COMPLEX ADJOINT ORBITS IN LIE THEORY AND GEOMETRY

PETER CROOKS

ABSTRACT. This expository article is an introduction to the adjoint orbits of complex semisimple groups, primarily in the algebro-geometric and Lie-theoretic contexts, and with a pronounced emphasis on the properties of semisimple and nilpotent orbits. It is intended to build a foundation for more specialized settings in which adjoint orbits feature prominently (e.g. hyperkähler geometry, Landau-Ginzburg models, and the theory of symplectic singularities). Also included are a few arguments and observations that, to the author’s knowledge, have not yet appeared in the research literature.

1. INTRODUCTION

1.1. Motivation and objectives. In linear algebra, it is a classical exercise to determine whether two given matrices, \( A, B \in \text{Mat}_{n \times n}(\mathbb{C}) \), are conjugate, i.e. whether \( B = QAQ^{-1} \) for some invertible \( Q \in \text{Mat}_{n \times n}(\mathbb{C}) \). More generally, one can fix \( A \in \text{Mat}_{n \times n}(\mathbb{C}) \) and consider the set of all \( B \in \text{Mat}_{n \times n}(\mathbb{C}) \) that are conjugate to \( A \). This set is precisely the conjugacy class of \( A \), and, as we shall see, it is the paradigm example of a complex adjoint orbit. Despite this classical motivation, complex adjoint orbits are central to modern research in algebraic geometry \([5, 6, 23, 24, 33, 39, 45]\), differential geometry \([8, 10, 11, 19, 44, 46, 47]\), Lie theory \([4, 17, 31, 53, 54]\), and geometric representation theory \([12, 16, 38, 55]\).

This article is an introduction to complex adjoint orbits in algebraic geometry, Lie theory, and, to a lesser extent, the other fields mentioned above. It is written with a view to meeting several key objectives. Firstly, it should be accessible to a fairly broad mathematical audience and require only introductory algebraic geometry and Lie theory as prerequisites. Secondly, it aims to build a clear, intuitive, and reasonably self-contained foundation for more advanced topics in which complex adjoint orbits play a role. Thirdly, it is designed to motivate and outline some of these more advanced topics (ex. hyperkähler geometry, Landau-Ginzburg models, and symplectic singularities). Our final objective is to emphasize a few contextually appropriate arguments that, while possibly well-known to experts, do not seem to appear in the research literature. The arguments in question are the proofs of Proposition 5.6, Lemma 5.10, Proposition 5.12, Corollary 5.13, Proposition 5.15, Theorem 5.16, and Proposition 6.5. While these are new proofs, at least to the author’s knowledge, we emphasize that the underlying results themselves are well-known.

1.2. Structure of the article. This article is organized as follows. Section 2 addresses some of the relevant background on actions of complex algebraic groups, focusing largely on the structure of algebraic group orbits. It includes a number of examples, some of which are designed to give context and build intuition for later sections. Section 3 subsequently discusses a few critical topics in Lie theory. Firstly, in the interest of clarity and consistency in later sections, 3.1 fixes various objects that arise when one studies representations of a complex semisimple group (ex. a maximal torus, a Borel subgroup, weights, roots, etc.). Secondly, 3.2 and 3.3 review the basics of semisimple and nilpotent elements in a complex semisimple Lie algebra.

Section 4 specializes the previous sections to examine the adjoint orbits of a complex semisimple group. Adjoint orbits are defined in 4.1 and 4.2 then introduces regular adjoint orbits. Next, 4.3 presents some results relating Jordan decompositions to the study of adjoint orbits. Section 4.4 discusses adjoint orbits in the context of the adjoint quotient, concluding with some of Kostant’s foundational results (see Theorem 4.7). The topics
become more manifestly geometric in 4.5 which mentions the role of adjoint orbits in hyperkähler and holomorphic symplectic geometry.

Section 5 is devoted to semisimple adjoint orbits and their features. These orbits are introduced in 5.1 where it is also shown that semisimple orbits are exactly the closed orbits of the adjoint action (see Theorem 5.4). Section 5.2 develops a uniform description of a semisimple element’s stabilizer under the adjoint action of a complex semisimple group (see Proposition 5.6 and Corollary 5.7). The discussion becomes more esoteric in Sections 5.3 and 5.4. The former shows semisimple orbits to be explicitly diffeomorphic to cotangent bundles of partial flag varieties $G/P$ (see Proposition 5.12), which is consistent with results in hyperkähler geometry (see Remark 5.9). Section 5.4 reviews a procedure for compactifying semisimple orbits (see Theorem 5.16), and subsequently gives some context from the homological mirror symmetry program (see Remark 5.17).

Section 6 is exclusively concerned with nilpotent adjoint orbits and their properties. It begins with 6.1 in which nilpotent orbits are defined and then characterized in several equivalent ways. Also included is a proof that there are only finitely many nilpotent orbits of a given complex semisimple group (see Theorem 6.4). Section 6.2 studies the set of nilpotent orbits as a poset, partially ordered by the closure order. In particular, it recalls Gerstenhaber and Hesselink’s classical description of this poset in Lie type $A$ (see Example 6.7). Section 6.3 shows there to be a unique maximal element in the poset of nilpotent orbits (see Proposition 6.8), called the regular nilpotent orbit. We also recall Kostant’s construction of a standard representative for this orbit (see Proposition 6.10). Next, 6.4 introduces $O_{\text{min}}$, the minimal (non-zero) nilpotent orbit of a complex simple group. This leads to a discussion of nilpotent orbit projectivizations in 6.5 where $\mathbb{P}(O_{\text{min}})$ and its properties are discussed in detail. Some emphasis is placed on the role of $\mathbb{P}(O_{\text{min}})$ in quaternionic-Kähler geometry. Lastly, 6.6 outlines how nilpotent orbit closures can arise in geometric representation theory, and in the study of symplectic singularities and resolutions.

1.3. Acknowledgements. The author is grateful to Roger Bielawski, Steven Rayan, and Markus Röser for many fruitful discussions, and to the Institute of Differential Geometry at Leibniz Universität Hannover for its hospitality.

1.4. General conventions. While many of our conventions will be declared in Sections 2 and 3 the following are some things we can establish in advance.

- We will discuss several objects that, strictly speaking, make sense only when a base field has been specified (ex. vector spaces, Lie algebras, representations, algebraic varieties, etc.). Unless we indicate otherwise, we will always take this field to be $\mathbb{C}$.
- If $X$ is a set with an equivalence relation $\sim$, then $[x] \in X/\sim$ will denote the equivalence class of $x \in X$. The equivalence relations of interest to us will usually come from the (left) action of a group $G$ on a set $X$, in which $x_1 \sim x_2$ if and only if $x_2 = g \cdot x_1$ for some $g \in G$. In such cases, we will denote the quotient set $X/\sim$ by $X/G$.
- Many of the spaces we will consider can be viewed both as algebraic varieties with their Zariski topologies, and as manifolds with their analytic topologies. Accordingly, if one of our statements has topological content, the reader should by default understand the underlying topology to be the Zariski topology. Only when a
space does not have a clear algebraic variety structure (ex. a compact Lie group or an orbit thereof), or when manifold-theoretic terms are being used (ex. diffeomorphism, holomorphic, homotopy-equivalence, equivariant cohomology) should we be understood as referring to the analytic topology.

2. PRELIMINARIES ON ALGEBRAIC GROUP ACTIONS

In what follows, we review some pertinent concepts from the theory of group actions on algebraic varieties. This review is designed to serve two principal purposes: to clearly establish some of our major conventions, and to give motivation/context for what is to come. However, it is not intended to be a comprehensive overview of algebraic group actions. For this, we refer the reader to [36, Chapt. II–IV].

2.1. Definitions and examples. Let $G$ be a connected linear algebraic group with Lie algebra $\mathfrak{g}$ and adjoint representation $\text{Ad} : G \to \text{GL}(\mathfrak{g})$. By $G$-variety, we shall mean an algebraic variety $X$ equipped with an algebraic $G$-action, namely a variety morphism $G \times X \to X$, $(g, x) \mapsto g \cdot x$, satisfying the usual properties of a left $G$-action:

(i) $e \cdot x = x$ for all $x \in X$, where $e \in G$ is the identity element,
(ii) $(g_1 g_2) \cdot x = g_1 \cdot (g_2 \cdot x)$ for all $g_1, g_2 \in G$ and $x \in X$.

A morphism of $G$-varieties is then appropriately defined to be a $G$-equivariant morphism of algebraic varieties, ie. a variety morphism $\varphi : X \to Y$ satisfying $\varphi(g \cdot x) = g \cdot \varphi(x)$ for all $g \in G$ and $x \in X$. This induces the definition of a $G$-variety isomorphism, which is precisely a $G$-equivariant isomorphism of algebraic varieties.

The literature contains many examples of $G$-varieties and related ideas, some of which we mention below.

**Example 2.1.** Let $G = \text{GL}_n(\mathbb{C})$ act by left multiplication on the vector space of $n \times n$ matrices $\text{Mat}_{n \times n}(\mathbb{C})$, so that $g \cdot A = gA$, $g \in \text{GL}_n(\mathbb{C})$, $A \in \text{Mat}_{n \times n}(\mathbb{C})$. In this way, $\text{Mat}_{n \times n}(\mathbb{C})$ is a $\text{GL}_n(\mathbb{C})$-variety.

**Example 2.2.** Alternatively, one has the conjugation action of $\text{GL}_n(\mathbb{C})$ on $\text{Mat}_{n \times n}(\mathbb{C})$, ie. $g \cdot A = gA g^{-1}$, $g \in \text{GL}_n(\mathbb{C})$, $A \in \text{Mat}_{n \times n}(\mathbb{C})$. This, too, renders $\text{Mat}_{n \times n}(\mathbb{C})$ a $\text{GL}_n(\mathbb{C})$-variety.

**Example 2.3.** By a flag in $\mathbb{C}^n$, we shall mean a sequence

$$V_* = (\{0\} \subsetneq V_1 \subsetneq V_2 \subsetneq \cdots \subsetneq V_k \subsetneq \mathbb{C}^n)$$

of subspaces of $\mathbb{C}^n$. Now, suppose that $d_* = (d_1, d_2, \ldots, d_k)$ is a strictly increasing sequence of integers with $1 \leq d_i \leq n - 1$ for all $i = 1, \ldots, k$. We denote by $\text{Flag}(d_*, \mathbb{C}^n)$ the set of all flags in $\mathbb{C}^n$ whose constituent subspaces have dimensions $d_1, d_2, \ldots, d_k$, namely

$$\text{Flag}(d_*, \mathbb{C}^n) = \{V_* : \dim(V_i) = d_i, \ i = 1, \ldots, k\}.$$  

This is a smooth projective variety and it carries a $\text{GL}_n(\mathbb{C})$-variety structure in which $\text{GL}_n(\mathbb{C})$ acts via

$$g \cdot V_* = (\{0\} \subsetneq gV_1 \subsetneq gV_2 \subsetneq \cdots \subsetneq gV_k \subsetneq \mathbb{C}^n), \quad g \in \text{GL}_n(\mathbb{C}), \ V_* \in \text{Flag}(d_*, \mathbb{C}^n).$$

**Example 2.4.** Let $X$ be a $G$-variety and $H \subseteq G$ a closed subgroup. One can restrict the $G$-action to $H$ in the sense that $H \times X \to X$, $(h, x) \mapsto h \cdot x$, $h \in H, x \in X$ defines an $H$-variety structure on $X$.
Example 2.5. Let $X$ be a $G$-variety and $Y \subseteq X$ a locally closed subvariety. If $g \cdot y \in Y$ for all $g \in G$ and $y \in Y$, we will refer to $Y$ as being $G$-invariant (or simply invariant if the action is clear from context). In this case, the map $G \times Y \to Y, (g,y) \mapsto g \cdot y$, is a $G$-variety structure on $Y$.

Example 2.6. Let $X$ and $Y$ be $G$-varieties. The product $X \times Y$ then carries a canonical $G$-variety structure, defined by the “diagonal” $G$-action

$$g \cdot (x,y) = (g \cdot x, g \cdot y), \quad g \in G, \quad (x,y) \in X \times Y.$$ 

Example 2.7. Let $V$ be a $G$-representation, meaning for us that $V$ is a finite-dimensional vector space together with a morphism of algebraic groups $\rho : G \to \GL(V)$ (ex. $V = g$ and $\rho = \text{Ad}$). In this case, the map $G \times V \to V, (g,v) \mapsto \rho(g)(v)$, gives $V$ the structure of a $G$-variety. Note that Examples 2.8 and 2.10 feature $G$-varieties induced by representations.

Example 2.8. As a counterpart to the last example, one can use $G$-varieties to induce representations. To this end, let $X$ be a $G$-variety and for each $g \in G$ let $\phi_g : X \to X$ be the automorphism defined by $\phi_g(x) = g \cdot x$. Now suppose $H \subseteq G$ is a closed subgroup and $x \in X$ is a point satisfying $h \cdot x = x$ (ie. $\phi_h(x) = x$) for all $h \in H$. It follows that the differential of $\phi_h$ at $x$ is a vector space automorphism $d_x(\phi_h) : T_xX \to T_xX$ of the tangent space $T_xX$. Furthermore, one can verify that $H \to \GL(T_xX), h \mapsto d_x(\phi_h)$, is an $H$-representation.

Example 2.9. Let $\rho : G \to \GL(V)$ be a $G$-representation, and let $P(V) = (V \setminus \{0\})/\mathbb{C}^*$ denote the projectivization of $V$. The formula $g \cdot [v] = [\rho(g)(v)]$ gives a well-defined action of $G$ on $P(V)$, rendering the latter a $G$-variety.

Example 2.10. Let $X$ be an affine $G$-variety and $\mathbb{C}[X]$ the algebra of regular functions on $X$. This algebra carries a canonical action of $G$ by algebra automorphisms, in which $g \in G$ acts on $f \in \mathbb{C}[X]$ by $(g \cdot f)(x) := f(g^{-1} \cdot x), x \in X$.

Example 2.11. Let $H$ be a closed subgroup of $G$. The set of left $H$-cosets $X = G/H = \{gH : g \in G\}$ is naturally an algebraic variety. Furthermore, when $G$ acts by left multiplication, $G/H$ is a $G$-variety.

A few remarks are in order. Firstly, one may summarize Examples 2.7 and 2.9 together as the statement that a $G$-representation $V$ induces canonical $G$-variety structures on both $V$ and $P(V)$. We will always understand $V$ and $P(V)$ to be $G$-varieties in exactly this way when $V$ is a $G$-representation. Secondly, we shall always view a variety $G/H$ as carrying the left-multiplicative action of $G$.

2.2. Generalities on orbits. Let $X$ be a $G$-variety. One may associate to each point $x \in X$ the subset

$$\O_G(x) := \{g \cdot x : g \in G\},$$

called the $G$-orbit of $x$. Should the underlying group $G$ be clear from context, we will sometimes suppress it and write $\O(x)$ in place of $\O_G(x)$. Now, let us call $\emptyset \subseteq X$ a $G$-orbit

---

1Recall that a subset of $X$ is defined to be locally closed if it is expressible as the intersection of an open and a closed subset of $X$. Equivalently, a subset is locally closed if and only if the subset is open in its closure.
if \( \emptyset = \emptyset(x) \) for some \( x \in X \). In this case, \( \overline{\emptyset} \) shall denote the closure of \( \emptyset \) in \( X \). The orbit \( \emptyset \) is open in \( \overline{\emptyset} \) (ie. is locally closed), so that \( \emptyset \) inherits from \( X \) the structure of a subvariety. Furthermore, \( \emptyset \) is known to be a smooth subvariety of \( X \).

**Example 2.12.** Let \( \text{GL}_n(\mathbb{C}) \) act by left multiplication on \( \text{Mat}_{n \times n}(\mathbb{C}) \). If \( A, B \in \text{Mat}_{n \times n}(\mathbb{C}) \), then \( B = gA \) for some \( g \in \text{GL}_n(\mathbb{C}) \) if and only if \( A \) and \( B \) are equivalent under row operations, which holds if and only if their reduced echelon forms coincide. It follows that the \( \text{GL}_n(\mathbb{C}) \)-orbits are parametrized by the set of \( n \times n \) matrices in reduced echelon form. In particular, the orbit of matrices with reduced echelon form \( I_n \) is \( \emptyset(I_n) = \text{GL}_n(\mathbb{C}) \subseteq \text{Mat}_{n \times n}(\mathbb{C}) \). This orbit is open and dense.

**Example 2.13.** Let \( \text{GL}_n(\mathbb{C}) \) act by conjugation on \( \text{Mat}_{n \times n}(\mathbb{C}) \), so that the \( \text{GL}_n(\mathbb{C}) \)-orbits are precisely the conjugacy classes of matrices in \( \text{Mat}_{n \times n}(\mathbb{C}) \). These classes are indexed by the equivalence classes of \( n \times n \) matrices in Jordan canonical form, where two such matrices are equivalent if they agree up to a reordering of Jordan blocks along the diagonal. To build some algebro-geometric intuition for these orbits, we specialize to three cases.

- Suppose that \( A \in \text{Mat}_{n \times n}(\mathbb{C}) \) is diagonal with pairwise distinct eigenvalues \( \lambda_1, \ldots, \lambda_n \in \mathbb{C} \). If \( B \in \text{Mat}_{n \times n}(\mathbb{C}) \), then \( B \in \emptyset(A) \) if and only if the characteristic polynomial of \( B \) has the form

  \[
  \det(\lambda I_n - B) = (\lambda - \lambda_1)(\lambda - \lambda_2) \cdots (\lambda - \lambda_n).
  \]

  Equating corresponding coefficients of \( \lambda^k \) for each \( k \in \{0, 1, \ldots, n-1\} \), we obtain \( n \) polynomial equations in the entries of \( B \). From this, it follows that \( \emptyset(A) \) is a closed (hence affine) subvariety of \( \text{Mat}_{n \times n}(\mathbb{C}) \).

- Let \( N_1 \in \text{Mat}_{n \times n}(\mathbb{C}) \) be the matrix consisting of a single nilpotent Jordan block. If \( B \in \text{Mat}_{n \times n}(\mathbb{C}) \), then \( B \in \emptyset(N_1) \) if and only \( B \) has a minimal polynomial of \( \lambda^n \), ie.

  \[
  \emptyset(N_1) = \{ B \in \text{Mat}_{n \times n}(\mathbb{C}) : B^n = 0, B^{n-1} \neq 0 \}.
  \]

  The conditions \( B^n = 0 \) and \( B^{n-1} \neq 0 \) define closed and open subsets of \( \text{Mat}_{n \times n}(\mathbb{C}) \), respectively, and \( \emptyset(N_1) \) is the intersection of these subsets. We thus see explicitly that \( \emptyset(N_1) \) is locally closed. Also, one can show that \( \emptyset(N_1) = \{ B \in \text{Mat}_{n \times n}(\mathbb{C}) : B^n = 0 \} \), the locus of all nilpotent matrices.

