q}\right) \sum_{q_0|q} \varphi(q_0) + O\left(\frac{\ln^2 Q}{Q}\right) \]

Proposition 4.1 now follows from (4.10) and (4.12).
5. On the 6-level correlations

In this section we prove Theorem 1.2. We first prove a counting result.

**Lemma 5.1.** Let \(a, b, d\) be positive integers with \(\gcd(a, b, d) = 1\). Let \(d_1\) denote the largest divisor of \(d\) which is relatively prime with \(b\), and put \(d_2 = \frac{d}{d_1}\). Then

\[
\#\{0 \leq m \leq 2d - 1 : \gcd(a + bm, d) = 1\} = 2\varphi(d_1)d_2.
\]

**Proof.** Using Möbius inversion we express the left-hand side of (5.1) as

\[
\sum_{0 \leq m \leq 2d - 1} \sum_{\substack{D \mid d \backslash (a + bm) \in \mathbb{Z} \backslash 0}} \mu(D) = \sum_{D \mid d} \mu(D) \#\{0 \leq m \leq 2d - 1 : D \mid a + bm\}.
\]

Note that if \(D\) does not divide \(d_1\), then there is no \(m\) for which \(D \mid a + bm\). Indeed, if for some \(m\) we have \(D \mid a + bm\), then \(a = Dk - bm\) for some \(k \in \mathbb{Z}\). Hence \(a\) is divisible by \(\gcd(D, b)\). Then \(\gcd(D, b)\) divides \(\gcd(a, b, d) = 1\), so \(\gcd(D, b) = 1\), and by the definition of \(d_1\) it follows that \(D\) divides \(d_1\). Therefore

\[
\#\{0 \leq m \leq 2d - 1 : \gcd(a + bm, d) = 1\} = \sum_{D \mid d_1} \mu(D) \#\{0 \leq m \leq 2d - 1 : D \mid a + bm\}.
\]

For \(D \mid d_1\) we have \(\gcd(D, b) = 1\) and there is a unique solution \(m \pmod{D}\) to the congruence \(a + bm = 0 \pmod{D}\). Thus there are exactly \(\frac{2d}{D}\) values of \(m\) in \(\{0, 1, \ldots, 2d - 1\}\) for which \(D \mid a + bm\). As a result we infer that

\[
\#\{0 \leq m \leq 2d - 1 : \gcd(a + bm, d) = 1\} = \sum_{D \mid d_1} \mu(D) \frac{2d}{D} = 2d \sum_{D \mid d_1} \frac{\mu(D)}{D} = 2d \frac{\varphi(d_1)}{d_1} = 2\varphi(d_1)d_2,
\]

which proves the lemma. \(\Box\)

For any positive integers \(a, b, q\), consider the set

\[
\mathcal{N}_{a, b, q} = \{(A, B) : 1 \leq A, B \leq 2q, \gcd(A, B) = 1, \ q \mid Ab - Ba\}.
\]

**Lemma 5.2.** For \(q\) large and \(1 \leq a, b \leq q\) such that \(\gcd(a, b, q) = 1\)

\[
\#\mathcal{N}_{a, b, q} \gg \frac{\varphi(q)}{\ln q} \gg \frac{q}{\ln q \ln \ln q}.
\]
Remark. If in the definition of \( N_{a,b,q} \) we took the range of \( A \) and \( B \) to be \([1,q]\) instead of \([1,2q]\), the cardinality of \( N_{a,b,q} \) would be much smaller. For example, if \( 1 \leq a \leq q \), \( \gcd(a,q) = 1 \), and \( b = a \), then \( q | A - B \), and in the range \( 1 \leq A, B \leq q \) this forces \( A = B \). Then the only pair \((A,B)\) with \( \gcd(A,B) = 1 \) is \((1,1)\), so \( N_{a,b,q} \) will only contain one element. Lemma 5.2 shows a sudden increase in the cardinality of \( N_{a,b,q} \) when the range of \( A \) and \( B \) increases by a factor 2.

Proof of Lemma 5.2. To make a choice, assume in what follows next that \( d = \gcd(a,q) \leq \gcd(b,q) \). Then \( \gcd(d,b) = 1 \) since \( \gcd(q,a,b) = 1 \). It follows that for any solution \((A,B)\) to the congruence \( Ab = Ba \pmod{q} \), \( A \) has to be divisible by \( d \). Write \( q = dq_1 \) and \( a = da_1 \), so \( \gcd(a_1,q_1) = 1 \). Denote by \( \bar{a}_1 \) the multiplicative inverse of \( a_1 \pmod{q_1} \) in the interval \([1,q_1]\).