- Let \( N_2 \in \text{Mat}_{n \times n}(\mathbb{C}) \) be a nilpotent matrix in Jordan canonical form having a single \( 2 \times 2 \) Jordan block and all remaining blocks of dimension \( 1 \times 1 \). To describe \( \emptyset(N_2) \), note that the Jordan canonical form of a nilpotent \( B \in \text{Mat}_{n \times n}(\mathbb{C}) \) has only \( 1 \times 1 \) and \( 2 \times 2 \) blocks if and only if \( B^2 = 0 \). To ensure the existence of exactly one \( 2 \times 2 \) block, one must impose the condition \( \text{rank}(B) = 1 \). Equivalently, one requires that \( B \neq 0 \) and that all \( 2 \times 2 \) minors of \( B \) vanish. It follows that

  \[
  \emptyset(N_2) = \{ B \in \text{Mat}_{n \times n}(\mathbb{C}) : B^2 = 0, \text{rank}(B) = 1 \}
  = \{ B \in \text{Mat}_{n \times n}(\mathbb{C}) : B^2 = 0, \text{every } 2 \times 2 \text{ minor of } B = 0, B \neq 0 \}.
  \]

  As with \( \emptyset(N_1) \), we explicitly see that \( \emptyset(N_2) \) is the intersection of a closed subset of \( \text{Mat}_{n \times n}(\mathbb{C}) \) (defined by \( B^2 = 0 \) and the vanishing of the \( 2 \times 2 \) minors) with an open subset (defined by \( B \neq 0 \)). Furthermore, it is not difficult to see that \( 0 \in \overline{\emptyset(N_2)} \), and that \( \emptyset(N_2) \cup \{0\} \) is the closed subset mentioned in the previous sentence. We conclude that \( \overline{\emptyset(N_2)} = \emptyset(N_2) \cup \{0\} \).
Example 2.14. Refer to Example 2.3 in which $GL_n(\mathbb{C})$ acts on $\text{Flag}(d^\bullet; \mathbb{C}^n)$. One can verify that this action is transitive, so that $\text{Flag}(d^\bullet; \mathbb{C}^n)$ is the unique $GL_n(\mathbb{C})$-orbit. However, let us restrict the $GL_n(\mathbb{C})$-action to the Borel subgroup $B$ of upper-triangular matrices. To describe the $B$-orbits, let $w \in S_n$ be a permutation and consider the point

$$V_w^w := ([0] \subsetneq V_1^w \subsetneq V_2^w \subsetneq \ldots \subsetneq V_k^w \subsetneq \mathbb{C}^n) \in \text{Flag}(d^\bullet; \mathbb{C}^n),$$

where $V_i^w := \text{span}(e_{w(1)}, e_{w(2)}, \ldots, e_{w(d_i)})$, $i \in \{1, 2, \ldots, k\}$. It turns out that $w \mapsto O_B(V_w^w)$ is a surjection from $S_n$ to the collection of $B$-orbits. Furthermore, $O_B(V_w^w)$ is isomorphic to an affine space and called a Schubert cell, alluding to the fact that the $B$-orbits constitute a cell decomposition of $\text{Flag}(d^\bullet; \mathbb{C}^n)$. The $B$-orbit closures are the well-studied Schubert varieties.

For further details in this direction, we refer the reader to [25, Chapt. 10].

2.3. Orbits as quotient varieties. Let $X$ be a $G$-variety and $\mathcal{O} \subseteq X$ an orbit. Since $\mathcal{O}$ is locally closed and $G$-invariant, it inherits from $X$ the structure of a $G$-variety (cf. Example 2.5). To better understand this structure, fix a point $x \in \mathcal{O}$ and consider its $G$-stabilizer

$$C_G(x) := \{g \in G : g \cdot x = x\}.$$

This is a closed subgroup of $G$ and one has a well-defined $G$-variety isomorphism

$$G/C_G(x) \xrightarrow{\sim} \mathcal{O}, \quad [g] \mapsto g \cdot x.$$

Note that (3) is just the Orbit-Stabilizer Theorem in an algebro-geometric context.

One can use (3) to yield a convenient description of the tangent space $T_x\mathcal{O}$. Indeed, since (3) sends the identity coset $[e] \in G/C_G(x)$ to $x$, it determines an isomorphism of tangent spaces,

$$T_{[e]}(G/C_G(x)) \xrightarrow{\sim} T_x\mathcal{O}.$$

Also, the differential of $G \to G/C_G(x)$ at $e \in G$ is surjective with kernel the Lie algebra of $C_G(x)$. Let us denote this Lie algebra by $\mathfrak{g}_G(x)$, so that we have $T_{[e]}(G/C_G(x)) \cong \mathfrak{g}/C_G(x)$ as vector spaces. The isomorphism (4) then takes the form

$$T_x\mathcal{O} \cong \mathfrak{g}/C_G(x).$$

It turns out that (5) is more than an isomorphism of vector spaces. To see this, note that $T_x\mathcal{O}$ is a $C_G(x)$-representation by virtue of $x$ being fixed by $C_G(x)$ (see Example 2.8). At the same time, $\mathfrak{g}$ carries the adjoint representation of $G$, and one can restrict this to a representation of $C_G(x)$. One notes that $\mathfrak{g}_G(x)$ is a $C_G(x)$-invariant subspace, making the quotient $\mathfrak{g}/C_G(x)$ a $C_G(x)$-representation. With this discussion in mind, one can verify that (5) is actually an isomorphism of $C_G(x)$-representations.

Example 2.15. Recall the action of $GL_n(\mathbb{C})$ on $\text{Flags}(d^\bullet; \mathbb{C}^n)$ from Example 2.3. Following the notation of Example 2.14, the $GL_n(\mathbb{C})$-stabilizer of the flag $V^*_x$ is

$$C_{GL_n(\mathbb{C})}(V^*_x) = \{(A_{ij}) \in GL_n(\mathbb{C}) : A_{ij} = 0 \text{ for all } r \in \{1, \ldots, k\}, i > d_r, j \in \{d_{r-1}, \ldots, d_r\}\}.$$

More simply, a matrix $A \in GL_n(\mathbb{C})$ is in $C_{GL_n(\mathbb{C})}(V^*_x)$ if and only if it is block upper-triangular with blocks of dimensions $d_1 \times d_1, (d_2 - d_1) \times (d_2 - d_1), \ldots, (d_k - d_{k-1}) \times (d_k - d_{k-1})$, $(n - d_k) \times (n - d_k)$ along the diagonal (read from top to bottom). Now, since the action of $GL_n(\mathbb{C})$ on $\text{Flags}(d^\bullet; \mathbb{C}^n)$ can be shown to be transitive, (3) gives an isomorphism

$$GL_n(\mathbb{C})/C_{GL_n(\mathbb{C})}(V^*_x) \cong \text{Flags}(d^\bullet; \mathbb{C}^n).$$
Example 2.16. Recall Example 2.13 and let $A, N_1 \in \text{Mat}_{n \times n}(\mathbb{C})$ be as introduced there. One can verify that $C_{GL_n(\mathbb{C})}(A)$ is the maximal torus of diagonal matrices in $GL_n(\mathbb{C})$, while $C_{GL_n(\mathbb{C})}(N_1)$ can be seen to have the following description:

$$C_{GL_n(\mathbb{C})}(N_1) = \{ (B_{ij}) \in GL_n(\mathbb{C}) : B_{ij} = 0 \text{ for } i > j, B_{ij} = B_{(i+1)(j+1)} \text{ for } 1 \leq i \leq j \leq n - 1 \}.$$ 

In other words, a matrix $B \in GL_n(\mathbb{C})$ is in $C_{GL_n(\mathbb{C})}(N_1)$ if and only if $B$ is upper-triangular and any two entries of $B$ lying on the same diagonal must be equal. Now, let $U \subseteq C_{GL_n(\mathbb{C})}(N_1)$ be the unipotent subgroup of matrices having only 1 along the main diagonal. This subgroup is complementary to the centre $Z(GL_n(\mathbb{C}))$, and one has an internal direct product decomposition $C_{GL_n(\mathbb{C})}(N_1) = Z(GL_n(\mathbb{C})) \times U$.

2.4. The closure order. The set of orbits in a $G$-variety $X$ turns out to have a canonical partial order, based fundamentally on the following proposition.

Proposition 2.17. If $\emptyset \subseteq X$ is a $G$-orbit, then $\overline{O}$ is a union of $\emptyset$ and orbits having dimensions strictly less than $\text{dim}(\emptyset)$.

Proof. Choose $x \in \emptyset$ and note that $\emptyset$ is the image of the morphism $G \to X, g \mapsto g \cdot x$. Since $G$ is irreducible, so too is the image $\emptyset$. It follows that $\overline{\emptyset}$ is also irreducible. Appealing to the fact that $\emptyset$ is locally closed (i.e. open in $\overline{\emptyset}$), we see that $\overline{\emptyset} \setminus \emptyset$ is a closed subvariety of $\overline{\emptyset}$, each of whose irreducible components then necessarily has dimension strictly less than $\text{dim}(\overline{\emptyset}) = \text{dim}(\emptyset)$ (see [36 Sect. 3.2]). Of course, as $\overline{\emptyset} \setminus \emptyset$ is $G$-invariant, it is a union of $G$-orbits. Each of these orbits is also irreducible and therefore has dimension at most that of an irreducible component of $\overline{\emptyset} \setminus \emptyset$ to which it belongs. Our previous discussion implies that the dimension of such an orbit is strictly less than $\text{dim}(\emptyset)$. \hfill $\square$

Proposition 2 implies that each $G$-orbit $\emptyset$ is the unique orbit in $\overline{\emptyset}$ having dimension $\text{dim}(\emptyset)$. With this in mind, suppose that $\emptyset_1, \emptyset_2 \subseteq X$ are $G$-orbits satisfying $\emptyset_1 \subseteq \overline{\emptyset_2}$ and $\emptyset_2 \subseteq \overline{\emptyset_1}$. These inclusions show $\emptyset_1$ and $\emptyset_2$ to have the same dimension. Since both orbits lie in $\overline{\emptyset_1}$, it follows that $\emptyset_1 = \emptyset_2$ must hold. It is thus not difficult to see that

$$\emptyset_1 \leq \emptyset_2 \iff \emptyset_1 \subseteq \overline{\emptyset_2}$$

deﬁnes a partial order on the set of $G$-orbits in $X$, which we shall call the closure order.

Example 2.18. Recall the setup of Example 2.13 in which $GL_n(\mathbb{C})$ acts by conjugation on $\text{Mat}_{n \times n}(\mathbb{C})$ and $A, N_1, N_2 \in \text{Mat}_{n \times n}(\mathbb{C})$ are three fixed matrices. Having shown $\emptyset(A)$ to be closed in $\text{Mat}_{n \times n}(\mathbb{C})$, we see that $\emptyset(A)$ is a minimal element in the closure order. Secondly, remembering that $\overline{\emptyset(N_1)}$ is the locus of all nilpotent $n \times n$ matrices, the $G$-orbits in $\overline{\emptyset(N_1)}$ are the conjugacy classes of nilpotent matrices. These conjugacy classes are therefore precisely the orbits $\emptyset \subseteq \text{Mat}_{n \times n}(\mathbb{C})$ satisfying $\emptyset \leq \emptyset(N_1)$. Finally, having seen in Example 2.13 that $\overline{\emptyset(N_2)} = \emptyset(N_1) \cup \{0\}$, we conclude that $\emptyset$ and $\emptyset(N_2)$ are the unique orbits $\emptyset$ satisfying $\emptyset \leq \emptyset(N_2)$.

Example 2.19. Refer to Examples 2.3 and 2.14, where $GL_n(\mathbb{C})$ and its subgroup $B$ act on $\text{Flag}(d_*; \mathbb{C}^n)$. We will assume that $d_* = (1, 2, \ldots, n - 1)$, in which case $w \mapsto \emptyset_B(V^w_w)$ is a bijection from $S_n$ to the set of $B$-orbits. The latter set has the closure order, and there is a unique partial order on $S_n$ for which our bijection is a poset isomorphism. One thereby obtains the well-studied Bruhat order on $S_n$, which we now describe. Given $i \in \{1, \ldots, n-
1 \rangle$, let $s_i \in S_n$ be the transposition interchanging $i$ and $i + 1$. The $n - 1$ transpositions $s_i$ generate $S_n$, so that each $w \in S_n$ has an expression $w = s_{i_1} s_{i_2} \cdots s_{i_k}$. One calls such an expression reduced if its length $k$ is minimal. Now given $v, w \in S_n$, the Bruhat order is defined as follows: $v \leq w$ if whenever $w = s_{i_1} s_{i_2} \cdots s_{i_k}$ is a reduced expression for $w$, it is possible to delete some of the $s_{i_j}$ so that the resulting expression is a reduced expression for $v$.

3. PRELIMINARIES ON LIE THEORY

The following is a brief review of Lie-theoretic topics central to this article, with a strong emphasis on the structure of semisimple algebraic groups and their Lie algebras. Like the previous section, this review is more concerned with establishing clear conventions than being comprehensive. References for the relevant Lie theory include [36, Chapt. III–VIII] and [57, Chapt. 20–29].

3.1. The basic objects. In what follows, we introduce several Lie-theoretic objects to be understood as fixed for the rest of this article. To begin, let $G$ be a connected, simply-connected semisimple linear algebraic group having Lie algebra $\mathfrak{g}$ and exponential map $\exp : \mathfrak{g} \to G$. Let

$$\text{Ad} : G \to \text{GL}(\mathfrak{g}), \quad g \mapsto \text{Ad}_g, \quad g \in G$$

and

$$\text{ad} : \mathfrak{g} \to \text{gl}(\mathfrak{g}), \quad x \mapsto \text{ad}_x, \quad x \in \mathfrak{g}$$

denote the adjoint representations of $G$ and $\mathfrak{g}$, respectively. Recall that $\text{Ad}_g$ is a Lie algebra automorphism of $\mathfrak{g}$ for all $g \in G$, a fact we will use repeatedly. Note also that $\text{ad}_x(y) = [x, y]$ for all $x, y \in \mathfrak{g}$, from which it follows that the kernel of $\text{ad}$ is the centre of $\mathfrak{g}$. This centre is trivial by virtue of the fact that $\mathfrak{g}$ is semisimple. In other words, $\text{ad}$ is injective.

Now, suppose that $T \subseteq B \subseteq G$, with $T$ a maximal torus of $G$ and $B$ a Borel subgroup of $G$. One then has inclusions $t \subseteq \mathfrak{b} \subseteq \mathfrak{g}$, where $t$ and $\mathfrak{b}$ are the Lie algebras of $T$ and $B$, respectively. Let $X^*(T)$ be the additive group of weights (i.e. algebraic group morphisms $T \to \mathbb{C}^*$), with the sum of $\lambda_1, \lambda_2 \in X^*(T)$ defined by $(\lambda_1 + \lambda_2)(t) = \lambda_1(t) \lambda_2(t)$ for all $t \in T$. The map sending $\lambda \in X^*(T)$ to its differential at the identity $e \in T$ includes $X^*(T)$ into $t^*$ as an additive subgroup. Where appropriate, we will use this inclusion to regard a weight as belonging to $t^*$.

Given a weight $\alpha \in X^*(T)$, let us set

$$\mathfrak{g}_\alpha := \{x \in \mathfrak{g} : \text{Ad}_t(x) = \alpha(t)x \text{ for all } t \in T\}.$$ 

If we regard $\alpha$ as belonging to $t^*$, then $\mathfrak{g}_\alpha$ admits the following alternative description:

$$\mathfrak{g}_\alpha = \{x \in \mathfrak{g} : \text{ad}_h(x) = \alpha(h)x \text{ for all } h \in t\}.$$ 

One knows that $\mathfrak{g}_0 = t$, while any non-zero weight $\alpha$ satisfying $\mathfrak{g}_\alpha \neq \{0\}$ is called a root. In this case, $\mathfrak{g}_\alpha$ is one-dimensional and called a root space. Furthermore, letting $\Delta \subseteq X^*(T)$ denote the set of roots, we have the following decomposition of $\mathfrak{g}$:

$$(7) \quad \mathfrak{g} = t \oplus \bigoplus_{\alpha \in \Delta} \mathfrak{g}_\alpha.$$ 

One can check that $[\mathfrak{g}_\alpha, \mathfrak{g}_\beta] \subseteq \mathfrak{g}_{\alpha + \beta}$ for all $\alpha, \beta \in \Delta$. In particular, if $\alpha + \beta$ is neither zero nor a root, then $[\mathfrak{g}_\alpha, \mathfrak{g}_\beta] = \{0\}$. 

Our choice of $B$ gives rise to several distinguished subsets of $\Delta$. The positive roots $\Delta_+$ are those $\alpha \in \Delta$ for which $g_\alpha \subseteq b$, so that

$$b = t \oplus \bigoplus_{\alpha \in \Delta_+} g_\alpha.$$ 

The negative roots $\Delta_- \subseteq \Delta$ are defined by negating the positive roots, i.e. $\Delta_- := -\Delta_+$. We then have a disjoint union $\Delta = \Delta_+ \cup \Delta_-$. Finally, the simple roots $\Pi \subseteq \Delta$ are positive roots with the property that every $\beta \in \Delta$ can be written as

$$\beta = \sum_{\alpha \in \Pi} c_\alpha \alpha$$

for unique coefficients $c_\alpha \in \mathbb{Z}$. These coefficients are either all non-negative (in which case $\beta \in \Delta_+$) or all non-positive (in which case $\beta \in \Delta_-$). Furthermore, the simple roots are known to form a basis of $t^*$.

It will be beneficial to note that the weight lattice carries a particular partial order, defined in terms of the simple roots. Given $\beta, \gamma \in X^*(T)$, one has

$$\beta \leq \gamma \iff \gamma - \beta = \sum_{\alpha \in \Pi} c_\alpha \alpha$$

for some strictly non-negative integers $c_\alpha \in \mathbb{Z}$.

The Lie algebra $g$ carries a distinguished symmetric bilinear form $\langle \cdot, \cdot \rangle : g \otimes g \to \mathbb{C}$, called the Killing form and defined by

$$\langle x, y \rangle := \text{tr}(\text{ad}_x \circ \text{ad}_y), \quad x, y \in g.$$ 

This form is $G$-invariant in the sense that $\langle \text{Ad}_g(x), \text{Ad}_g(y) \rangle = \langle x, y \rangle$ for all $g \in G$ and $x, y \in g$. Furthermore, the Killing form is non-degenerate both on $g$ and when restricted to a bilinear form on $t$. This non-degeneracy gives rise to vector space isomorphisms $g \cong g^*$ and $t \cong t^*$, under which the Killing form corresponds to bilinear forms on $g^*$ and $t^*$, respectively. In an abuse of notation, we will also use $\langle \cdot, \cdot \rangle$ to denote these forms. Each simple root $\alpha \in \Pi$ then determines a simple coroot $h_\alpha \in t$, defined by the following property:

$$\phi(h_\alpha) = 2\frac{\langle \alpha, \phi \rangle}{\langle \alpha, \alpha \rangle}$$

for all $\phi \in t^*$. One can check that $h_\alpha \in [g_\alpha, g_{-\alpha}]$ and that the simple coroots form a basis of $t$.

Now let $W := N_G(T)/T$ be the Weyl group and $s_\alpha \in W$ the reflection associated to $\alpha \in \Delta$, so that $W$ is generated by the simple reflections $s_\alpha, \alpha \in \Pi$. Note that $W$ acts on $t$ by $w \cdot x = \text{Ad}_g(x), w \in W, x \in t$, where $g \in N_G(T)$ is any representative of $w$. There is an induced action on $t^*$ defined by

$$(w \cdot \phi)(x) = \phi(w^{-1} \cdot x), \quad w \in W, \phi \in t^*, \ x \in t,$$

under which the reflections act as follows:

$$s_\alpha \cdot \phi = \phi - 2\frac{\langle \alpha, \phi \rangle}{\langle \alpha, \alpha \rangle} \alpha, \quad \alpha \in \Delta, \ \phi \in t^*.$$ 

It is known that $X^*(T)$ and $\Delta$ are invariant under this $W$-action.
Now recall that a closed subgroup \( P \subseteq G \) is called \textit{parabolic} if \( P \) contains a conjugate of \( B \). If \( P \) contains \( B \) itself, one calls it a \textit{standard parabolic} subgroup. To construct such a subgroup, consider a subset \( S \subseteq \Pi \) and let \( \Delta_S \) (resp. \( \Delta_S^+ \), \( \Delta_S^- \)) denote the collection of roots (resp. positive roots, negative roots) expressible as \( \mathbb{Z} \)-linear combinations of the elements of \( S \). It follows that

\[
\begin{aligned}
P_S := b \oplus \bigoplus_{\alpha \in \Delta_S^-} g_{\alpha}
\end{aligned}
\]

is a Lie subalgebra of \( g \), and we shall let \( P_S \subseteq G \) denote the corresponding closed connected subgroup of \( G \). Note that \( P_S \) contains \( B \), by construction. Moreover, it turns out that \( S \mapsto P_S \) defines a bijective correspondence between the subsets of \( \Pi \) and the standard parabolic subgroups of \( G \). The inverse associates to a standard parabolic subgroup \( P \) the subset \( \Pi_P := \{ \alpha \in \Pi : g_{-\alpha} \subseteq p \} \), where \( p \) is the Lie algebra of \( P \).

We will later benefit from recalling a particular Levi decomposition of a standard parabolic subgroup \( P_S \) (cf. [36, Sect. 30.2]). One has

\[
\begin{aligned}
P_S = U_S \rtimes L_S,
\end{aligned}
\]

where \( U_S \) is the unipotent radical of \( P_S \) and \( L_S \) is a (reductive) Levi factor having Lie algebra

\[
\begin{aligned}
L_S := t \oplus \bigoplus_{\alpha \in \Delta_S} g_{\alpha} = \left( \bigoplus_{\alpha \in \Delta_S^-} g_{\alpha} \right) \oplus t \oplus \left( \bigoplus_{\alpha \in \Delta_S^+} g_{\alpha} \right).
\end{aligned}
\]

The Lie algebra of \( U_S \) is

\[
\begin{aligned}
u_S := \bigoplus_{\alpha \in \Delta_+ \setminus \Delta_S} g_{\alpha}.
\end{aligned}
\]

We now specialize some of the above Lie-theoretic generalities to the case of \( G = \text{SL}_n(\mathbb{C}) \), a recurring example in this article.

\textbf{Example 3.1.} Let \( G = \text{SL}_n(\mathbb{C}) \), whose Lie algebra is \( g = \text{sl}_n(\mathbb{C}) = \{ x \in \text{gl}_n(\mathbb{C}) : \text{tr}(x) = 0 \} \) with Lie bracket the commutator of matrices. The adjoint representations are given by

\[
\begin{aligned}
\text{Ad}_g(x) = gxg^{-1}, \quad \text{ad}_x(y) = [x, y] = xy - yx
\end{aligned}
\]

for all \( g \in \text{SL}_n(\mathbb{C}) \) and \( x, y \in \text{sl}_n(\mathbb{C}) \). Also, the Killing form \( \langle \cdot, \cdot \rangle \) is given by

\[
\begin{aligned}
\langle x, y \rangle = 2n \text{tr}(xy), \quad x, y \in \text{sl}_n(\mathbb{C}).
\end{aligned}
\]

One may take \( T \) and \( B \) to be the subgroups of diagonal and upper-triangular matrices in \( \text{SL}_n(\mathbb{C}) \), respectively. It follows that \( t \) and \( b \) are the Lie subalgebras of diagonal and upper-triangular matrices in \( \text{sl}_n(\mathbb{C}) \), respectively. Now, for each \( i \in \{ 1, \ldots, n \} \), let \( t_i \in X^*(T) \) be the weight defined by

\[
\begin{aligned}
t_i : T \to \mathbb{C}^*, \quad \begin{bmatrix} a_1 & 0 & \ldots & 0 \\ 0 & a_2 & \ldots & 0 \\ \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \ldots & a_n \end{bmatrix} \mapsto a_i.
\end{aligned}
\]
We then have $\Delta = \{t_i - t_j : 1 \leq i, j \leq n, i \neq j\}$, $\Delta_+ = \{t_i - t_j : 1 \leq i < j \leq n\}$, $\Delta_- = \{t_i - t_j : 1 \leq j < i \leq n\}$, and $\Pi = \{t_i - t_{i+1} : 1 \leq i \leq n - 1\}$. If $\alpha = t_i - t_j \in \Delta$, then $\mathfrak{sl}_n(\mathbb{C})_\alpha = \text{span}_{\mathbb{C}}(E_{ij})$ where $E_{ij} \in \mathfrak{sl}_n(\mathbb{C})$ has an entry of 1 in position $(i, j)$ and 0 elsewhere.

Recall that the Weyl group identifies with $S_n$ in such a way that $w \in S_n$ acts on $h \in \mathfrak{t}$ by permuting entries along the diagonal.

3.2. Semisimple and nilpotent elements. It will be prudent to recall some of the fundamentals concerning semisimple and nilpotent elements in $\mathfrak{g}$. We begin with the official, Lie-theoretic definitions of these terms.

**Definition 3.2.** We call a point $x \in \mathfrak{g}$ *semisimple* (resp. *nilpotent*) if $\text{ad}_x : \mathfrak{g} \to \mathfrak{g}$ is semisimple (resp. nilpotent) as a vector space endomorphism.

At first glance, there might appear to be other legitimate definitions. Suppose, for instance, that $\mathfrak{g}$ is explicitly presented as a subalgebra of $\mathfrak{gl}_n(\mathbb{C})$ for some $n$. Elements of $\mathfrak{g}$ are then $n \times n$ matrices, and one has the usual notions of "semisimple" and "nilpotent" for square matrices. Fortunately, these turn out to coincide with Definition 3.2 (see [57] Cor. 20.4.3]).

**Theorem 3.3.** If $\mathfrak{g}$ is a subalgebra of $\mathfrak{gl}_n(\mathbb{C})$, then $x \in \mathfrak{g}$ is semisimple (resp. nilpotent) in the sense of Definition 3.2 if and only if $x$ is semisimple (resp. nilpotent) as a matrix.

**Example 3.4.** Suppose that $G = \text{SL}_2(\mathbb{C})$, whose Lie algebra $\mathfrak{g} = \mathfrak{sl}_2(\mathbb{C})$ has the usual generators

\begin{equation}
(16) \quad X = \begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}, \quad H = \begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \quad Y = \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix}.
\end{equation}

By Theorem 3.3, it is immediate that $H$ is a semisimple element of $\mathfrak{sl}_2(\mathbb{C})$, while $X$ and $Y$ are nilpotent elements. The algebra $\mathfrak{sl}_2(\mathbb{C})$ and triple of elements $(X, H, Y)$ will play a substantial role in 3.3.

The relationship between semisimple (resp. nilpotent) elements of $\mathfrak{g}$ and semisimple (resp. nilpotent) matrices extends beyond Theorem 3.3. For instance, recall that if an $n \times n$ matrix is both semisimple and nilpotent, it is necessarily zero. At the same time, if $x \in \mathfrak{g}$ is both semisimple and nilpotent, so too is the endomorphism $\text{ad}_x : \mathfrak{g} \to \mathfrak{g}$. It follows that $\text{ad}_x = 0$, and the injectivity of $\text{ad} : \mathfrak{g} \to \mathfrak{gl}(\mathfrak{g})$ implies $x = 0$. For a second comparison, note that an $n \times n$ matrix is semisimple (resp. nilpotent) if and only if it is conjugate to a diagonal (resp. strictly upper-triangular) matrix. Dually, $x \in \mathfrak{g}$ is semisimple (resp. nilpotent) if and only if there exists $g \in G$ satisfying $\text{Ad}_g(x) \in \mathfrak{t}$ (resp. $\text{Ad}_g(x) \in \bigoplus_{\alpha \in \Delta} \mathfrak{g}_\alpha$).

Thirdly, one knows that every $n \times n$ matrix $A$ gives rise to unique $n \times n$ matrices $S$ and $N$ such that $S$ is semisimple, $N$ is nilpotent, $A = S + N$, and $SN = NS = 0$. The analogous fact is that for every $x \in \mathfrak{g}$, there exist unique elements $x_s, x_n \in \mathfrak{g}$ for which $x_s$ is semisimple, $x_n$ is nilpotent, $x = x_s + x_n$, and $[x_s, x_n] = 0$. The expression $x = x_s + x_n$ is called the *Jordan decomposition* of $x$, while $x_s$ and $x_n$ are called the semisimple and nilpotent parts of $x$, respectively.

Let us turn to a more geometric discussion. Denote by $\mathfrak{g}_{ss}$ and $\mathfrak{N}$ the subsets of semisimple and nilpotent elements of $\mathfrak{g}$, respectively. The latter is called the *nilpotent cone*, in reference to the fact that $\mathcal{N}$ is invariant under the dilation action of $\mathbb{C}^*$ on $\mathfrak{g}$. In the interest of
preparing for later sections of this article, let us mention a few preliminary facts concerning $\mathfrak{g}_{ss}$ and $\mathcal{N}$. Firstly, since the semisimple endomorphisms are open and dense in $\mathfrak{gl}(\mathfrak{g})$, it follows that $\mathfrak{g}_{ss}$ is an open dense subvariety of $\mathfrak{g}$. One analogously sees that $\mathcal{N}$ is a closed subvariety of $\mathfrak{g}$. Secondly, noting that $\text{Ad}_g$ is a Lie algebra automorphism for each $g \in G$, we conclude that $x \in \mathfrak{g}$ is semisimple (resp. nilpotent) if and only if $\text{Ad}_g(x)$ is semisimple (resp. nilpotent). This is equivalent to the observation that both $\mathfrak{g}_{ss}$ and $\mathcal{N}$ are invariant under the adjoint representation.

**Example 3.5.** Let $G = \text{SL}_2(\mathbb{C})$. By Theorem 3.3, $A \in \mathfrak{sl}_2(\mathbb{C})$ is nilpotent if and only if it is nilpotent as a matrix. Equivalently, the characteristic polynomial $\det(\lambda I_2 - A)$ is $\lambda^2$, which is the case if and only if $\det(A) = 0$ (the condition $\text{tr}(A) = 0$ being automatic). In other words, we have

$$\mathcal{N} = \left\{ \begin{bmatrix} x & y \\ z & -x \end{bmatrix} \in \mathfrak{sl}_2(\mathbb{C}) : x^2 + yz = 0 \right\}.$$ 

3.3. **The Jacobson-Morozov Theorem and $\mathfrak{sl}_2(\mathbb{C})$-triples.** Let $(X, H, Y)$ be the triple of matrices in $\mathfrak{sl}_2(\mathbb{C})$ from Example 3.4. These matrices form a $\mathbb{C}$-basis of $\mathfrak{sl}_2(\mathbb{C})$ and satisfy the following bracket relations:

$$[X, Y] = H, \quad [H, X] = 2X, \quad [H, Y] = -2Y. \quad (17)$$

More generally, one calls a triple $(x, h, y)$ of points in $\mathfrak{g}$ an $\mathfrak{sl}_2(\mathbb{C})$-triple if (17) holds in $\mathfrak{g}$ when $X$, $H$, and $Y$ are replaced with $x$, $h$, and $y$, respectively. Such triples are in bijective correspondence with the Lie algebra morphisms $\phi : \mathfrak{sl}_2(\mathbb{C}) \to \mathfrak{g}$, where $\phi \in \text{Hom}(\mathfrak{sl}_2(\mathbb{C}), \mathfrak{g})$ identifies with $(\phi(X), \phi(H), \phi(Y))$. Since any $\phi \in \text{Hom}(\mathfrak{sl}_2(\mathbb{C}), \mathfrak{g})$ is either zero or injective (a consequence of $\mathfrak{sl}_2(\mathbb{C})$ having no non-trivial ideals), there are exactly two possibilities for an $\mathfrak{sl}_2(\mathbb{C})$-triple $(x, h, y)$. Either $x = h = y = 0$ or $\text{span}_\mathbb{C}(x, h, y)$ is a subalgebra of $\mathfrak{g}$ isomorphic to $\mathfrak{sl}_2(\mathbb{C})$.

**Example 3.6.** Let $\alpha \in \Pi$ be a simple root and $h_\alpha \in [\mathfrak{g}_\alpha, \mathfrak{g}_{-\alpha}]$ the corresponding simple coroot (as defined in 3.1). If $e_\alpha \in \mathfrak{g}_\alpha$ and $e_{-\alpha} \in \mathfrak{g}_{-\alpha}$ are chosen so that $h_\alpha = [e_\alpha, e_{-\alpha}]$, then one can show $(e_\alpha, h_\alpha, e_{-\alpha})$ to be an $\mathfrak{sl}_2(\mathbb{C})$-triple.

**Example 3.7.** In the interest of preparing for discussions to come (particularly 6.3), we now consider a more complicated example (cf. [42] Lemma 5.2). To this end, since $\Pi$ is a basis of $t^*$, we may define $\{e_\alpha\}_{\alpha \in \Pi}$ to be the basis of $t$ satisfying

$$\alpha(e_\beta) = \begin{cases} 2 & \text{if } \alpha = \beta \\ 0 & \text{if } \alpha \neq \beta \end{cases} \quad (18)$$

for all $\alpha, \beta \in \Pi$. Now consider the semisimple element

$$h := \sum_{\alpha \in \Pi} e_\alpha \in t. \quad (19)$$

Noting that $\{h_\alpha\}_{\alpha \in \Pi}$ is a basis of $t$ (see 3.1), there exist unique coefficients $c_\alpha \in \mathbb{C}, \alpha \in \Pi$, such that

$$h = \sum_{\alpha \in \Pi} c_\alpha h_\alpha.$$
We now define \( \xi, \eta \in g \) by

\[
\xi := \sum_{\alpha \in \Pi} e_{\alpha}
\]

and

\[
\eta := \sum_{\alpha \in \Pi} c_{\alpha} e_{-\alpha},
\]

respectively, where for each \( \alpha \in \Pi \), \( e_{\alpha} \in g_{\alpha} \) and \( e_{-\alpha} \in g_{-\alpha} \) are chosen such that \( h_{\alpha} = [e_{\alpha}, e_{-\alpha}] \) (as in Example 3.6). Furthermore, we claim that \((\xi, h, \eta)\) is an \( sl_{2}(\mathbb{C}) \)-triple. To see this, first note that

\[
[\xi, \eta] = \sum_{\alpha, \beta \in \Pi} c_{\beta} [e_{\alpha}, e_{-\beta}].
\]

If \( \alpha, \beta \in \Pi \) are distinct, then the discussion of simple roots in 3.1 implies that \( \alpha - \beta \) cannot be a root. Since \( \alpha - \beta \) is also non-zero in this case, \([g_{\alpha}, g_{-\beta}] = \{0\}\) (see 3.1). In particular, \([e_{\alpha}, e_{-\beta}] = 0\) when \( \alpha \) and \( \beta \) are distinct. At the same time, we know that \([e_{\alpha}, e_{-\alpha}] = h_{\alpha}\) for all \( \alpha \in \Pi \). Hence (20) can be written as

\[
[\xi, \eta] = \sum_{\alpha \in \Pi} c_{\alpha} h_{\alpha} = h.
\]

Now computing \([h, \xi]\), we have

\[
[h, \xi] = \sum_{\alpha \in \Pi} [h, e_{\alpha}] = \sum_{\alpha \in \Pi} \alpha(h) e_{\alpha}.
\]

The description (19) of \( h \) implies that \( \alpha(h) = 2 \) for all \( \alpha \in \Pi \), so that

\[
[h, \xi] = \sum_{\alpha \in \Pi} 2 e_{\alpha} = 2 \xi.
\]

The verification of \([h, \eta] = -2\eta\) is similar, since \( -\alpha(h) = -2 \) for all \( \alpha \in \Pi \). It follows that \((\xi, h, \eta)\) is indeed an \( sl_{2}(\mathbb{C}) \)-triple.

We will benefit from understanding \( sl_{2}(\mathbb{C}) \)-triples in the context of the Jacobson-Morozov Theorem, a crucial result that will feature prominently in 4.3. To motivate this theorem, suppose that \((x, h, y)\) is the \( sl_{2}(\mathbb{C}) \)-triple corresponding to a non-zero (i.e. injective) \( \phi \in \text{Hom}(sl_{2}(\mathbb{C}), g) \). It follows that \( \phi \) defines an isomorphism with its image \( \text{span}_{\mathbb{C}}\{x, h, y\} \), so that \( \phi \) sends nilpotent elements of \( sl_{2}(\mathbb{C}) \) to nilpotent elements of \( \text{span}_{\mathbb{C}}\{x, h, y\} \). In particular, \( x = \phi(X) \) is nilpotent in \( \text{span}_{\mathbb{C}}\{x, h, y\} \). If one chooses a Lie algebra embedding \( g \subseteq gl_{n}(\mathbb{C}) \) then \( \text{span}_{\mathbb{C}}\{x, h, y\} \) becomes a subalgebra of \( gl_{n}(\mathbb{C}) \) and Theorem 3.3 implies that \( x \) is nilpotent matrix. By applying Theorem 3.3 again, this time to the subalgebra \( g \subseteq gl_{n}(\mathbb{C}) \), we see that \( x \) is nilpotent in \( g \). This is clearly also true when \( \phi = 0 \) (in which case \( x = 0 \)), so we have shown \( x \in g \) to be nilpotent whenever it appears as the first element in an \( sl_{2}(\mathbb{C}) \)-triple. For a converse, one has the Jacobson-Morozov Theorem.