Note that since \( q \) is divisible by the product \( \gcd(a,q) \gcd(b,q) \), we have \( d < \sqrt{q} \). Therefore \( q_1 > \sqrt{q} \). So \( q_1 \) is large for large \( q \), and by the Prime Number Theorem we know that

\[
\#\{p \text{ prime : } q_1 < p \leq 2q_1\} \sim \frac{q_1}{\ln q_1}.
\]

For any fixed prime \( p \) with \( q_1 < p \leq 2q_1 \), we count the solutions \( 1 \leq B \leq 2q_1 \) of the congruence

\[(5.3)\quad dpb = Ba \pmod{q}.
\]

This is equivalent to

\[(5.4)\quad pb = Ba_1 \pmod{q_1}.
\]

Since \( \gcd(q_1,a_1) = 1 \), this congruence has a unique solution modulo \( q_1 \), namely \( B = \bar{a}_1 pb \pmod{q_1} \). Denote by \( B_0 \) the solution to \( (5.4) \) which belongs to the interval \([1,q_1]\). Then \( (5.3) \) will have \( 2d \) solutions, given by

\[(5.5)\quad B = B_0 + q_1 m, \quad 0 \leq m \leq 2d - 1.
\]

It remains to be seen how many of the numbers \( B \) from \((5.5)\) are relatively prime with \( A = dp \). Note first that at most two such numbers \( B \) are divisible by \( p \). Assume that

\[(5.6)\quad p | B_0 + q_1 m_1, \quad p | B_0 + q_1 m_2, \quad \text{and} \quad p | B_0 + q_1 m_3,
\]

with \( 0 \leq m_1 < m_2 < m_3 \leq 2d - 1 \). Since \( p > q_1 \), \( p \) does not divide \( q_1 \). Then it follows from \((5.6)\) that

\[(5.7)\quad p | m_2 - m_1 \quad \text{and} \quad p | m_3 - m_2.
\]

Here at least one of the differences \( m_2 - m_1, m_3 - m_2 \) is less than \( d \), and \( d < \sqrt{q} < q_1 < p \), so it is impossible that both divisibilities in \((5.7)\) hold true. Therefore at most two numbers
from (5.5) are divisible by $p$. Note also, by the same reasoning, that for smaller values of $d$ - more precisely for $d < \sqrt{q}$, that is $d < \frac{q}{2}$ - one has $2d < p$. Then one concludes that at most one number $B$ from (5.5) can be a multiple of $p$.

We now count the numbers $B$ from (5.5) which are relatively prime with $d$. We claim that $\gcd(B_0, q_1, d) = 1$. Indeed, let us assume this fails and choose a prime divisor $p_1$ of $\gcd(B_0, q_1, d)$. Since $p_1 | d$, we have $p_1 | a$ and $p_1 | q_1$. Recall that $B_0$ satisfies (5.4), hence

$$pb = B_0a_1 + q_1k$$

for some $k \in \mathbb{Z}$. Here $p_1 | B_0$, $p_1 | q_1$, so $p_1$ must also divide the left side of (5.8). The inequalities $p_1 \leq B_0 \leq q_1 < p$ show that $p_1 \neq p$, so $p$ divides $b$. But then $p_1 | \gcd(a, b, q) = 1$, and we obtain a contradiction. This shows that $\gcd(B_0, q_1, d) = 1$. Then Lemma 5.1 is applicable to $B_0, q_1, d$. If $d_1$ denotes the largest divisor of $d$ which is relatively prime with $q_1$, and $d_2 = \frac{d}{d_1}$, then Lemma 5.1 provides

$$\# \{0 \leq m \leq 2d - 1 : \gcd(B_0 + q_1m, d) = 1\} = 2\varphi(d_1)d_2.$$ 

It follows in particular that there are always at least two numbers $B$ as in (5.5) for which $\gcd(B, d) = 1$, and as soon as $d_2 \geq 2$ or $d_1 \geq 3$, there are at least four such numbers. Since at most two numbers $B$ as in (5.5) are divisible by $p$, and for small values of $d$ we know that at most one number $B$ as in (5.5) is divisible by $p$, we conclude that in all cases we have

$$\# \{1 \leq B \leq 2d : \gcd(B, dp) = 1, \ dpb = Ba \ (\text{mod} \ q)\} \geq \varphi(d_1)d_2 \geq \varphi(d).$$  