**Theorem 3.8 (The Jacobson-Morozov Theorem; cf. [16, Thm. 3.7.1]).** If \( x \in g \) is nilpotent, then there exist \( h, y \in g \) such that \((x, h, y)\) is an \( sl_{2}(\mathbb{C}) \)-triple.

\(^2\) Since \( g \) is semisimple, such an embedding always exists. For instance, one may identify \( g \) with its image under the (injective) adjoint representation \( \text{ad} : g \to gl(g) \cong gl_{n}(\mathbb{C}), n = \dim(g) \).
4. General Adjoint Orbits

Equipped with Section 3, we can apply parts of Section 2 to study a distinguished class of algebraic group orbits – adjoint orbits. Our overarching objective is to give the background and context necessary for the more specialized discussions of semisimple and nilpotent adjoint orbits (Sections 5 and 6 respectively). Nevertheless, we will see that general adjoint orbits are interesting objects of study in Lie theory and geometry (see 4.5 for example).

4.1. Definitions and conventions. Following the framework of Example 2.7, the adjoint representation \( \text{Ad} : G \to \text{GL}(\mathfrak{g}) \) induces a \( G \)-variety structure on \( \mathfrak{g} \). One calls the resulting action the adjoint action and its orbits adjoint orbits.

Example 4.1. Let \( G = \text{SL}_n(\mathbb{C}) \). Referring to (14), we see that the adjoint orbits of \( \text{SL}_n(\mathbb{C}) \) are precisely the conjugacy classes of the traceless \( n \times n \) matrices. Note that the term “conjugacy class” is unambiguous, since two \( n \times n \) matrices are conjugate under \( \text{SL}_n(\mathbb{C}) \) if and only if they are conjugate under \( \text{GL}_n(\mathbb{C}) \). With this point in mind, Example 2.13 describes several adjoint \( \text{SL}_n(\mathbb{C}) \)-orbits.

Now, recall the discussion of stabilizers from 2.3. Given \( x \in \mathfrak{g} \), we shall always understand \( C_G(x) \) as referring to the \( G \)-stabilizer of \( x \) under the adjoint action, i.e.

\[
C_G(x) := \{ g \in G : \text{Ad}_g(x) = x \}, \quad x \in \mathfrak{g}.
\]

The following fact about its Lie algebra, \( C_{\mathfrak{g}}(x) \subseteq \mathfrak{g} \), will be used repeatedly and (in the interest of parsimony) without explicit indication that it is being used.

Lemma 4.2 (cf. [38, Sect. 2.2]). If \( x \in \mathfrak{g} \), then \( C_{\mathfrak{g}}(x) = \{ y \in \mathfrak{g} : [x, y] = 0 \} \).

4.2. Dimension and regularity. In the interest of later sections, we now take a moment to discuss the dimensions of adjoint orbits. One might begin with the observation that each adjoint orbit can have dimension at most \( \dim(G) \). However, this dimension bound turns out to be highly sub-optimal. To improve it, we note that \( \dim(C_G(x)) \geq \text{rank}(G) \) for all \( x \in \mathfrak{g} \) (see [57, Sect. 19.7, Sect. 29.3]). It follows that

\[
\dim(\mathcal{O}(x)) = \dim(G/C_G(x)) = \dim(G) - \dim(C_G(x)) \leq \dim(G) - \text{rank}(G)
\]

for all \( x \in \mathfrak{g} \), so that \( \dim(G) - \text{rank}(G) \) is our new upper bound on adjoint orbit dimensions. This bound is sharp in the sense that \( \mathfrak{g} \) always contains adjoint orbits of dimension \( \dim(G) - \text{rank}(G) \). We defer the proof of this fact to 5.2 (see Corollary 5.8), which is completely independent of the present section.

One calls an adjoint orbit \( \mathcal{O} \subseteq \mathfrak{g} \) regular if \( \dim(\mathcal{O}) = \dim(G) - \text{rank}(G) \).

4.3. Some first results. We now gather some initial results on adjoint orbits, emphasizing connections to semisimple/nilpotent elements and the Jordan decomposition (discussed in 3.2). The facts we establish here will be essential to Sections 5 and 6.

---

3To ensure that \( \mathcal{O}(A) \) from Example 2.13 is an adjoint \( \text{SL}_n(\mathbb{C}) \)-orbit, one must impose the extra condition \( \text{tr}(A) = 0 \).

4Strictly speaking, this reference bounds the dimension of \( C_{\mathfrak{g}}(x) \) instead of \( C_G(x) \). This is, of course, equivalent to the dimension inequality stated here.
Proposition 4.3. If $\emptyset \subseteq \mathfrak{g}$ is an adjoint orbit and $x \in \emptyset$ has Jordan decomposition $x = x_s + x_n$, then $x_s + ax_n \in \emptyset$ for all $a \in \mathbb{C}^*$.

Proof: Since $[x_s, x_n] = 0$, it follows that $x_n \in C_g(x_s)$. However, $C_g(x_s)$ is known to be a reductive subalgebra of $\mathfrak{g}$ (see [57, Prop. 20.5.13]), and one can then deduce that $x_n \in [C_g(x_s), C_g(x_s)]$ (see [57, Prop. 20.5.14]). Also, the fact that $[C_g(x_s), C_g(x_s)]$ is reductive implies that $[C_g(x_s), C_g(x_s)]$ is a semisimple subalgebra. The element $x_n$ is nilpotent in $[C_g(x_s), C_g(x_s)]$, as one can see by embedding $\mathfrak{g}$ (hence also $[C_g(x_s), C_g(x_s)]$) into $\mathfrak{gl}_n(\mathbb{C})$ and applying Theorem 3.3. By the Jacobson-Morozov Theorem, there exists $h \in [C_g(x_s), C_g(x_s)]$ for which $[h, x_n] = 2x_n$. Now for all $c \in \mathbb{C}$, we have
\begin{equation}
\exp(2c) = \exp(\exp(\exp(2c)) = \exp(\exp(\exp(2c)) = \exp(\exp(2c)) = e^{2c}x_n.
\end{equation}

In particular, $x_s + e^{2c}x_n \in \emptyset$ for all $c \in \mathbb{C}$. To prove the proposition as stated, choose $c \in \mathbb{C}$ such that $e^{2c} = a$. □

By letting $a \to 0$ in Proposition 4.3, one obtains the following corollary.

Corollary 4.4. If $\emptyset \subseteq \mathfrak{g}$ is an adjoint orbit and $x \in \emptyset$ has Jordan decomposition $x = x_s + x_n$, then $x_s \in \overline{\emptyset}$.

Our next results will make extensive use of $G$-invariant polynomials on $\mathfrak{g}$. To be more precise, note that the adjoint action induces an action of $G$ on $\mathbb{C}[\mathfrak{g}]$ (cf. Example 2.10), the algebra of regular (i.e., polynomial) functions on $\mathfrak{g}$. Let $\mathbb{C}[\mathfrak{g}]^G \subseteq \mathbb{C}[\mathfrak{g}]$ denote the subalgebra of all $G$-invariant polynomial functions, meaning
\[
\mathbb{C}[\mathfrak{g}]^G := \{ f \in \mathbb{C}[\mathfrak{g}] : g \cdot f = f \text{ for all } g \in G \}.
\]

Analogously, the $W$-action on $t$ (see 3.1) gives rise to a $W$-action on the polynomial functions $\mathbb{C}[t]$, and to a subalgebra $\mathbb{C}[t]^W \subseteq \mathbb{C}[t]$ of $W$-invariant polynomial functions. One can verify that $G$-invariant polynomials on $\mathfrak{g}$ restrict to $W$-invariant polynomials on $t$, and it turns out that this restriction process defines an algebra isomorphism
\begin{equation}
\mathbb{C}[\mathfrak{g}]^G \cong \mathbb{C}[t]^W
\end{equation}
(see [16 Thm. 3.1.38]). Moreover, $\mathbb{C}[\mathfrak{g}]^G$ (hence also $\mathbb{C}[t]^W$) is known to be freely generated as a commutative $\mathbb{C}$-algebra by $r = \text{rank}(G)$ homogeneous polynomials (see [43, Sect. 3.3]).

Proposition 4.5. If $x, y \in \mathfrak{g}$ are semisimple, then $\mathcal{O}(x) = \mathcal{O}(y)$ if and only if $f(x) = f(y)$ for all $f \in \mathbb{C}[\mathfrak{g}]^G$.

Proof: If $\mathcal{O}(x) = \mathcal{O}(y)$, then $y = \text{Ad}_g(x)$ for some $g \in G$ and $f(y) = f(\text{Ad}_g(x)) = f(x)$ for all $f \in \mathbb{C}[\mathfrak{g}]^G$. Conversely, suppose that $f(x) = f(y)$ for all $f \in \mathbb{C}[\mathfrak{g}]^G$. Since $x$ and $y$ are semisimple, there exist $h_x, h_y \in t$ such that $\mathcal{O}(h_x) = \mathcal{O}(x)$ and $\mathcal{O}(h_y) = \mathcal{O}(y)$ (see the discussion in 3.2). Also, repeating the argument from the first sentence of our proof, we see $f(h_x) = f(x)$ and $f(h_y) = f(y)$ for all $f \in \mathbb{C}[\mathfrak{g}]^G$. We may therefore assume that $x, y \in t$. 

\[\]
when proving our converse. It then follows from (22) that \( f(x) = f(y) \) for all \( f \in \mathbb{C}[t]^W \). Using Lemma 34.2.1 of [57], we conclude that \( y = w \cdot x \) for some \( w \in W \). After lifting \( w \) to a representative \( g \in N_G(T) \), this statement becomes \( y = \text{Ad}_g(x) \). Hence \( \mathcal{O}(x) = \mathcal{O}(y) \). \( \square \)

Focusing now on nilpotent elements and adjoint orbits, we have the following.

**Proposition 4.6.** If \( x \in \mathfrak{g} \), then the following conditions are equivalent.

1. \( x \) is nilpotent.
2. For all \( a \in \mathbb{C}^* \), \( ax \in \mathcal{O}(x) \).
3. \( 0 \in \mathcal{O}(x) \).
4. For all \( f \in \mathbb{C}[\mathfrak{g}]^G \), \( f(x) = f(0) \).

**Proof.** We will verify the implications (i) \( \Rightarrow \) (ii) \( \Rightarrow \) (iii) \( \Rightarrow \) (iv) \( \Rightarrow \) (i).

(i) \( \Rightarrow \) (ii): Note that \( x_s = 0 \) and \( x_n = x \), so that (ii) follows immediately from Proposition 4.3.

(ii) \( \Rightarrow \) (iii): If \( ax \in \mathcal{O}(x) \) for all \( a \in \mathbb{C}^* \), letting \( a \to 0 \) establishes that \( 0 \in \mathcal{O}(x) \).

(iii) \( \Rightarrow \) (iv): If \( f \in \mathbb{C}[\mathfrak{g}]^G \), then \( f(\text{Ad}_g(x)) = f(x) \) for all \( g \in G \). In other words, \( f \) takes the constant value \( f(x) \) on \( \mathcal{O}(x) \). By continuity, \( f \) actually takes the constant value \( f(x) \) on \( \mathcal{O}(x) \). Since \( 0 \in \mathcal{O}(x) \), we see that \( f(x) = f(0) \).

(iv) \( \Rightarrow \) (i): For each positive integer \( n \), consider the function \( \phi_n \in \mathbb{C}[\mathfrak{g}] \) defined by \( \phi_n(y) = \text{tr}((\text{ad}_y)^n) \). To see that \( \phi_n \in \mathbb{C}[\mathfrak{g}]^G \), suppose that \( g \in G \) and \( y, z \in \mathfrak{g} \). We have \( \text{ad}_{\text{Ad}_g(y)}(z) = [\text{Ad}_g(y), z] = \text{Ad}_g([y, (\text{Ad}_g)^{-1}(z)]) \), meaning that \( \text{ad}_{\text{Ad}_g(y)} = \text{Ad}_g \circ \text{ad}_y \circ (\text{Ad}_g)^{-1} \). Hence,

\[
\phi_n(\text{Ad}_g(y)) = \text{tr}((\text{ad}_{\text{Ad}_g(y)})^n) = \text{tr}(\text{Ad}_g \circ \text{ad}_y \circ (\text{Ad}_g)^{-1}) = \text{tr}((\text{ad}_y)^n) = \phi_n(y),
\]

and we conclude that \( \phi_n \in \mathbb{C}[\mathfrak{g}]^G \). Now by hypothesis,

\[
\text{tr}((\text{ad}_x)^n) = \phi_n(x) = \phi_n(0) = 0
\]

for all positive integers \( n \). It follows that \( \text{ad}_x \) is a nilpotent endomorphism, as desired. \( \square \)

**4.4. The adjoint quotient.** Adjoint orbits feature prominently in a very natural and well-studied fibration whose total space is \( \mathfrak{g} \). To construct it, one can appeal to the basics of geometric invariant theory. The inclusion \( \mathbb{C}[\mathfrak{g}]^G \hookrightarrow \mathbb{C}[\mathfrak{g}] \) corresponds to a \( G \)-invariant surjective map of affine varieties,

\[
\Phi : \mathfrak{g} \to \text{Spec}(\mathbb{C}[\mathfrak{g}]^G),
\]

(see [51, Sect. 1.4.1, Sect. 1.4.2]), called the *adjoint quotient*. Note \( \text{Spec}(\mathbb{C}[\mathfrak{g}]^G) \) refers to the maximal ideal spectrum of \( \mathbb{C}[\mathfrak{g}]^G \), while \( G \)-invariance is the condition that \( \phi \circ \text{Ad}_g = \phi \) for all \( g \in G \).

One can say a great deal more about (23) by invoking the discussion of \( \mathbb{C}[\mathfrak{g}]^G \) in 4.3. Indeed, recall that \( \mathbb{C}[\mathfrak{g}]^G \) is freely generated by \( r := \text{rank}(G) \) homogeneous generators, \( \chi_1, \chi_2, \ldots, \chi_r \in \mathbb{C}[\mathfrak{g}]^G \). We may therefore identify \( \text{Spec}(\mathbb{C}[\mathfrak{g}]^G) \) with \( \mathbb{C}^r \) and re-write \( \Phi \) as the map

\[
\Phi : \mathfrak{g} \to \mathbb{C}^r, \quad \xi \mapsto (\chi_1(\xi), \chi_2(\xi), \ldots, \chi_r(\xi)).
\]

Kostant studied this form of the adjoint quotient in detail (see [43]). More specifically, note that the \( G \)-invariance of \( \Phi \) is equivalent to each fibre of \( \Phi \) being a union of adjoint orbits. With this in mind, Kostant gave the following description of each fibre’s decomposition into adjoint orbits (see [43 Thm. 0.6, Thm. 0.7]).
**Theorem 4.7.** If \( z \in \text{Spec}(\mathbb{C}[g]^{G}) \), then \( \Phi^{-1}(z) \) is a union of finitely many adjoint orbits and contains a unique regular orbit. This regular orbit is open and dense in \( \Phi^{-1}(z) \).

**Corollary 4.8.** If \( 0 \subseteq g \) is an adjoint orbit, then \( \overline{0} \) is a union of finitely many adjoint orbits.

**Proof.** Choose a point \( x \in 0 \). Since the fibres of \( \Phi \) are \( G \)-invariant, it follows that \( 0 \) belongs to \( \Phi^{-1}(\Phi(x)) \). This fibre is closed, meaning that \( \overline{0} \subseteq \Phi^{-1}(\Phi(x)) \). Theorem 4.7 implies that \( \Phi^{-1}(\Phi(x)) \) is a union of finitely many adjoint orbits, so that the same must be true of \( \overline{0} \). \( \square \)

4.5. **Geometric features.** We now turn our attention to some more inherently geometric aspects of adjoint orbits. However, to avoid the lengthy digressions needed to properly motivate certain definitions, we will sometimes not define the geometric structures under consideration (ex. Poisson and hyperkähler structures). In such cases, we will give suitable references to the research literature.

Consider the coadjoint representation \( \text{Ad}^{*} : G \to \text{GL}(g^{*}), g \mapsto \text{Ad}^{*}_{g} \) defined as follows:

\[
(\text{Ad}^{*}_{g}(\phi))(x) := \phi(\text{Ad}_{g^{-1}}(x)), \quad g \in G, \quad \phi \in g^{*}, \quad x \in g.
\]

This representation gives \( g^{*} \) the structure of a \( G \)-variety, and the resulting orbits are called coadjoint orbits. Moreover, \( g^{*} \) is known to carry a canonical holomorphic Poisson structure whose symplectic leaves are precisely the coadjoint orbits (see [16 Sect. 1.2, 1.3]). It follows that every coadjoint orbit inherits a holomorphic symplectic form, namely a closed, non-degenerate, holomorphic 2-form (see [16 Sect. 1.1] for further details on symplectic forms). One call this particular symplectic form the Kirillov-Kostant-Souriau form.

Now, recall that the Killing form induces a vector space isomorphism \( g \cong g^{*} \). Noting that the Killing form is \( G \)-invariant (see [3.1]), one can verify that our isomorphism is \( G \)-equivariant. Hence, in addition to identifying \( g \) with \( g^{*} \), the isomorphism identifies adjoint orbits with coadjoint orbits. We may therefore transfer the above-mentioned geometric structures on \( g^{*} \) and coadjoint orbits to \( g \) and adjoint orbits, respectively. The Lie algebra \( g \) then has a canonical holomorphic Poisson structure and its symplectic leaves are exactly the adjoint orbits. In particular, every adjoint orbit \( 0 \subseteq g \) carries a preferred holomorphic symplectic form, \( \omega_{0} \in \Omega^{2}(0) \). To describe it, fix \( x \in 0 \) and identify the tangent space \( T_{x}0 \) with \( g/C_{g}(x) \) via \( [5] \), so that the restriction of \( \omega_{0} \) to \( x \) is a bilinear form on \( g/C_{g}(x) \).

We then have

\[
\omega_{0}|_{x} : g/C_{g}(x) \otimes g/C_{g}(x) \to \mathbb{C}, \quad \omega_{0}|_{x}([y],[z]) := \langle x, [y,z] \rangle
\]

for all \([y],[z] \in g/C_{g}(x)\).

Thus far, our treatment of adjoint orbits and geometry has been classical. However, there is a more modern and elaborate framework within which to appreciate the canonical symplectic forms described above – hyperkähler geometry. It turns out that each adjoint orbit is a hyperkähler manifold (see [20] for a definition) whose underlying holomorphic symplectic form is the canonical one we have just described. This result was proved by Kronheimer [46,47] in important special cases and by Biquard [11] and Kovalev [44] in full generality. The key is to identify each adjoint orbit with a certain moduli space of solutions to Nähm’s equations (see [9 Sect. 2.2]), known to be a hyperkähler manifold, and then transfer the hyperkähler structure over to the orbit. It is nevertheless often difficult to describe this induced hyperkähler structure in explicit terms (see [9 Sect 2.3]).
5. Semisimple Orbits

Informally speaking, Example 4.1 shows adjoint orbits to be generalizations of matrix conjugacy classes. In what follows, we will study the adjoint orbits that generalize the conjugacy classes of diagonalizable matrices – the semisimple orbits.

5.1. Definitions and characterizations. Recall from 3.2 that the subvariety of semisimple elements $g_{ss} \subseteq g$ is invariant under the adjoint representation of $G$. One may rephrase this $G$-invariance in the following way: an adjoint orbit contains a semisimple element if and only if it consists of semisimple elements. The adjoint orbits satisfying these equivalent conditions are called the semisimple orbits.

**Definition 5.1.** An adjoint orbit $O \subseteq g$ is called a semisimple orbit if $O \cap g_{ss} \neq \emptyset$, or equivalently $O \subseteq g_{ss}$.

**Example 5.2.** Let $G = SL_n(\mathbb{C})$. Using Example 4.1 and Theorem 3.3, we see that the semisimple orbits in $sl_n(\mathbb{C})$ are precisely the conjugacy classes of semisimple (ie. diagonalizable) $n \times n$ matrices having zero trace.

While we shall take Definition 5.1 to be our definition of a semisimple orbit, there are alternatives. To motivate one of these, recall that Example 2.13 shows the conjugacy class of a diagonal $n \times n$ matrix with pairwise distinct eigenvalues to be closed in $Mat_{n \times n}(\mathbb{C})$. Now suppose that the matrix in question lies in $sl_n(\mathbb{C})$. Its $SL_n(\mathbb{C})$-adjoint orbit is semisimple (see Example 5.2), and the argument from Example 2.13 shows the orbit to be closed in $sl_n(\mathbb{C})$. At the same time, the matrices $N_1$ and $N_2$ from Example 2.13 belong to $sl_n(\mathbb{C})$. Their $SL_n(\mathbb{C})$-adjoint orbits are not semisimple (see Example 5.2 again) and the arguments from Example 2.13 show these orbits to be non-closed in $sl_n(\mathbb{C})$. Our findings here are an instance of a general fact: an adjoint orbit is closed if and only if it is semisimple. Before proving this, we present the following lemma.

**Lemma 5.3.** If $O \subseteq g$ is an adjoint orbit, then there exists a unique semisimple orbit belonging to $O$.

**Proof.** Choose a point $x \in O$. For existence, Corollary 4.4 implies that $x_s \in O$. It follows that $O(x_s)$ is a semisimple orbit lying in $O$. As for uniqueness, suppose that $f \in \mathbb{C}[g]^G$. Since $f(Ad_g(x)) = f(x)$ for all $g \in G$, we see that $f$ is constant-valued on $O$. By continuity, $f$ is actually constant-valued on $O$. In particular, any two semisimple $y, z \in O$ must satisfy $f(y) = f(z)$. By Proposition 4.5, $O(y) = O(z)$. □

**Theorem 5.4.** An adjoint orbit $O \subseteq g$ is semisimple if and only if it is closed in $g$.

**Proof.** Assume that $O$ is semisimple and let $y \in O$ be given. It follows that $O(y) \subseteq O$, or equivalently $O(y) \subseteq O$. Using this together with Corollary 4.4, we see that $y_s \in O$. The orbit $O(y_s)$ is then a semisimple orbit belonging to $O$, and Lemma 5.3 implies that $O = O(y_s)$. We already know that $O(y) \subseteq O$ (ie. $O(y) \subseteq O$), while Corollary 4.4 gives $O(y_s) \subseteq O(y)$ (ie. $O(y_s) \subseteq O(y)$). Hence $O(y) = O$. This implies that $y \in O$, and we conclude that $O$ is closed.
Conversely, assume that $\emptyset$ is closed in $g$ and choose a point $x \in \emptyset$. Corollary 4.4 implies that $x_s \in \overline{O} = \emptyset$, meaning that $\emptyset = \emptyset(x_s)$ is a semisimple orbit. 

**Corollary 5.5.** If $\emptyset \subseteq g$ is a semisimple orbit, then $\emptyset$ is an affine variety.

*Proof.* This follows from the fact that $\emptyset$ is closed in the affine variety $g$. □

### 5.2. Stabilizer descriptions

Recall from [5, 2] that $x \in g$ is semisimple if and only if $\text{Ad}_g(x) \in t$ for some $g \in G$. It follows that an adjoint orbit is semisimple if and only if it is of the form $\emptyset(h)$ for $h \in t$. Now given $h_1, h_2 \in t$, one can show that $\emptyset(h_1) = \emptyset(h_2)$ if and only if $h_1$ and $h_2$ belong to the same $W$-orbit in $t$. We conclude that $[h] \mapsto \emptyset(h)$ defines a bijection from $t/W$ to the set of semisimple orbits. At the same time, each equivalence class in $t/W$ has a unique representative belonging to

$$D := \{ h \in t : \forall \alpha \in \Pi, \text{Re}(\alpha(h)) \geq 0 \text{ and } \text{Re}(\alpha(h)) = 0 \implies \text{Im}(\alpha(h)) \geq 0 \}$$

(see [17], Section 2.2). Our parametrization of semisimple orbits therefore takes the form $h \mapsto \emptyset(h), h \in D$.

Given $h \in D$, we have the following instance of the orbit-stabilizer isomorphism (3):

$$\emptyset(h) \cong G/C_G(h).$$

(27)

In the interest of using (27) to study semisimple orbits, we turn our attention to the structure of $C_G(h)$. To this end, set

$$\Pi(h) := \{ \alpha \in \Pi : \alpha(h) = 0 \}.$$

Recall that $\Pi(h)$ determines a standard parabolic subgroup $P_{\Pi(h)}$ with Levi decomposition $P_{\Pi(h)} = U_{\Pi(h)} \rtimes L_{\Pi(h)}$, as explained in [3, 1].

**Proposition 5.6.** If $h \in D$, then $C_G(h) = L_{\Pi(h)}$.

*Proof.* To begin, note that $P_{\Pi(h)}$ is connected (see [57, Thm. 28.4.2]). It follows that the quotient $P_{\Pi(h)}/U_{\Pi(h)} \cong L_{\Pi(h)}$ is also connected. At the same time, $C_G(h)$ is known to be connected (see [17, Thm. 2.3.3]). Proving $C_G(h) = L_{\Pi(h)}$ therefore amounts to establishing the equality of these groups’ respective Lie algebras $C_g(h)$ and $L_{\Pi(h)}$. To this end, as $t$ is abelian and $h \in t$, we have $t \subseteq C_g(h)$. It follows that $C_g(h)$ decomposes as a direct sum of $t$ and certain root spaces. To determine these root spaces note that $\alpha \in \Delta$ satisfies $g_\alpha \subseteq C_g(h)$ if and only if $\alpha(h) = 0$. Hence,

$$C_g(h) = t \oplus \bigoplus_{\substack{\alpha \in \Delta \\ \alpha(h) = 0}} g_\alpha.$$

Using this together with (12), we are reduced to proving that

$$\Delta_{\Pi(h)} = \{ \alpha \in \Delta : \alpha(h) = 0 \}.$$ 

The inclusion $\Delta_{\Pi(h)} \subseteq \{ \alpha \in \Delta : \alpha(h) = 0 \}$ clearly holds. Conversely, suppose that $\alpha \in \Delta$ satisfies $\alpha(h) = 0$. There exist simple roots $\alpha_1, \ldots, \alpha_k \in \Pi$ and non-zero integers $n_1, \ldots, n_k \in \mathbb{Z} \setminus \{0\}$ such that

$$\alpha = \sum_{i=1}^{k} n_i \alpha_i.$$ (28)
Since \( \alpha(h) = 0 \), we have

\[
0 = \sum_{i=1}^{k} n_i \alpha_i(h).
\]

In particular, \(0 = \sum_{i=1}^{k} n_i \text{Re}(\alpha_i(h))\). Now, recall from (26) that \(\text{Re}(\alpha_i(h)) \geq 0\) for all \(i\), and note that all \(n_i\) are strictly positive or all \(n_i\) are strictly negative. It follows that \(\text{Re}(\alpha_i(h)) = 0\) for all \(i\). Noting that \(h \in \mathcal{D}\), it must be true that \(\text{Im}(\alpha_i(h)) \geq 0\) for all \(i\).

Also, taking imaginary parts in (30) gives \(0 = \sum_{i=1}^{k} n_i \text{Im}(\alpha_i(h))\). Again using the fact that all \(n_i\) are strictly positive or all \(n_i\) are strictly negative, it follows that \(\text{Im}(\alpha_i(h)) = 0\) for all \(i\). We conclude that \(\alpha_i(h) = 0\) (i.e. \(\alpha_i \in \Pi(h)\)) for all \(i\), which by (29) implies \(\alpha \in \Delta_{\Pi(h)}\).

Having shown (28) to hold, our proof is complete. \(\square\)

Proposition 5.6 gives rise to the following more uniform description of the stabilizers of semisimple elements.

**Corollary 5.7.** If \(x \in \mathfrak{g}\) is semisimple, then \(C_G(x)\) is a Levi factor of a parabolic subgroup of \(G\).

**Proof.** Since \(x\) is semisimple, \(x = \text{Ad}_g(h)\) for some \(g \in G\) and \(h \in \mathcal{D}\). It follows that \(C_G(x) = gC_G(h)g^{-1}\), which by Proposition 5.6 is precisely \(gL_{\Pi(h)}g^{-1}\). This is a Levi factor of the parabolic subgroup \(gP_{\Pi(h)}g^{-1}\). \(\square\)

We conclude this section with a proof of the existence of regular adjoint orbits, as promised in 4.2.

**Corollary 5.8.** There exist regular adjoint orbits in \(\mathfrak{g}\).

**Proof.** Let \(\{e_\alpha\}_{\alpha \in \Pi}\) and \(h \in \mathfrak{t}\) be as defined in Example 5.7. Since \(\alpha(h) = 2\) for all \(\alpha \in \Pi\), we see that \(h \in \mathcal{D}\) and \(\Pi(h) = \emptyset\). It follows that \(L_{\Pi(h)} = \mathfrak{t}\) (see (12)), which together with the connectedness of \(L_{\Pi(h)}\) (established in the proof of Proposition 5.6) implies that \(L_{\Pi(h)} = T\). Now the orbit-stabilizer isomorphism (27) and Proposition 5.6 give

\[
\dim(\Omega(h)) = \dim(G/T) = \dim(G) - \dim(T) = \dim(G) - \text{rank}(G).
\]

In other words, \(\Omega(h)\) is a regular adjoint orbit. \(\square\)

### 5.3. Fibrations over partial flag varieties.

Consider a point \(h \in \mathcal{D}\), to be regarded as fixed throughout 5.3 and recall the variety isomorphism \(O(h) \cong G/C_G(h)\) in (27). Proposition 5.6 allows us to write the right-hand-side of this isomorphism as \(G/L_{\Pi(h)}\), and the inclusion \(L_{\Pi(h)} \subseteq P_{\Pi(h)}\) gives rise to a fibration \(U_{\Pi(h)} \rightarrow G/L_{\Pi(h)} \rightarrow G/P_{\Pi(h)}\). In other words, we have a canonical fibre bundle

\[
U_{\Pi(h)} \rightarrow \Omega(h) \xrightarrow{\pi_h} G/P_{\Pi(h)},
\]

where \(\pi_h(\text{Ad}_g(h)) = [g] \in G/P_{\Pi(h)}\) for all \(g \in G\).

The fibre \(U_{\Pi(h)}\) is unipotent, so that the exponential map restricts to a variety isomorphism \(u_{\Pi(h)} : U_{\Pi(h)} \cong \mathbb{A}^{n(h)}\) (see [34] Chapt. VIII, Thm. 1.1]). It follows that the fibres of (31) are affine spaces, raising the issue of whether \(\Omega(h)\) is isomorphic to the total space of a vector bundle over \(G/P_{\Pi(h)}\). Perhaps surprisingly, one cannot expect an isomorphism on the level of algebraic varieties. The total space of a vector bundle over \(G/P_{\Pi(h)}\) contains \(G/P_{\Pi(h)}\) as the zero-section, and one knows \(G/P_{\Pi(h)}\) to be irreducible (since \(G\) is irreducible) and projective (see [37], Cor. 28.1.4). It follows that the zero-section is a closed,
irreducible, projective subvariety. However, the only a such subvarieties of the affine variety \( \mathcal{O}(h) \) are the singletons. A similar argument precludes the existence of a biholomorphism, as a compact, connected, complex submanifold of the Stein manifold \( \mathcal{O}(h) \) is necessarily a point. Nevertheless, it turns out that there is a diffeomorphism between \( \mathcal{O}(h) \) and (the total space of) \( T^*(G/P_{\Pi(h)}) \) that respects fibrations over \( G/P_{\Pi(h)} \). We devote the balance of \(^5\) to an explicit construction of this diffeomorphism.

**Remark 5.9.** By invoking well-known facts from hyperkähler geometry, one can deduce that \( \mathcal{O}(h) \) and \( T^*(G/P_{\Pi(h)}) \) are diffeomorphic without having to construct a diffeomorphism. To this end, recall that \( \mathcal{O}(h) \) is a hyperkähler manifold (see \[4.5\]). Among other things, it follows that the underlying smooth manifold \( \mathcal{O}(h) \) carries a family of complex structures. This family turns out to include the usual complex structure on \( \mathcal{O}(h) \) (i.e. the one it inherits as a subvariety of \( g \)), as well as one in which \( \mathcal{O}(h) \) becomes biholomorphic to \( T^*(G/P_{\Pi(h)}) \) (see \[11\] Thm. 2]). One concludes that \( \mathcal{O}(h) \) and \( T^*(G/P_{\Pi(h)}) \) must be diffeomorphic. While this approach is elegant, it is difficult to extract an explicit diffeomorphism \( \mathcal{O}(h) \cong T^*(G/P_{\Pi(h)}) \) from the supporting arguments.

Let \( K \subseteq G \) be a maximal compact subgroup having \( K \cap T \) as a maximal real torus. We shall assume the Lie algebra \( \mathfrak{k} \) of \( K \) to have the form

\[
\mathfrak{t} = (\mathfrak{t} \cap \mathfrak{t}) \oplus \left( \bigoplus_{\alpha \in \Delta_c} \text{span}_{\mathbb{R}} \{ e_\alpha - e_{-\alpha} \} \right) \oplus \left( \bigoplus_{\alpha \in \Delta_c} \text{span}_{\mathbb{R}} \{ i(e_\alpha + e_{-\alpha}) \} \right),
\]

where \( e_\alpha \in \mathfrak{g}_\alpha \setminus \{0\} \) and \( e_{-\alpha} \in \mathfrak{g}_{-\alpha} \setminus \{0\} \) for each \( \alpha \in \Delta_c \) (cf. the proof of Theorem 6.11 in \[40\]). Now note that \( K \) acts transitively on \( G/P_{\Pi(h)} \) by left multiplication (see \[49\] Chapt. 5, Sect. 8]), and that the \( K \)-stabilizer of the identity coset \( [e] \in G/P_{\Pi(h)} \) is \( K \cap P_{\Pi(h)} =: K_{\Pi(h)} \). By the orbit-stabilizer isomorphism \(^3\), this time for compact Lie group actions, we have a \( K \)-equivariant diffeomorphism

\[
K/K_{\Pi(h)} \cong G/P_{\Pi(h)}.
\]

We will later need the following result concerning \( K_{\Pi(h)} \).

**Lemma 5.10.** We have \( K_{\Pi(h)} \subseteq L_{\Pi(h)} \).

**Proof.** We begin by showing \( K_{\Pi(h)} \) to be connected. To this end, consider the fibration \( K_{\Pi(h)} \to K \to K/K_{\Pi(h)} \). The base is simply-connected by virtue of being diffeomorphic to \( G/P_{\Pi(h)} \), a simply-connected space (see \[11\] Chapt. 3, Sect. 1, Prop. 7]). The total space \( K \) is homotopy-equivalent to \( G \) (see \[59\] Appendix A, Thm. 1.1]), so that the connectedness of \( K \) follows from that of \( G \). Using these two observations together with the long exact sequence of homotopy groups associated to our fibration (see \[59\] Chapt. IV, Cor. 8.6]), we see that \( K_{\Pi(h)} \) is also connected. It will therefore suffice to prove that \( \mathfrak{k}_{\Pi(h)} \subseteq \mathfrak{t}_{\Pi(h)} \), where \( \mathfrak{k}_{\Pi(h)} \) and \( \mathfrak{t}_{\Pi(h)} \) are the Lie algebras of \( K_{\Pi(h)} \) and \( L_{\Pi(h)} \), respectively. The former Lie algebra is \( \mathfrak{t} \cap \mathfrak{p}_{\Pi(h)} \), which via \( \mathfrak{t} \cap \mathfrak{p}_{\Pi(h)} \) and \( \mathfrak{t} \cap \mathfrak{p}_{\Pi(h)} \) can be shown to coincide with

\[
(\mathfrak{t} \cap \mathfrak{t}) \oplus \left( \bigoplus_{\alpha \in \Delta_{\Pi(h)}^c} \text{span}_{\mathbb{R}} \{ e_\alpha - e_{-\alpha} \} \right) \oplus \left( \bigoplus_{\alpha \in \Delta_{\Pi(h)}^c} \text{span}_{\mathbb{R}} \{ i(e_\alpha + e_{-\alpha}) \} \right).
\]
Since \( t \subseteq t_{\Pi(h)} \) and \( g_\alpha \oplus g_{-\alpha} \subseteq t_{\Pi(h)} \) for all \( \alpha \in \Delta^+_{\Pi(h)} \) (see [12]), it follows that \( t_{\Pi(h)} \subseteq t_{\Pi(h)} \).