Combining (5.9) with (5.2) we infer that

$$\# \mathcal{N}_{a,b,q} \gg \frac{q \varphi(d)}{\ln q_1} \geq \frac{q \varphi(d)}{\ln q} \cdot \frac{\varphi(d)}{d},$$

and the lemma is completed using the inequalities

$$\frac{\varphi(d)}{d} \geq \frac{\varphi(q)}{q} \gg \frac{1}{\ln \ln q}.$$ 

Let now $q$ be a large positive integer, let $a, b \in \{1, \ldots, q\}$ such that $\gcd(a, b, q) = 1$, and let $Q$ be a positive integer larger than $q$. In our applications $Q$ will be at least of the order of magnitude of $q^4$. We will construct some sets of lattice points inside the square $[0, Q]^2$, indexed by the set $\mathcal{N}_{a,b,q}$. Precisely, we select a positive integer $M$, which will be chosen later to be the integer part of a certain fractional power of $Q$, and for each pair $(A, B) \in \mathcal{N}_{a,b,q}$ we construct a set $\mathcal{M}_{A,B} = \mathcal{M}_{A,B}(a, b, q, Q, M)$ as follows. Fix $(A, B) \in \mathcal{N}_{a,b,q}$. To make a choice assume that $B \leq A$. Let $C$ be the integer defined by the equation

$$bA - aB = qC.$$
Denote by $u$ the unique integer satisfying
$$u = -\overline{B}C \pmod{A}, \quad 0 \leq u \leq A - 1,$$
where $\overline{B}$ is the multiplicative inverse of $B$ modulo $A$, and put $v = \frac{Bu+C}{A}$. Then $v$ is an integer. Also, from the inequalities
$$-B \leq -\frac{ab}{q} < \frac{bA-ab}{q} = C < \frac{bA}{q} \leq A$$
it follows that $\frac{C}{A} \in (-\frac{B}{A}, 1) \subseteq (-1, 1)$. Hence
$$-1 < \frac{C}{A} \leq \frac{Bu+C}{A} \leq \frac{Bu}{A} + 1 < B + 1,$$so that $v \in (-1, B + 1)$. Thus $0 \leq v \leq B$, since $v$ is an integer. Let now $s = \left[\frac{Q}{A}\right]$, and define $M_{A,B}$ to be the set of lattice points given by
$$M_{A,B} = \{(u + mA, v + mB) : s - M \leq m \leq s - 1\}.$$Note that the case $A = B$ can only occur when $a = b$, and in this situation we also get $C = 0$, $u = v = 0$, and so $M_{0,0} = \{(mA, mA) : s - M \leq m \leq s - 1\}$. We have constructed $\#N_{a,b,q}$ sets of the form $M_{A,B}$, each set $M_{A,B}$ consisting of $M$ lattice points. Note that $u, v, s$ in the definition of $M_{A,B}$ depend on the pair $(A, B)$. In what follows we assume that $M$ satisfies the inequality
(5.11)$$M \leq \left[\frac{Q}{4q}\right].$$Define also
$$\widetilde{M}_{a,b,q} = \bigcup_{(A,B) \in N_{a,b,q}} M_{A,B}.$$Some properties of these sets are collected in the following lemma.

**Lemma 5.3.** (i) $\text{dist}([0,1]^2, \widetilde{M}_{a,b,q}) \geq \frac{Q}{3}$.

(ii) $\widetilde{M}_{a,b,q} \subseteq [0, Q]^2$.

(iii) The sets $M_{A,B}$ are disjoint.

**Proof.** (i) Owing to (5.11) and to the inequality
$$[x] - \left[\frac{x}{2}\right] \geq \frac{x}{2} - 1,$$we have for any $(A, B) \in N_{a,b,q}$ and any point $(u + mA, u + mB) \in M_{A,B}$
$$u + mA \geq mA \geq (s - M)A \geq \left(\left[\frac{Q}{A}\right] - \left[\frac{Q}{4q}\right]\right) A \geq \left(\left[\frac{Q}{A}\right] - \left[\frac{Q}{2A}\right]\right) A \geq \frac{Q}{2} - A \geq \frac{Q}{2} - 2q.$$
Recall that $Q$ is much larger than $q$. It follows that the distance between any two points $P \in [0,1]^2$ and $P' \in \tilde{\mathcal{M}}_{a,b,q}$ satisfies

\begin{equation}
\|PP'\| \geq \frac{Q}{2} - 2q - 1 \geq \frac{Q}{3}.
\end{equation}