Let us return to the main discussion. Note that the pullback of \( T^*(G/P_{\Pi(h)}) \) under \((33)\) is a smooth complex vector bundle \( E \to K/K_{\Pi(h)} \), so that we have the commutative diagram

\[
\begin{array}{ccc}
E & \cong & T^*(G/P_{\Pi(h)}) \\
\downarrow & & \downarrow \\
K/K_{\Pi(h)} & \cong & G/P_{\Pi(h)}
\end{array}
\]  

(34)

One can show \( E \) to be a \( K \)-equivariant vector bundle, meaning that \( K \) acts smoothly on \( E \) via a lift of the left multiplication action on \( K/K_{\Pi(h)} \) (hence \( k \in K \) sends the fibre over \( x \in K/K_{\Pi(h)} \) to the fibre over \( k \cdot x \)), and secondly that restricting the action of \( k \in K \) to the fibre over \( x \in K/K_{\Pi(h)} \) gives a vector space isomorphism with the fibre over \( k \cdot x \). Since the identity coset \([e] \in K/K_{\Pi(h)}\) is fixed by \( K_{\Pi(h)} \), this second condition implies that the fibre over \([e]\) in any \( K \)-equivariant vector bundle is a complex \( K_{\Pi(h)} \)-representation. In fact, this turns out to define a bijective correspondence between isomorphism classes of (smooth) complex \( K_{\Pi(h)} \)-representations and isomorphism classes of smooth \( K \)-equivariant complex vector bundles over \( K/K_{\Pi(h)} \). The inverse process assigns to each representation \( \varphi : K_{\Pi(h)} \to \text{GL}(V) \) the associated bundle \( K \times_{K_{\Pi(h)}} V \), defined as follows. The group \( K_{\Pi(h)} \) acts freely on \( K \times V \) via \( g \cdot (k, v) = (kg^{-1}, \varphi(g)v) \), \( g \in K_{\Pi(h)} \), \( k \in K \), \( v \in V \). One defines \( K \times_{K_{\Pi(h)}} V \) to be the quotient manifold \((K \times V)/K_{\Pi(h)} \), equipped with the projection to \( K/K_{\Pi(h)} \) given by \([([k, v]) \mapsto [k] \). The fibres of this projection are naturally complex vector spaces, and the \( K \)-equivariant structure comes from the left-multiplicative action of \( K \) on the first factor of \( K \times_{K_{\Pi(h)}} V \).

With the above discussion in mind, it is natural to realize \( E \) as an associated bundle. To this end, \( U_{\Pi(h)} \) is a normal subgroup of \( P_{\Pi(h)} \) by virtue of the former being the unipotent radical of the latter. It follows that \( u_{\Pi(h)} \) is invariant under \( P_{\Pi(h)} \) (hence also the subgroup \( K_{\Pi(h)} \)), acting through the adjoint representation of \( G \). In particular, \( u_{\Pi(h)} \) is a \( K_{\Pi(h)} \)-representation.

**Lemma 5.11.** There is an isomorphism \( E \cong K \times_{K_{\Pi(h)}} u_{\Pi(h)} \) of \( K \)-equivariant vector bundles over \( K/K_{\Pi(h)} \).

**Proof.** Given our discussion of the correspondence between isomorphism classes of \( K \)-equivariant vector bundles and those of \( K_{\Pi(h)} \)-representations, it will suffice to prove that \( u_{\Pi(h)} \) is isomorphic to the fibre of \( E \) over \([e] \in K/K_{\Pi(h)} \) as a \( K_{\Pi(h)} \)-representation. The latter is the dual of the tangent space to \([e] \in G/P_{\Pi(h)} \), which by \((5)\) (with \( \mathcal{O} = G/P_{\Pi(h)} \) is isomorphic to \( (g/P_{\Pi(h)})^* \). One can identify \( (g/P_{\Pi(h)})^* \) with \( \{\phi \in g^* : \phi|_{P_{\Pi(h)}} = 0\} \), which under our isomorphism \( g^* \cong g \) corresponds to \( \{x \in g : [x, y] = 0 \text{ for all } y \in p_{\Pi(h)}\} \). This last subspace can be seen to coincide with \( u_{\Pi(h)} \), as desired. We leave it as an exercise for the reader to verify that each of the above-constructed isomorphisms is an isomorphism of \( P_{\Pi(h)} \) (hence also \( K_{\Pi(h)} \)-) representations.

Using Lemma 5.11 we may present \((34)\) as
\[ K \times_{K_{\Pi(h)}} u_{\Pi(h)} \xrightarrow{\cong} T^* (G/P_{\Pi(h)}) \]

\[ \Downarrow \quad \Downarrow \]

\[ K/K_{\Pi(h)} \xrightarrow{\cong} G/P_{\Pi(h)}. \]

**Proposition 5.12.** There is a $K$-equivariant diffeomorphism $T^* (G/P_{\Pi(h)}) \cong \mathcal{O}(h)$ for which the following diagram commutes:

\[ T^* (G/P_{\Pi(h)}) \xrightarrow{\cong} \mathcal{O}(h) \]

\[ \Downarrow \quad \Downarrow_{\pi_h} \]

\[ G/P_{\Pi(h)} \]

*Proof.* We will construct a $K$-equivariant diffeomorphism $K \times_{K_{\Pi(h)}} u_{\Pi(h)} \xrightarrow{\cong} \mathcal{O}(h)$ making

\[ K \times_{K_{\Pi(h)}} u_{\Pi(h)} \xrightarrow{\cong} \mathcal{O}(h) \]

\[ \Downarrow \quad \Downarrow_{\pi_h} \]

\[ K/K_{\Pi(h)} \xrightarrow{\cong} G/P_{\Pi(h)} \]

commute. By reversing the horizontal arrows in (35) and combining with (37), we will have constructed the desired isomorphism $T^*(G/P_{\Pi(h)}) \cong \mathcal{O}(h)$. Accordingly, let $K \times_{K_{\Pi(h)}} (P_{\Pi(h)}/L_{\Pi(h)})$ denote the quotient of $K \times (P_{\Pi(h)}/L_{\Pi(h)})$ by the $K_{\Pi(h)}$-action $g \cdot (k, [p]) = (kg^{-1}, [gp])$, $g \in K$, $k \in K$, $p \in P_{\Pi(h)}$. The proof of Lemma 2.4 in [2] shows the map

\[ K \times_{K_{\Pi(h)}} (P_{\Pi(h)}/L_{\Pi(h)}) \to G/L_{\Pi(h)}, \quad ([k, [p]]) \mapsto [kp] \]

(38)

to be a (well-defined) diffeomorphism. In the interest of re-writing (38), recall that $L_{\Pi(h)} = C_G(h)$ (see Proposition 5.6). One therefore has the orbit-stabilizer isomorphism

\[ G/L_{\Pi(h)} \cong \mathcal{O}(h), \quad [g] \mapsto \text{Ad}_g(h). \]

(39)

As for the domain of (38), note that the Levi factorization (111) implies $U_{\Pi(h)} \to P_{\Pi(h)}/L_{\Pi(h)}$, $u \mapsto [u]$, is a variety isomorphism. Identifying $U_{\Pi(h)}$ with $u_{\Pi(h)}$ via the exponential map, this isomorphism becomes

\[ u_{\Pi(h)} \to P_{\Pi(h)}/L_{\Pi(h)}, \quad x \mapsto [\exp(x)]. \]

(40)

Since $K_{\Pi(h)} \subseteq L_{\Pi(h)}$ (see Lemma 5.10) and $\exp(\text{Ad}_g(x)) = g \exp(x)g^{-1}$ for all $g \in K_{\Pi(h)}$ and $x \in u_{\Pi(h)}$, one can show (40) to be $K_{\Pi(h)}$-equivariant. This allows us to replace $P_{\Pi(h)}/L_{\Pi(h)}$ in (38) with $u_{\Pi(h)}$, giving rise to the diffeomorphism

\[ K \times_{K_{\Pi(h)}} u_{\Pi(h)} \to K \times_{K_{\Pi(h)}} (P_{\Pi(h)}/L_{\Pi(h)}), \quad [[k, x]] \mapsto [[k, \exp(x)]] \]

(41)

Now composing the three diffeomorphisms (38), (39), and (41) (in the only order that makes sense), we obtain

\[ K \times_{K_{\Pi(h)}} u_{\Pi(h)} \to \mathcal{O}(h), \quad [[k, x]] \mapsto \text{Ad}_{k \exp(x)}(h). \]

(42)
This diffeomorphism is clearly $K$-equivariant. To see that it makes (37) commute, note that the composite map $K \times_{K_l(h)} u_l(h) \to K/K_l(h) \to G/P_l(h)$ sends $[[k, x]] \in K \times_{K_l(h)} u_l(h)$ to $[k] \in G/P_l(h)$. On the other hand, the composite map $K \times_{K_l(h)} u_l(h) \to O(h) \to G/P_l(h)$ sends $[[k, x]] \in K \times_{K_l(h)} u_l(h)$ to $[k \exp(x)] \in G/P_l(h)$. However, since $x \in u_l(h) \subseteq p_l(h)$, we must have $\exp(x) \in P_l(h)$. It follows that $[k \exp(x)] = [k]$ in $G/P_l(h)$, so that (37) indeed commutes. This completes the proof.

Proposition 5.12 has strong implications for the topology (both equivariant and non-equivariant) of a semisimple orbit.

Corollary 5.13. There is a $K$-equivariant homotopy equivalence between $O(h)$ and the compact group orbit $O_K(h) = K \cdot h$.

Proof. Note that $K \times_{K_l(h)} u_l(h)$ is $K$-equivariantly homotopy equivalent to its zero-section. Since (42) is a $K$-equivariant diffeomorphism, it follows that the image of the zero-section under (42) is $K$-equivariantly homotopy equivalent to $O(h)$. The zero-section is given by $\{[[k, 0]] \in K \times_{K_l(h)} u_l(h) : k \in K\}$, and its image under (42) is the $K$-orbit $O_K(h) \subseteq O(h)$. This completes the proof.

An essentially analogous version of Corollary 5.13 is as follows. The cotangent bundle projection $T^*(G/P_l(h)) \to G/P_l(h)$ is a $K$-equivariant (in fact, $G$-equivariant) homotopy equivalence, so that (36) shows $\pi_h : O(h) \to G/P_l(h)$ to be a $K$-equivariant homotopy equivalence. In principle, one can use this fact to compute various topological invariants of $O(h)$. Indeed, since $G/P_l(h)$ is simply-connected (as discussed in the proof of Lemma 5.10), so too is $O(h)$. Secondly, the cohomology ring $H^*(O(h); \mathbb{Z})$ is isomorphic to $H^*(G/P_l(h); \mathbb{Z})$, which has a well-studied description in terms of Schubert calculus (see [7]). This result has an equivariant counterpart, namely that the $L$-equivariant cohomology rings $H^*_L(O(h); \mathbb{Z})$ and $H^*_L(G/P_l(h); \mathbb{Z})$ are isomorphic for any closed subgroup $L \subset K$ (see [14] for details on equivariant cohomology). If one takes $L$ to be the maximal torus $K \cap T$ of $K$, then $H^*_L(G/P_l(h); \mathbb{Z})$ is describable via equivariant Schubert calculus (see [30, 50]) and (if one works over $\mathbb{C}$ instead of $\mathbb{Z}$) Goresky-Kottwitz-MacPherson (GKM) theory (see [32]).

5.4. Equivariant projective compactifications. While semisimple orbits are affine (see Corollary 5.5), each turns out to admit a $G$-equivariant projective compactification (ie. a projective $G$-variety $X$ and a $G$-variety isomorphism between the orbit and an invariant open dense subvariety of $X$). To properly construct this compactification, however, we will need a few preliminary results. Let $w_0 \in W$ denote the longest element of the Weyl group (see [15, Chapt. 20]). It is known that $w_0 \cdot \Pi = -\Pi$, so that $S \mapsto S^\vee := -w_0 \cdot S$ defines an involution on the collection of subsets $S \subseteq \Pi$. With this in mind, we have the following lemma.

Lemma 5.14. For $S \subseteq \Pi$, we have $w_0 \cdot \Delta^-_{S^\vee} = \Delta^+_{S^\vee}$.

Proof. Let us write $S = \{\alpha_1, \ldots, \alpha_n\}$, so that $S^\vee = \{\gamma_1, \ldots, \gamma_n\}$ with $\gamma_i = -w_0 \cdot \alpha_i$ for all $i$. Given $\beta \in \Delta^+_S$, we have $\beta = \sum_{i=1}^n k_i \alpha_i$ with $k_1, \ldots, k_n \in \mathbb{Z}_{\geq 0}$. It follows that

$$w_0 \cdot \beta = \sum_{i=1}^n (-k_i)(-w_0 \cdot \alpha_i) = \sum_{i=1}^n (-k_i)\gamma_i.$$
Since \( w_0 \cdot \beta \) is a root, this implies that \( w_0 \cdot \beta \in \Delta_+^\circ \). Using the fact that \( w_0^2 = e \), we have \( \beta \in w_0 \cdot \Delta_-^\circ \).

Conversely, if \( \beta \in w_0 \cdot \Delta_-^\circ \), then \( \beta = w_0 \cdot (\sum_{i=1}^n k_i \gamma_i) \) with \( k_1, \ldots, k_n \in \mathbb{Z}_{\leq 0} \). We conclude that

\[
\beta = w_0 \cdot \left( \sum_{i=1}^n k_i (-w_0 \cdot \alpha_i) \right) = \sum_{i=1}^n (-k_i) \alpha_i.
\]

Noting that \( \beta \) is a root, this implies that \( \beta \in \Delta_-^\circ \).

Given \( S \subseteq \Pi \), the subset \( S^\vee \subseteq \Pi \) determines a standard parabolic subgroup \( P_{S^\vee} \subseteq G \) (as discussed in [3,1]). Now consider the parabolic subgroup \( P^*_S \subseteq G \) defined by

\[
P^*_S := w_0 P_{S^\vee} (w_0)^{-1},
\]

where \( w_0 P_{S^\vee} (w_0)^{-1} := g P_{S^\vee} g^{-1} \) for any representative \( g \in N_G(T) \) of \( w_0 \).

**Proposition 5.15.** For \( S \subseteq \Pi \), we have \( P_S \cap P^*_S = L_S \).

**Proof.** Since \( L_S \) and \( P_S \cap P^*_S \) are connected (the former by the beginning of the proof of Proposition 5.6 and the latter by [21, Prop. 2.1]), it suffices to establish the equality of their respective Lie algebras. The latter Lie algebra is precisely \( p_S \cap w_0 \cdot p_{S^\vee} \), where \( w_0 \cdot p_{S^\vee} \) denotes the adjoint action of a lift of \( w_0 \) to \( N_G(T) \). This intersection contains \( t \) and therefore decomposes as a direct sum of \( t \) and the root spaces belonging to both \( p_S \) and \( w_0 \cdot p_{S^\vee} \). To identify these root spaces, note that

\[
p_S = t \oplus \left( \bigoplus_{\alpha \in \Delta_+} g_\alpha \right) \oplus \left( \bigoplus_{\alpha \in \Delta_-^\circ} g_\alpha \right),
\]

and

\[
w_0 \cdot p_{S^\vee} = t \oplus \left( \bigoplus_{\alpha \in w_0 \cdot \Delta_+^\circ} g_\alpha \right) \oplus \left( \bigoplus_{\alpha \in w_0 \cdot \Delta_-^\circ} g_\alpha \right).
\]

Since \( w_0 \cdot \Delta_+ = \Delta_+ \) (see [15, Prop. 20.14]) and \( w_0 \cdot \Delta_-^\circ = \Delta_-^\circ \) (by Lemma 5.14), we may re-write (45) to obtain

\[
w_0 \cdot p_{S^\vee} = t \oplus \left( \bigoplus_{\alpha \in \Delta_+^\circ} g_\alpha \right) \oplus \left( \bigoplus_{\alpha \in \Delta_-} g_\alpha \right).
\]

Using (44) and (46), we conclude that

\[
p_S \cap w_0 \cdot p_{S^\vee} = t \oplus \left( \bigoplus_{\alpha \in \Delta_+^\circ} g_\alpha \right) \oplus \left( \bigoplus_{\alpha \in \Delta_-} g_\alpha \right) = l_S,
\]

the Lie algebra of \( L_S \). This completes the proof. \( \Box \)

Returning to the discussion of equivariant projective orbit compactifications, fix \( h \in T \) and consider its semisimple orbit \( O(h) \). Also, let \( X \) be any \( G \)-variety. By means of (39), a \( G \)-variety isomorphism between \( O(h) \) and an invariant subvariety \( Y \subseteq X \) is equivalent
to a G-variety isomorphism between $G/L_{\Pi(h)}$ and $Y$. Now by the general orbit-stabilizer theory developed in \[2,3\], specifying the latter isomorphism is equivalent to specifying a point $x \in X$ with $C_G(x) = L_{\Pi(h)}$. In this case, $G/L_{\Pi(h)}$ (hence $\mathcal{O}(h)$) is equivariantly identified with the $G$-orbit of $x$ in $X$.

In light of the above, we seek a projective G-variety $X$ and a point $x \in X$ with $C_G(x) = L_{\Pi(h)}$. To this end, consider the diagonal $G$-action (see Example 2.6) on the projective variety $X = G/P_{\Pi(h)} \times G/P_{\Pi(h)}^*$. Consider also the pair of identity cosets $x = ([e], [e]) \in X$. The $G$-stabilizer of $x$ is $P_{\Pi(h)} \cap P_{\Pi(h)}^*$, which by Proposition 5.15 is precisely $L_{\Pi(h)}$. Appealing to the previous paragraph, the following is a G-variety isomorphism between $\mathcal{O}(h)$ and the $G$-orbit $G \cdot ([e], [e]) \subseteq G/P_{\Pi(h)} \times G/P_{\Pi(h)}^*$:

\[ (47) \quad \mathcal{O}(h) \xrightarrow{\sim} G \cdot ([e], [e]), \quad \text{Ad}_g(h) \mapsto ([g], [g]), \quad g \in G. \]

**Theorem 5.16.** If $h \in \mathcal{D}$, then (47) makes $G/P_{\Pi(h)} \times G/P_{\Pi(h)}^*$ a $G$-equivariant projective compactification of $\mathcal{O}(h)$.\(^6\)

**Proof.** It remains only to prove that $G \cdot ([e], [e])$ is open and dense in $G/P_{\Pi(h)} \times G/P_{\Pi(h)}^*$. However, since $G \cdot ([e], [e])$ is open in its closure (see 2.2), it will suffice to prove that $G \cdot ([e], [e]) = G/P_{\Pi(h)} \times G/P_{\Pi(h)}^*$. Now note that $G/P_{\Pi(h)} \times G/P_{\Pi(h)}^*$ is irreducible, so that it has no proper irreducible closed subvarieties of codimension zero (see \[36\] Sect. 3.2]).