(ii) For any $(A,B) \in \mathcal{N}_{a,b,q}$ with, say, $A \geq B$, and any point $P = (u + mA, v + mB) \in \mathcal{M}_{A,B}$, one has $u + mA \leq u + (s - 1)A \leq sA \leq Q$. Also, $0 \leq v + mB \leq v + (s - 1)B \leq sB = \left[\frac{Q}{A}\right]B \leq Q$, since $B \leq A$. Hence all points $P \in \tilde{\mathcal{M}}_{a,b,q}$ lie inside the square $[0,Q]^2$.

(iii) Assume that there is a lattice point $P = (n_1,n_2)$ which belongs to two sets $\mathcal{M}_{A,B}$ and $\mathcal{M}_{A',B'}$ with $(A,B), (A',B') \in \mathcal{N}_{a,b,q}$ and $(A,B) \neq (A',B')$. Assume first that $B \leq A$ and $B' \leq A'$. Then

\begin{equation}
q_2 - b = qv + qmA - a = qu + qmA - a = \frac{qBu + qC + AqmB - Ab}{A(qu + qmA - a)} = \frac{qBu - aB + AqmB}{A(qu + qmA - a)} = \frac{B}{A}.
\end{equation}

By a similar computation we also have

$$\frac{q_2 - b}{q_1 - a} = \frac{B'}{A'} = \frac{B}{A}.$$ 

Since $A, B, A', B'$ are all positive and $\gcd(B, A) = \gcd(B', A') = 1$, this forces $A = A'$ and $B = B'$.

In general we get by the same argument $\min\{A, B\} = \min\{A', B'\}$ and $\max\{A, B\} = \max\{A', B'\}$, thus $(A', B') \in \{(A, B), (B, A)\}$. If $A' = B$ and $B' = A$, we get $\frac{A}{B} = \frac{B}{A}$, hence $A^2 = B^2$ and $A = B = 1$. 

Fix now a point $P(x,y) \in [0,1]^2$ and a pair $(A,B) \in \mathcal{N}_{a,b,q}$. Also, choose any two points $P, P' \in \mathcal{M}_{A,B}$, say $P = (u + mA, v + mB)$ and $P' = (u + m'A, v + m'B)$, with $m,m' \in \mathbb{Z}$.
\( \{ s - M, \ldots, s - 1 \} \). Consider the angle \( \theta = \angle P'P_{(x,y)}P \). Then by (5.12)
\[
| \sin \theta | = \frac{2 \text{Area} \triangle P'P_{(x,y)}P}{\| PP_{(x,y)} \| \| P'P_{(x,y)} \|} \leq \frac{18 \text{Area} \triangle P'P_{(x,y)}P}{Q^2} \]
\[
= \frac{9 |(u + m' x - x)(v + mB - y) - (u + mA - x)(v + m'B - y)|}{Q^2} \]
\[
= \frac{9 |m' - m| \cdot |A(v - y) - B(u - x)|}{Q^2} \]
\[
\leq \frac{9 M |A(v - y) - B(u - x)|}{Q^2}.
\]

Next, using the equality \( v = \frac{Bu + C}{A} \), we rewrite (5.14) as
\[
| \sin \theta | \leq \frac{9 M |C + Bx - Ay|}{Q^2}.
\]

Since \( |C| \leq \max \{ A, B \} \leq 2q \) and \( 0 \leq x, y \leq 1 \), we see that \( |C + Bx - Ay| \ll q \). If \( M \) satisfies (5.11), then \( M |C + Bx - Ay| \ll Q \). As a consequence of (5.15) we also have
\[
| \sin \theta | \ll \frac{1}{Q}.
\]

From (5.15) we also infer that
\[
| \theta | \leq \frac{\pi}{2} | \sin \theta | \ll \frac{M |C + Bx - Ay|}{Q^2}.
\]

By (5.10) and (5.16) we derive that
\[
| \theta | \ll \frac{M |Cq + Bqx - Aqy|}{q Q^2} = \frac{M |A(b - qy) + B(qx - a)|}{q Q^2}.
\]

As a consequence of (5.17) and of the inequalities \( 1 \leq A, B \leq 2q \), we have
\[
| \theta | \ll \frac{M (|b - qy| + |qx - a|)}{Q^2},
\]
uniformly for all pairs \( (A, B) \in \mathcal{N}_{a,b,q} \) and all pairs of points \( P, P' \in M_{A,B} \).

**Proof of Theorem 1.2.** Fix \((x, y) \in [0, 1]^2\), \( \lambda = (\lambda_1, \ldots, \lambda_5) \in \mathbb{R}^5 \) with \( \lambda_1, \ldots, \lambda_5 > 0 \), and \( \delta > 0 \). The case when both \( x \) and \( y \) are rational numbers is clear. In this case, if we fix an integer \( m_0 \geq 1 \) for which both \( m_0 x \) and \( m_0 y \) are integers, and consider the set of lattice points \( \mathcal{A} = \{(\ell m_0 x, \ell m_0 y) : \ell = 1, 2, \ldots, \lfloor \frac{Q}{m_0} \rfloor \} \), then all these points lie on the same line, that passes through \( P_{(x,y)} \). Then all the 6-tuples of distinct elements from \( \mathcal{A} \) will contribute to \( \mathcal{R}^{(6)}_{(x,y),Q}(\lambda) \). Since \( \# \mathcal{A} = \lfloor \frac{Q}{m_0} \rfloor \), it follows that
\[
\mathcal{R}^{(6)}_{(x,y),Q}(\lambda) \gg \frac{1}{\# \mathcal{Q}} \cdot \frac{Q^6}{m_0^6} \gg \frac{Q^4}{m_0^6}.
\]
Note that in this case the 3-level correlations already diverge as \( Q \to \infty \).
Consider now the case when at least one of $x, y$ is irrational. With $x, y, \lambda$ and $\delta$ fixed, choose a large positive integer $Q$. Let $1 < T < Q$ be a parameter, whose precise value will be chosen later and will be the integer part of a fractional power of $Q$. By Minkowski’s convex body theorem (see [7, Thm. 6.25] for the formulation used here), there exists an integer $1 \leq q \leq T$ for which

\begin{equation}
\langle qx \rangle \leq \frac{1}{\sqrt{T}} \quad \text{and} \quad \langle qy \rangle \leq \frac{1}{\sqrt{T}},
\end{equation}

where $\langle \cdot \rangle$ denotes here the distance to the closest integer. Let $a$ and $b$ denote the closest integers to $qx$ and $qy$ respectively. Then $0 \leq a, b \leq q$, $\max\{a, b\} > 0$, and (5.19) gives

\begin{equation}
|qx - a| \leq \frac{1}{\sqrt{T}} \quad \text{and} \quad |qy - b| \leq \frac{1}{\sqrt{T}}.
\end{equation}

Dividing if necessary $a, b$ and $q$ by $\gcd(a, b, q)$, we may assume in what follows that $\gcd(a, b, q) = 1$.

We will have $T \to \infty$ as $Q \to \infty$, and since at least one of $x, y$ is irrational, this forces $q \to \infty$ as $Q \to \infty$. Then all our previous results valid for large $q$ are applicable.

Let $M$ be a positive integer satisfying (5.11), whose precise order of magnitude will be chosen later. Consider the disjoint subsets $\mathcal{M}_{A, B}$ of $\square_Q$, with $(A, B) \in \mathcal{N}_{a, b, q}$. By (5.15) we know that for any $(A, B) \in \mathcal{N}_{a, b, q}$ and any $P, P' \in \mathcal{M}_{A, B}$, the measure of the angle $\angle PP'(x, y)\ast P'$ satisfies

\begin{equation}
|\theta_{P, P'}| \ll \frac{M(|b - qy| + |qx - a|)}{Q^2}.
\end{equation}