We are therefore reduced to proving that $G \cdot ([e], [e])$ and $G/P_{\Pi(h)} \times G/P_{\Pi(h)}^*$ have equal dimensions. The dimension of the former equals that of its open subvariety $G \cdot ([e], [e])$, which by (47) equals $\text{dim}(\mathcal{O}(h))$. Proposition 5.12 implies $\text{dim}(\mathcal{O}(h)) = 2 \cdot \text{dim}(G/P_{\Pi(h)})$, so that we have

\[ (48) \quad \text{dim}(G \cdot ([e], [e])) = 2 \cdot \text{dim}(G/P_{\Pi(h)}). \]

At the same time, we have

\[ (49) \quad \text{dim}(G/P_{\Pi(h)} \times G/P_{\Pi(h)}^*) = \text{dim}(G/P_{\Pi(h)}) + \text{dim}(G/P_{\Pi(h)}^*). \]

In light of (48) and (49), it will be enough to prove that $\text{dim}(G/P_{\Pi(h)}) = \text{dim}(G/P_{\Pi(h)}^*)$ (or equivalently, $\text{dim}(P_{\Pi(h)}) = \text{dim}(P_{\Pi(h)}^*)$). To this end, Lemma 5.14 implies that $\Delta^+_\Pi(h)$ and $\Delta^-_{\Pi(h)}\!^\vee$ have the same cardinality. Of course, since $\Delta^+_\Pi(h) = -\Delta^-_{\Pi(h)}\!^\vee$ this is equivalent to $\Delta^+_\Pi(h)$ and $\Delta^-_{\Pi(h)}\!^\vee$ having the same cardinality. Now (10) implies that $\text{dim}(P_{\Pi(h)}) = \text{dim}(P_{\Pi(h)}\!^\vee)$, which one can re-write as $\text{dim}(P_{\Pi(h)}) = \text{dim}(P_{\Pi(h)}\!^\vee)$. Finally, since $P_{\Pi(h)}^*$ was defined to be a conjugate of $P_{\Pi(h)}\!^\vee$ (see (43)), the dimensions of $P_{\Pi(h)}$ and $P_{\Pi(h)}^*$ must also agree. Hence $\text{dim}(P_{\Pi(h)}) = \text{dim}(P_{\Pi(h)}^*)$, as desired. \(\square\)

**Remark 5.17.** The compactification in Theorem 5.16 turns out to have some context in the homological mirror symmetry program (see [29], [35] for an introduction to this program). Vaguely speaking, an instance of homological mirror symmetry is an equivalence between symplecto-geometric data on a smooth manifold (called the A-side of the symmetry) and algebro-geometric data on a projective variety (called the B-side of the symmetry). In [3], the authors interpret this as a symmetry between so-called A-side Landau-Ginzburg (LG) models and B-side LG models (see 3 Sect. 1) for further details. Building on an existing interpretation of a semisimple orbit $\mathcal{O}(h)$ as an A-side LG model

\[\]
explained in [3, Sect. 1] and based on [26, Thm. 2.2]), the authors explain how one would make \( G/P_{\Pi(h)} \times G/P_{\Pi(h)} \) into the corresponding \( B \)-side model.

6. NILPOTENT ORBITS

Recall that we introduced semisimple orbits as generalizing the conjugacy classes of diagonalizable matrices. We now discuss the appropriate generalization of a nilpotent conjugacy class – a nilpotent orbit.

6.1. Definitions and first results. Recall that the nilpotent cone \( N \subseteq g \) is invariant under the adjoint action of \( G \) (see 3.2). It follows that \( N \) is a union of those adjoint orbits \( O \) for which \( O \cap N \neq \emptyset \) (ie. \( O \) contains a nilpotent element). Such adjoint orbits will be called nilpotent orbits.

**Definition 6.1.** An adjoint orbit \( O \subseteq g \) is called a nilpotent orbit if \( O \cap N \neq \emptyset \), or equivalently \( O \subseteq N \).

While this is generally taken to be the definition of a nilpotent orbit, there are several equivalent descriptions. Indeed, one can rephrase Proposition 4.6 in the language of adjoint orbits as follows.

**Proposition 6.2.** If \( O \subseteq g \) is an adjoint orbit, then the following conditions are equivalent.

(i) \( O \) is a nilpotent orbit.

(ii) \( O \) is invariant under the dilation action of \( \mathbb{C}^* \) on \( g \).

(iii) \( 0 \in O \).

(iv) For all \( f \in \mathbb{C}[g]^G \), \( f \) takes the constant value \( f(0) \) on \( O \).

**Example 6.3.** Let \( G = \text{SL}_n(\mathbb{C}) \). By Theorem 3.3 and Example 4.1 the nilpotent orbits in \( \mathfrak{sl}_n(\mathbb{C}) \) are exactly the conjugacy classes of the nilpotent \( n \times n \) matrices (which necessarily have zero trace). These conjugacy classes are in turn indexed by the nilpotent \( n \times n \) matrices in Jordan canonical form, modulo permutations of Jordan blocks along the diagonal. Of course, each of these equivalence classes of nilpotent Jordan matrices has a unique representative whose block heights, read from top to bottom, form a non-decreasing sequence. The sequences one obtains in this way are precisely the partitions of \( n \), ie. the positive integer sequences \( \lambda = (\lambda_1, \lambda_2, \ldots, \lambda_k), 1 \leq k \leq n \), satisfying \( \lambda_1 \geq \lambda_2 \geq \ldots \geq \lambda_k \) and \( \lambda_1 + \lambda_2 + \ldots + \lambda_k = n \). It follows that the nilpotent orbits in \( \mathfrak{sl}_n(\mathbb{C}) \) are explicitly parametrized by the partitions of \( n \). In particular, there are only finitely many nilpotent \( \text{SL}_n(\mathbb{C}) \)-orbits.

This last point about finiteness turns out to hold in much greater generality. More precisely, it turns out there are only finitely many nilpotent \( G \)-orbits. The proof of this fact, however, is far more complicated than what appears in Example 6.3. One approach uses ideas related to the Springer resolution and Steinberg variety (see [16, Sect. 3.3] for more details). Another strategy is to classify nilpotent orbits using so-called “weighted Dynkin diagrams” and appeal to the fact that there are only finitely many of the latter (see [17, Chapt. 3]). Here, we will see the finiteness of nilpotent orbits as a direct consequence of Kostant’s work on the adjoint quotient.

**Theorem 6.4.** There are only finitely many nilpotent orbits.
Proof. Recall the description of the adjoint quotient given in (24). It will suffice to prove that \( \Phi^{-1}(0) = N \), since Theorem 4.7 will then show \( N \) to be a union of finitely many adjoint orbits. To this end, Proposition 4.6 implies that \( x \in g \) is nilpotent if and only if \( f(x) = f(0) \) for all \( f \in C[g]^0 \). Letting \( X_1, X_2, \ldots, X_r \subset C[g]^0 \) be the homogeneous generators mentioned in [4.4], this is equivalent to \( X_j(x) = 0 \) for all \( j = 1, \ldots, n \), i.e. \( \Phi(x) = 0 \). The preceding argument establishes that \( \Phi^{-1}(0) = N \), as desired. \( \square \)

6.2. The closure order on nilpotent orbits. In what follows, we will see that nilpotent orbits are profitably studied in the context of the closure order (see 2.4) on the set of adjoint \( G \)-orbits. To help formulate this, recall that a subset \( Q \) of a poset is called a “connected component” if it is maximal with respect to the following property: if \( p, q \in Q \), then there exists a sequence \( r_1, \ldots, r_k \in Q \) with \( r_1 = p, r_k = q \) and for all \( j \in \{1, \ldots, k-1\} \), \( r_j \leq r_{j+1} \) (i.e. \( p \) and \( q \) are “connected” by a sequence of comparisons in \( Q \)). It turns out that the nilpotent orbits form a “connected component” in the poset of adjoint orbits.

**Proposition 6.5.** The nilpotent orbits form a connected component in the poset of adjoint orbits.

Proof. To begin, \( \{0\} \) is clearly a nilpotent orbit and Proposition 6.2(iii) implies that \( \{0\} \leq \Theta \) for all nilpotent orbits \( \Theta \). In other words, all nilpotent orbits are “connected” to \( \{0\} \) in the above-defined sense. In particular, any two nilpotent orbits are connected by a sequence of comparisons with other nilpotent orbits. It now remains only to show maximality, namely that if a nilpotent orbit \( \Theta \) and an adjoint orbit \( \Theta \) satisfy \( \Theta \leq 0 \) or \( 0 \leq \Theta \), then \( \Theta \) is a nilpotent orbit. To this end, suppose \( 0 \leq \Theta \) and \( \Theta \) are nilpotent and adjoint orbits, respectively. If \( \Theta \leq 0 \), then by definition \( \Theta \subseteq \Theta \). Since \( N \) is a closed subvariety of \( g \) (see 3.2) containing \( 0 \), we must have \( \Theta \subseteq N \). Hence \( \Theta \subseteq N \), meaning that \( \Theta \) is a nilpotent orbit. For the other case, assume that \( 0 \leq \Theta \). It follows by definition that \( \Theta \subseteq \Theta \), and therefore also \( \Theta \subseteq \Theta \). Since \( \Theta \subseteq \Theta \) (see Proposition 6.2(iii)), \( \Theta \subseteq \Theta \) and Proposition 6.2 shows that \( \Theta \) is a nilpotent orbit.

**Remark 6.6.** There is no immediate analogue of Proposition 6.5 for semisimple orbits. For one thing, it is possible for \( 0 \leq \Theta \) to hold when \( \Theta \) is a semisimple orbit and \( \Theta \) is a non-semisimple adjoint orbit. Indeed, let \( \Theta \) be any non-semisimple adjoint orbit. Lemma 5.3 implies that there exists a unique semisimple orbit \( \Theta \) satisfying \( \Theta \subseteq \Theta \). By construction, \( \Theta \leq \Theta \).

**Example 6.7.** Let us describe the poset of nilpotent orbits in \( sl_n(C) \). To this end, recall that Example 6.3 uses the partitions of \( n \) to explicitly parametrize the nilpotent \( SL_n(C) \)-orbits. It follows that the closure order on these nilpotent orbits corresponds to a partial order on the partitions of \( n \), which Gerstenhaber [27] Chapt. 1. Thm. 2] and Hesselink [33] Thm. 3.10] showed to coincide with the dominance order on partitions. Two partitions \( \lambda = (\lambda_1, \lambda_2, \ldots, \lambda_k) \) and \( \mu = (\mu_1, \mu_2, \ldots, \mu_l) \) of \( n \) satisfy \( \lambda \leq \mu \) in the dominance order precisely when for all \( p \in \{1, \ldots, n\} \), \( \lambda_1 + \lambda_2 + \ldots + \lambda_p \leq \mu_1 + \mu_2 + \ldots + \mu_p \), where we define \( \lambda_j := 0 \) for \( j > k \) and \( \mu_j := 0 \) for \( j > \ell \).

6.3. The regular nilpotent orbit. Having discussed nilpotent orbits in general, we turn our attention to a few particularly notable orbits. For the first of these, recall that the proof of Theorem 6.4 shows \( N \) to be a fibre of the adjoint quotient. It then follows from Theorem 4.7 that \( N \) contains a unique regular adjoint orbit. This amounts to the existence
of a unique regular nilpotent orbit, which we shall denote by $O_{\text{reg}}$. Alternatively, one can characterize $O_{\text{reg}}$ via the closure order as follows.

**Proposition 6.8.** In the poset of nilpotent orbits with the closure order, $O_{\text{reg}}$ is the unique maximal element.

**Proof.** Let $\emptyset$ be any nilpotent orbit. Since $O_{\text{reg}}$ is dense in $N$ (by Theorem 4.7), we have $\emptyset \subseteq N = \overline{O_{\text{reg}}}$. Hence $\emptyset \leq O_{\text{reg}}$, as desired. □

**Example 6.9.** Recall that Example 6.3 used partitions of $n$ to index nilpotent $\text{SL}_n(\mathbb{C})$-orbits, and Example 6.7 in turn mentioned the correspondence between the dominance order on partitions of $n$ and the closure order on nilpotent $\text{SL}_n(\mathbb{C})$-orbits. Furthermore, one readily sees that the partition $\lambda = (n)$ is the unique maximal element in the dominance order. It follows from Proposition 6.8 that $O_{\text{reg}} \subseteq \text{sl}_n(\mathbb{C})$ is indexed by $\lambda = (n)$, meaning that $O_{\text{reg}}$ is the conjugacy class of the $n \times n$ nilpotent Jordan block.

This last example raises the question of whether, in general, $O_{\text{reg}}$ has any standard representatives. Kostant [42] answered this question in the affirmative, but we will need to recall a few facts about the representation theory of $\text{sl}_2(\mathbb{C})$ before elaborating on his argument. Let $\phi : \text{sl}_2(\mathbb{C}) \to \text{gl}(V)$ be an $\text{sl}_2(\mathbb{C})$-representation, ie. $V$ is a finite-dimensional complex vector space and $\phi$ is a Lie algebra morphism. One knows such a representation to be completely reducible, meaning that

$$V = \bigoplus_{k=1}^{n} V_k$$

for irreducible $\text{sl}_2(\mathbb{C})$-subrepresentations $V_k \subseteq V$. Now let $X, H, Y \in \text{sl}_2(\mathbb{C})$ be the usual generators, as defined in (16). Each subrepresentation $V_k$ decomposes into eigenspaces of $\phi(H)$, which are known to be one-dimensional. The eigenvalues of $\phi(H) : V_k \to V_k$ are integers and form a string as follows: if $\lambda_k$ is the largest eigenvalue, then $\lambda_k \geq 0$ and $-\lambda_k, -\lambda_k + 2, -\lambda_k + 4, \ldots, \lambda_k - 2, \lambda_k$ is a complete list of the eigenvalues. Finally, the last facts we will need are the following decompositions of the kernels of $\phi(X) : V \to V$ and $\phi(H) : V \to V$:

$$(50) \quad \ker(\phi(X)) = \bigoplus_{k=1}^{n} V_k(\lambda_k),$$

$$(51) \quad \ker(\phi(H)) = \bigoplus_{k=1}^{n} V_k(0),$$

where $V_k(\lambda_k)$ and $V_k(0)$ denote the $\lambda_k$ and $0$-eigenspaces of $\phi(H) : V_k \to V_k$, respectively.\footnote{Note that $0$ need not be an eigenvalue, so that $V_k(0) = \{0\}$ may hold.}

**Proposition 6.10.** Recalling the notation used in Example 3.7, the nilpotent element $\xi = \sum_{\alpha \in \Pi} e_\alpha$ belongs to $O_{\text{reg}}$.

**Proof.** This proof will begin with two intermediate claims. For the first, recall that Example 3.7 includes $\xi$ in an explicit $\text{sl}_2(\mathbb{C})$-triple $(\xi, h, \eta)$. We claim that every eigenvalue of $\text{ad}_h : \mathfrak{g} \to \mathfrak{g}$ is an even integer. However, since each summand appearing in the root space
decomposition (7) of \( g \) is \( \text{ad}_h \)-invariant, it will suffice to establish that \( \text{ad}_h \) acts on each summand with only even eigenvalues. Now, since \( \text{ad}_h(x) = 0 \) for all \( x \in \mathfrak{t} \), we see that \( 0 \) is the unique eigenvalue of \( \text{ad}_h : \mathfrak{t} \to \mathfrak{t} \). For the root space summands, suppose \( \beta \in \Delta \). Note that for all \( x \in \mathfrak{g}_\beta \), we have \( \text{ad}_h(x) = \beta(h)x \). To see that the eigenvalue \( \beta(h) \) is an even integer, let us write \( \beta = \sum_{\alpha \in \Pi} c_\alpha \alpha \) for \( c_\alpha \in \mathbb{Z}, \alpha \in \Pi \). Example 3.7 shows that \( \alpha(h) = 2 \) for all \( \alpha \in \Pi \), meaning that \( \beta(h) = 2 \sum_{\alpha \in \Pi} c_\alpha \) is indeed an even integer. Hence every eigenvalue of \( \text{ad}_h : \mathfrak{g} \to \mathfrak{g} \) is an even integer.

Our second claim is that \( C_g(h) \) and \( C_g(\xi) \) have the same dimension. To see this, we restrict the adjoint representation \( \text{ad} : \mathfrak{g} \to \mathfrak{gl}(\mathfrak{g}) \) to a representation of the subalgebra \( \mathfrak{a} := \text{span}(\xi, h, \eta) \cong \mathfrak{sl}_2(\mathbb{C}) \) on \( \mathfrak{g} \). One can now think of \( \mathfrak{g} \) as an \( \mathfrak{sl}_2(\mathbb{C}) \)-representation in which \( X, H, Y \in \mathfrak{sl}_2(\mathbb{C}) \) are identified with \( \xi, h, \eta \in \mathfrak{a} \), respectively. Now, decompose \( \mathfrak{g} \) into irreducible \( \mathfrak{a} \)-subrepresentations,

\[
\mathfrak{g} = \bigoplus_{k=1}^{n} V_k.
\]

Since the eigenvalues of \( \text{ad}_h : \mathfrak{g} \to \mathfrak{g} \) are even integers, the same is necessarily true of the eigenvalues of \( \text{ad}_h \) on each irreducible subrepresentation \( V_k \). The string description of the latter eigenvalues (explained just before this proposition) implies that \( 0 \) occurs as an eigenvalue in each \( V_k \). Since \( V_k(0) \) is then one-dimensional for each \( k \), (51) implies that \( \dim(\ker(\text{ad}_h)) \) equals \( n \), the number of irreducible summands in (52). A similar argument uses (50) to show that \( \dim(\ker(\text{ad}_h)) = n \). Of course, as \( \ker(\text{ad}_h) = C_g(h) \) and \( \ker(\text{ad}_h) = C_g(\xi) \), we have actually shown that \( \dim(C_g(h)) = \dim(C_g(\xi)) \).

We may now give a direct proof of our proposition, which is equivalent to the statement that \( 0(\xi) = 0_{\text{reg}} \). Now, as \( \xi \) is nilpotent and \( 0_{\text{reg}} \) is the unique regular nilpotent orbit, this is equivalent to \( 0(\xi) \) being a regular adjoint orbit. This is in turn equivalent to \( \dim(C_g(\xi)) = \text{rank}(G) \), since \( \dim(0(\xi)) = \dim(G/C_g(\xi)) = \dim(G) - \dim(C_g(\xi)) \). At the same time, we know \( \dim(C_g(\xi)) = \dim(C_g(\xi)) = \dim(C_g(h)) = \dim(C_g(h)) \). Our task is therefore to show that \( \dim(C_g(h)) = \text{rank}(G) \). However, the proof of Corollary 5.8 explains that \( C_g(h) = L_{\Pi(h)} = T \) for our choice of \( h \), so that the \( \dim(C_g(h)) = \dim(T) = \text{rank}(G) \). This completes the proof. \( \square \)

**Remark 6.11.** Kostant found a curious relationship between the decomposition (52) and the topology of \( G \). To formulate it, note that the last two paragraphs in the proof of Proposition 6.10 can be used to show that (52) has exactly \( r := \text{rank}(G) \) irreducible summands. If \( d_1, d_2, \ldots, d_r \) are their respective dimensions, then the Poincaré polynomial of \( G \) factors as follows:

\[
P_G(t) = \prod_{j=1}^{r} (1 + t^{d_j})
\]

(see [42 Cor. 8.7])\(^8\)

\(^8\)Strictly speaking, Kostant's result is that (53) is the Poincaré polynomial of the adjoint group of \( g \). The adjoint group is just the quotient of \( G \) by its (finite) centre, and one can use this fact to show that (53) must also be the Poincaré polynomial of \( G \).
6.4. **The minimal nilpotent orbit.** Having studied $O_{\text{reg}}$ as the unique maximal element in the poset of nilpotent orbits (see Proposition 6.8), it is natural to wonder about an analogous result at the opposite extreme — the existence of a unique minimal nilpotent orbit. However, a first investigation yields underwhelming results. The singleton $\{0\}$ is the unique minimal nilpotent orbit, since Proposition 6.2 implies that $\{0\} \subseteq \mathcal{O}$ for all nilpotent orbits $\mathcal{O}$. It is therefore a natural next step to study the minimal non-zero nilpotent orbits. Interestingly, there turns out to be a unique such orbit when $G$ is simple. At the same time, $G$ being simple implies the existence of a unique $\theta \in \Delta$ with the property of being maximal among all roots in the partial order $\langle \rangle$ (see [57 Thm. 18.9.2]). We then have the following theorem, which is essentially a restatement of Theorem 4.3.3 in [17].