Plugging (5.20) in (5.21) we find that

\begin{equation}
|\theta_{P, P'}| \ll \frac{M}{Q^2 \sqrt{T}}.
\end{equation}

If we take the order of magnitude of $M$ to be slightly smaller than that of both $\frac{Q}{q}$ and $\sqrt{T}$, for instance

\begin{equation}
M = \min\left\{\left[\frac{Q}{4q}\right], \left[\frac{\sqrt{T}}{\ln Q}\right]\right\},
\end{equation}

then $M$ will satisfy (5.11) on the one hand, and on the other hand we will have

\begin{equation}
|\theta_{P, P'}| \ll \frac{1}{Q^2 \ln Q}.
\end{equation}

It follows that for $Q$ large enough in terms of $\lambda_1, \ldots, \lambda_5$, all the 6-tuples $(P_1, \ldots, P_6)$ of distinct points from $\mathcal{M}_{A, B}$ will contribute to $\mathcal{R}^{(6)}_{(x, y), Q}(\lambda)$. Therefore, since $\#\mathcal{M}_{A, B} = M$ for each $(A, B) \in \mathcal{N}_{a, b, q}$, we derive that

\begin{equation}
\mathcal{R}^{(6)}_{(x, y), Q}(\lambda) \geq \frac{1}{N} \cdot \#\mathcal{N}_{a, b, q} \cdot M(M - 1) \cdots (M - 5).
\end{equation}
Here $N = \#Q = (2Q + 1)^2$, and from (5.22) and Lemma 5.1 it follows that

$$R_{(x,y),Q}(\lambda) \gg \frac{M^6 q}{Q^2 \ln q \ln \ln q} \gg \min \left\{ \frac{Q^4}{q^5 \ln^2 q}, \frac{T^3 q}{Q^2 \ln^8 Q} \right\}. \tag{5.23}$$

We now choose $T = [Q^{\frac{1}{6}}]$. Then, no matter how small $q$ might be, we have

$$\frac{T^3 q}{Q^2 \ln^8 Q} \geq \frac{Q^\frac{1}{2}}{\ln^8 Q} > Q^{\frac{1}{4} - \delta} \quad \text{for large } Q. \tag{5.24}$$

Also, since $q \leq T$, it follows that

$$\frac{Q^4}{q^5 \ln^2 q} \geq \frac{Q^4}{T^5 \ln^2 T} \geq \frac{Q^\frac{1}{2}}{\ln^2 Q} > Q^{\frac{1}{4} - \delta} \quad \text{for large } Q. \tag{5.25}$$

Now (1.4) follows from (5.23), (5.24) and (5.25). \hfill \square

6. Appendix

For a fixed integer $q \geq 2$, we consider for any integers $m, n, h$ and any sets $I, I_1, I_2 \subset \mathbb{R}$ the Kloosterman sum

$$K(m, n; q) = \sum_{x \pmod{q} \gcd(x, q) = 1} e\left(\frac{mx + n\bar{x}}{q}\right),$$

the incomplete Kloosterman sum

$$K(m, n; q) = \sum_{x \in I, \gcd(x, q) = 1} e\left(\frac{mx + n\bar{x}}{q}\right),$$

and the set

$$N_{q,h}(I_1, I_2) = \{(x, y) \in I_1 \times I_2 : \gcd(x, q) = 1, \; xy = h \pmod{q}\}.$$ 

Here $\bar{x}$ denotes the multiplicative inverse of $x \pmod{q}$.

**Lemma 6.1.** ([2, Lemma 2.2]) Suppose that $f$ is a piecewise $C^1$ function on $[a,b]$. Then

$$\sum_{a < k \leq b \gcd(k,q) = 1} f(k) = \frac{\varphi(q)}{q} \int_{a}^{b} f + O\left(q^\epsilon (\|f\|_\infty + V^b_a f)\right).$$

**Lemma 6.2.** ([2, Lemma 1.6]) For any interval $I \subset [0, q]$ and any integer $n$

$$|S_I(0, n, q)| \ll \gcd(n,q)^{\frac{1}{2}} q^{\frac{1}{2} + \epsilon}.$$
Proof. We write

\[ S_I(0, n, q) = \sum_{x \text{ (mod } q)} e\left( \frac{n\bar{x}}{q} \right) \sum_{y \in I} \frac{1}{q} \sum_{k=1}^{q} e\left( \frac{k(y-x)}{q} \right) \]

(6.1)

\[ = \frac{1}{q} \sum_{k=1}^{q} \sum_{y \in I} \frac{e\left( \frac{ky}{q} \right)}{r(x, q)} \sum_{x \text{ (mod } q)} e\left( \frac{-kx + n\bar{x}}{q} \right) \]

\[ = \frac{1}{q} \sum_{k=1}^{q} \sum_{y \in I} \frac{e\left( \frac{ky}{x} \right)}{K(-k, n, q)}. \]

The inner sum is a geometric progression and can be bounded as

(6.2)

\[ \left| \sum_{y \in I} e\left( \frac{ky}{q} \right) \right| \leq \min\left\{ |I|, \frac{1}{2\|k\|} \right\}. \]

By (6.1) and (6.2)

\[ |S_I(0, n, q)| \leq \frac{1}{q} K(0, n, q)|I| + \frac{1}{q} \sum_{k=1}^{q-1} \frac{1}{2\|k\|} K(-k, n, q) \]

\[ \ll \frac{qq^{\frac{1}{2}+\epsilon} \varphi(n, q)^{\frac{1}{2}}}{q} + q^{\frac{1}{2}+\epsilon} \varphi(n, q)q \log q \ll \varphi(n, q)^{\frac{1}{2}} q^{\frac{1}{2}+2\epsilon}. \]

\[ \square \]

Proposition 6.3. Suppose that \( I_1, I_2 \subset [0, q) \) are intervals. Then for any integer \( h \)

\[ N_{q, h}(I_1, I_2) = \frac{\varphi(q)}{q^2} |I_1||I_2| + O_\delta(q^{\frac{1}{2}+\delta} \varphi(h, q)). \]

Proof. We write

\[ N_{q, h}(I_1, I_2) = \frac{1}{q} \sum_{x \in I_1, y \in I_2} \frac{1}{q} \sum_{k=0}^{q-1} e\left( \frac{k(y-h\bar{x})}{q} \right) = M + E, \]

where the main term can be expressed, as a result of Lemma 6.1, as

\[ M = \frac{1}{q} \sum_{x \in I_1, y \in I_2} \frac{1}{q} \left( \varphi(q) \right) |I_1| + O(q^\epsilon) \left( |I_2| + O(1) \right) = \frac{\varphi(q)}{q^2} |I_1||I_2| + O(q^\epsilon). \]

The error is given by

\[ E = \frac{1}{q} \sum_{k=1}^{q-1} \sum_{x \in I_1} \sum_{y \in I_2} e\left( \frac{ky}{q} \right) e\left( -\frac{hk\bar{x}}{x} \right) = \frac{1}{q} \sum_{k=1}^{q-1} \sum_{y \in I_2} e\left( \frac{ky}{x} \right) S_I(0, -hk, q). \]
Owing to (6.2), Lemma 6.2, and to the inequality $\gcd(kh, q) \leq \gcd(h, q) \gcd(k, q)$, we have

$$|E| \leq \frac{\gcd(h, q)^{\frac{1}{2}}}{q} \sum_{k=1}^{q-1} \frac{1}{2\|\frac{k}{q}\|} \gcd(k, q)^{\frac{1}{2}} q^{\frac{1}{2}+\varepsilon} \leq \gcd(h, q)^{\frac{1}{2}} q^{\frac{1}{2}+\varepsilon} \sum_{k=1}^{q-1} \frac{1}{k} \gcd(k, q)^{\frac{1}{2}}.$$

Writing $k = dm$, with $d = \gcd(k, m)$, we eventually get

$$|E| \leq \gcd(h, q)^{\frac{1}{2}} q^{\frac{1}{2}+\varepsilon} \sum_{d|q} \frac{1}{d^2} \sum_{m=1}^{\frac{q}{d}} \frac{1}{m} \ll \gcd(h, q)^{\frac{1}{2}} q^{\frac{1}{2}+2\varepsilon} \log q \ll \gcd(h, q)^{\frac{1}{2}} q^{\frac{1}{2}+3\varepsilon}.$$ 

\[\square\]

**Proposition 6.4.** Assume that $q \geq 1$ and $h$ are two given integers, $I$ and $J$ are intervals of length lesser than $q$, and $f : I \times J \to \mathbb{R}$ is a $C^1$ function. Then for any integer $T > 1$ and any $\delta > 0$

$$\sum_{a \in I, b \in J \atop ab \equiv h \pmod{q} \atop \gcd(b, q) = 1} f(a, b) = \frac{\varphi(q)}{q^{2}} \iint_{I \times J} f(x, y) dxdy$$

$$+ O_\delta \left(T^2 \|f\|_\infty q^{\frac{1}{2}+\delta} \gcd(h, q) + T\|Df\|_\infty q^{\frac{1}{2}+\delta} \gcd(h, q) + \frac{|I| |J| \|Df\|_\infty}{T}\right).$$

The proof is identical to that of Lemma 2.2 in [4], and relies on Proposition 6.3.