**Theorem 6.12.** If $G$ is simple and $e_\theta \in g_0 \setminus \{0\}$, then $O(e_\theta)$ is the unique minimal element in the poset of non-zero nilpotent orbits.

One denotes the above orbit by $\mathcal{O}_{\text{min}}$ and calls it the *minimal nilpotent orbit*. Note that being minimal in the poset of non-zero nilpotent orbits amounts to the condition $\mathcal{O}_{\text{min}} = \mathcal{O}_{\text{min}} \cup \{0\}$.

**Example 6.13.** Let $G = \text{SL}_n(\mathbb{C})$, a simple group. Recall from Example 6.7 the poset isomorphism between nilpotent $\text{SL}_n(\mathbb{C})$-orbits in the closure order and partitions of $n$ in the dominance order. While $\lambda = (1, 1, \ldots, 1)$ (which corresponds to the orbit $\{0\}$) is clearly the unique minimal partition of $n$, $\mu = (2, 1, 1, \ldots, 1)$ is seen to be minimal once $\mu$ is excluded. It follows that $\mu$ corresponds to $\mathcal{O}_{\text{min}} \subseteq \text{sl}_n(\mathbb{C})$, or equivalently that $\mathcal{O}_{\text{min}}$ is the conjugacy class of a nilpotent Jordan canonical form matrix having a single $2 \times 2$ Jordan block and $0$ for all other entries.

Theorem 6.12 assumes $G$ is simple, so one might legitimately ask whether a unique minimal non-zero nilpotent orbit exists when $G$ is semisimple. The following example shows this to be false in general.

**Example 6.14.** Assume that $G$ is simple, in which case the product $G \times G$ is semisimple but not simple. The latter group has Lie algebra $g \oplus g$, and the adjoint representation $\text{Ad} : G \times G \to \text{GL}(g \oplus g)$ is as follows:

$$\text{Ad}_{(g_1, g_2)}(x_1, x_2) = (\text{Ad}_{g_1}(x_1), \text{Ad}_{g_2}(x_2))$$

for all $(g_1, g_2) \in G \times G$ and $(x_1, x_2) \in g \oplus g$, where (via a slight abuse of notation) $\text{Ad}_{g_1}(x_1)$ and $\text{Ad}_{g_2}(x_2)$ come from the adjoint representation of $G$. Now, let $\theta \in \Delta$ and $e_\theta \in g_0 \setminus \{0\}$ be as discussed above. It follows that the adjoint $G \times G$-orbits of $(e_\theta, 0)$ and $(0, e_\theta)$ are

$$O_{G \times G}(e_\theta, 0) = O_{\text{min}} \times \{0\} \quad \text{and} \quad O_{G \times G}(0, e_\theta) = \{0\} \times O_{\text{min}},$$

respectively, where $O_{\text{min}} \subseteq g$ is the minimal nilpotent $G$-orbit. Taking closures, we have

$$\overline{O}_{G \times G}(e_\theta, 0) = \overline{O}_{\text{min}} \times \{0\} = (O_{\text{min}} \cup \{0\}) \times \{0\} = O_{G \times G}(e_\theta, 0) \cup \{0, 0\}$$

and

$$\overline{O}_{G \times G}(0, e_\theta) = \{0\} \times \overline{O}_{\text{min}} = \{0\} \times (O_{\text{min}} \cup \{0\}) = \{0, 0\} \cup O_{G \times G}(0, e_\theta).$$

These calculations establish two things. Firstly, since the closures of $O_{G \times G}(e_\theta, 0)$ and $O_{G \times G}(0, e_\theta)$ contain $\{0, 0\}$, each orbit is nilpotent (see Proposition 6.2). Secondly, for each orbit, $\{\{0, 0\}\}$ is the unique orbit that is strictly smaller in the closure order. Equivalently,
We conclude that
\[ O_{G \times G}(e_\theta, 0) \text{ and } O_{G \times G}(0, e_\theta) \text{ are minimal among the non-zero nilpotent orbits in the closure order. It is nevertheless clear that } O_{G \times G}(e_\theta, 0) \neq O_{G \times G}(0, e_\theta). \]

6.5. Orbit projectivizations. Recall from Proposition 6.2 that one can characterize nilpotent orbits as those adjoint orbits which are invariant under the dilation action of \( \mathbb{C}^* \) on \( \mathfrak{g} \). We will see that this fact gives rise to a special geometry enjoyed only by the nilpotent orbits. Indeed, given a non-zero nilpotent orbit \( O \subseteq \mathfrak{g} \), we may define its projectivization to be the quotient
\[ \mathbb{P}(O) := O/\mathbb{C}^*. \]
Note that \( \mathbb{P}(O) \) is, by construction, a subset of the projective space \( \mathbb{P}(\mathfrak{g}) = (\mathfrak{g} \setminus \{0\})/\mathbb{C}^* \). The latter is a \( G \)-variety with action map
\[ G \times \mathbb{P}(\mathfrak{g}) \to \mathbb{P}(\mathfrak{g}), \quad (g, [x]) \mapsto [\text{Ad}_g(x)], \quad g \in G, \ [x] \in \mathbb{P}(\mathfrak{g}) \]
(cf. Example 2.9), and it is not difficult to check that \( \mathbb{P}(O) \) is a \( G \)-orbit in \( \mathbb{P}(\mathfrak{g}) \). As such, \( \mathbb{P}(O) \) is a smooth locally closed subvariety of \( \mathbb{P}(\mathfrak{g}) \) (see 2.2). However, \( \mathbb{P}(O) \) is seldom closed.

**Proposition 6.15.** Assume that \( G \) is simple and let \( O \subseteq \mathfrak{g} \) be a non-zero nilpotent orbit. Then \( \mathbb{P}(O) \) is closed in \( \mathbb{P}(\mathfrak{g}) \) if and only if \( O = O_{\text{min}} \).

**Proof.** The nilpotent cone \( N \subseteq \mathfrak{g} \) is \( \mathbb{C}^* \)-invariant, and one may define
\[ \mathbb{P}(N) := (N \setminus \{0\})/\mathbb{C}^*. \]
It is not difficult to see that \( \mathbb{P}(N) \) is a \( G \)-invariant closed subvariety of \( \mathbb{P}(\mathfrak{g}) \) whose \( G \)-orbits are precisely the projectivizations of the non-zero nilpotent orbits. It will therefore be equivalent to prove that \( \mathbb{P}(O_{\text{min}}) \) is the unique closed orbit in \( \mathbb{P}(N) \).

Now, remember that \( \mathbb{P}(O) \) is a union of \( \mathbb{P}(O) \) and the \( G \)-orbits lying below \( \mathbb{P}(O) \) in the closure order. Showing \( \mathbb{P}(O_{\text{min}}) \) to be the unique closed orbit is therefore equivalent to showing it to be the unique minimal orbit in \( \mathbb{P}(N) \). We shall do the latter.

Let \( O \subseteq \mathfrak{g} \) be any non-zero nilpotent orbit. Since \( O_{\text{min}} \) is the unique minimal non-zero nilpotent orbit in the closure order, it must be true that \( O_{\text{min}} \subseteq \overline{O} \setminus \{0\} \). Also, because \( N \) is closed in \( \mathfrak{g} \) and contains \( O, \overline{O} \setminus \{0\} \) is the closure of \( O \) in \( N \setminus \{0\} \). The continuity of the quotient map \( \pi : N \setminus \{0\} \to \mathbb{P}(N) \) therefore implies \( \pi(\overline{O} \setminus \{0\}) \subseteq \overline{\pi(O)} \), and we have
\[ \mathbb{P}(O_{\text{min}}) = \pi(O_{\text{min}}) \subseteq \pi(\overline{O} \setminus \{0\}) \subseteq \overline{\pi(O)} = \overline{\mathbb{P}(O)}. \]
In other words, \( \mathbb{P}(O_{\text{min}}) \) belongs to the closure of \( \mathbb{P}(O) \) for all non-zero nilpotent orbits \( O \). We conclude that \( \mathbb{P}(O_{\text{min}}) \) is the unique minimal orbit in \( \mathbb{P}(N) \), as desired. \( \square \)

Seeking to build on Proposition 6.15, we will assume \( G \) to be simple for the duration of 6.5

**Remark 6.16.** Recall that the image of a projective variety under a morphism is necessarily closed. If \( \mathbb{P}(O) \) is projective, we may take this morphism to be the inclusion \( \mathbb{P}(O) \hookrightarrow \mathbb{P}(\mathfrak{g}) \) and conclude that \( \mathbb{P}(O) \) is closed in \( \mathbb{P}(\mathfrak{g}) \). Conversely, if \( \mathbb{P}(O) \) is closed in \( \mathbb{P}(\mathfrak{g}) \), then the former is necessarily projective. These last two sentences explain that \( \mathbb{P}(O) \) is projective if and only if it is closed in \( \mathbb{P}(\mathfrak{g}) \), which by Proposition 6.15 is equivalent to \( O = O_{\text{min}} \). In particular, \( \mathbb{P}(O) \) is generally not projective.

\(^9\)Strictly speaking, this will only show \( \mathbb{P}(O) \) to be closed if and only if \( \mathbb{P}(O) = \mathbb{P}(O_{\text{min}}) \). We leave it as an exercise to check that \( \mathbb{P}(O) = \mathbb{P}(O_{\text{min}}) \) if and only if \( O = O_{\text{min}} \).
While Proposition 6.15 is an important first step in understanding \( \mathbb{P}(O_{\min}) \), one can say a great deal more. Indeed, as \( \mathbb{P}(O_{\min}) \) is a G-orbit, it must be G-equivariantly isomorphic to \( G/P \) for some closed subgroup \( P \subseteq G \). Furthermore, since \( \mathbb{P}(O_{\min}) \) is projective, \( P \) is necessarily a parabolic subgroup of \( G \) (see [57, Cor. 28.1.4]). This subgroup contains a conjugate of \( B \), meaning that \( P \) is conjugate to a standard parabolic subgroup \( P_S \) (as defined in \([3.1]\)). One can use this to verify that \( G/P \cong G/P_S \), so that \( \mathbb{P}(O_{\min}) \) and \( G/P_S \) are G-equivariantly isomorphic for some subset \( S \subseteq \Pi \). The following proposition shows that one can take \( S \) to be

\[
\Pi(\theta) := \{ \alpha \in \Pi : \langle \alpha, \theta \rangle = 0 \},
\]

the set of simple roots that are orthogonal to the maximal root \( \theta \).

**Proposition 6.17.** If \( G \) is simple, then there is a G-variety isomorphism \( G/P_{\Pi(\theta)} \cong \mathbb{P}(O_{\min}) \).

**Proof.** Fix \( e_\theta \in g_\theta \setminus \{0\} \) and recall that \( e_\theta \in O_{\min} \) (see Theorem 6.12). It follows that \( [e_\theta] \in \mathbb{P}(O_{\min}) \), so that \( \mathbb{P}(O_{\min}) \) is the G-orbit of \( [e_\theta] \) in \( \mathbb{P}(g) \). We claim that \( C_G([e_\theta]) = P_{\Pi(\theta)} \), which together with the orbit-stabilizer isomorphism (3) will prove the proposition.

Since \( G \) is simple, its adjoint representation is irreducible (see [37, Sect. 0.11]) and \( \theta \) is the maximal weight of this representation. It follows that \( \text{Ad}(b)(e_\theta) \) is a non-zero multiple of \( e_\theta \) for each \( b \in B \) (see [36, Sect. 31.3]). This shows that \( B \subseteq C_G([e_\theta]) \), meaning that \( C_G([e_\theta]) \) is a standard parabolic subgroup of \( G \). In other words, \( C_G([e_\theta]) = P_S \) for some subset \( S \subseteq \Pi \), and we must show \( S = \Pi(\theta) \). Now by the correspondence between subsets of \( \Pi \) and standard parabolic subgroups (see \([3.1]\)), \( S \) is the set of simple roots \( \alpha \) for which \( g_\alpha \) belongs to \( C_\theta([e_\theta]) \), the Lie algebra of \( C_G([e_\theta]) \). One can show that \( C_\theta([e_\theta]) = \{ \xi \in g : [\xi, g_\theta] \subseteq g_\theta \} \), so that \( \alpha \in \Pi \) belongs to \( S \) if and only if \( [g_\alpha, g_\theta] \subseteq g_\theta \). Furthermore, as \( [g_\alpha, g_\theta] \cap g_\theta = \{0\} \), it follows that \( \alpha \) belongs to \( S \) if and only if \( [g_\alpha, g_\theta] = \{0\} \). Hence, showing \( S = \Pi(\theta) \) amounts to proving that \( \alpha \in \Pi \) satisfies \( [g_\alpha, g_\theta] = \{0\} \) if and only if \( \langle \alpha, \theta \rangle = 0 \).

Assume that \( [g_\alpha, g_\theta] = \{0\} \). Since \( \theta \) is the maximal root, \( \alpha + \theta \) is not a root and we have \( [g_\alpha, g_\theta] \subseteq g_{\alpha+\theta} = \{0\} \). Applying the Jacobi identity, we see that

\[
[g_\alpha, g_\theta] = \{0\}. \tag{54}
\]

Letting \( h_\alpha \in [g_\alpha, g_\alpha] \) be the coroot associated with \( \alpha \), (54) gives

\[
0 = [h_\alpha, e_\theta] \theta = \theta(h_\alpha)e_\theta = 2 \frac{\langle \alpha, \theta \rangle}{\langle \alpha, \alpha \rangle} e_\theta.
\]

It follows that \( \langle \alpha, \theta \rangle = 0 \).

Conversely, assume that \( \langle \alpha, \theta \rangle = 0 \). If \( [g_\alpha, g_\theta] \neq \{0\} \), then \( g_{\alpha-\theta} \neq \{0\} \) and \( \theta - \alpha \) is a root. Since the set of roots is invariant under the action of \( W \) on \( t^* \), \( s_\alpha \cdot (\theta - \alpha) \) is also a root. However,

\[
s_\alpha \cdot (\theta - \alpha) = s_\alpha \cdot \theta - s_\alpha \cdot \alpha = \theta - 2 \frac{\langle \alpha, \theta \rangle}{\langle \alpha, \alpha \rangle} \alpha + \alpha = \theta + \alpha,
\]

and this contradicts the maximality of \( \theta \). We conclude that \( [g_\alpha, g_\theta] = \{0\} \). \( \square \)

**Example 6.18.** One can use Proposition 6.17 to give a more classical description of \( \mathbb{P}(O_{\min}) \) when \( G = \text{SL}_n(\mathbb{C}) \). To do this, recall the \( \text{SL}_n(\mathbb{C}) \)-specific discussion of the maximal torus, Borel subgroup, roots, simple roots, etc. given in Example 3.1. It turns out that \( \theta = t_1 - t_n \) is the maximal root, which by the Killing form description (15) implies that
However, recall from 4.5 that one can identify coadjoint orbits with adjoint orbits. In other words, a matrix \( A \in \text{SL}_n(\mathbb{C}) \) belongs to \( P_{\Pi(\theta)} \) if and only if it is block upper-triangular with blocks of dimensions \( 1 \times 1, (n-2) \times (n-2), \) and \( 1 \times 1 \) along the diagonal (read from top to bottom).

Now, recall that Example 2.15 computed the \( \text{GL}_n(\mathbb{C}) \)-stabilizer of the flag \( V_\bullet \in \text{Flag}(d_\bullet; \mathbb{C}^n) \). Note that the \( \text{SL}_n(\mathbb{C}) \)-stabilizer of \( V_\bullet \) is obtained by intersecting \( \text{SL}_n(\mathbb{C}) \) with the \( \text{GL}_n(\mathbb{C}) \)-stabilizer. Furthermore, when \( d_\bullet = (1, n-1) \), it is not difficult to see that \( C_{\text{SL}_n(\mathbb{C})}(V_\bullet) \) coincides with (55). The action of \( \text{SL}_n(\mathbb{C}) \) on \( \text{Flag}(1, n-1; \mathbb{C}^n) \) is transitive, so that we have \( \text{Flag}(1, n-1; \mathbb{C}^n) \equiv \text{SL}_n(\mathbb{C})/C_{\text{SL}_n(\mathbb{C})}(V_\bullet) = \text{SL}_n(\mathbb{C})/P_{\Pi(\theta)}. \) Proposition (6.17) identifies \( \text{SL}_n(\mathbb{C})/P_{\Pi(\theta)} \) with \( \mathbb{P}(\mathcal{O}_{\min}) \), meaning that we have an \( \text{SL}_n(\mathbb{C}) \)-variety isomorphism

\[
\mathbb{P}(\mathcal{O}_{\min}) \cong \text{Flag}(1, n-1; \mathbb{C}^n).
\]

**Remark 6.19.** Using similar ideas, one can obtain classical descriptions of \( \mathbb{P}(\mathcal{O}_{\min}) \) in other Lie types. In type \( \text{D}_n \), for instance, \( \mathbb{P}(\mathcal{O}_{\min}) \) identifies with the Grassmannian of isotropic 2-dimensional subspaces in \( \mathbb{C}^{2n} \) (see [18, Sect. 4.2]).

On a somewhat different note, \( \mathbb{P}(\mathcal{O}_{\min}) \) turns out to feature prominently in quaternionic-Kähler geometry (see [56] for a brief introduction). To develop this point, let \( X \) be a complex manifold and \( E \) a holomorphic subbundle of \( TX \). One then has a short exact sequence of holomorphic bundles on \( X \),

\[
0 \rightarrow E \rightarrow TX \overset{\theta}{\rightarrow} F \rightarrow 0,
\]

where \( F := TX/E \) and \( \theta \) is the quotient map. Let \( \mathcal{E} \) and \( \mathcal{F} \) denote the sheaves of sections of \( E \) and \( F \), respectively, and consider the following pairing:

\[
(\mathcal{E} \otimes \mathcal{E}) \rightarrow \mathcal{F}, \quad (s_1, s_2) \mapsto \theta([s_1, s_2]).
\]

One calls \( E \) a complex contact structure if \( E \) has co-rank one in \( TX \) and the pairing (56) is non-degenerate (on both local and global sections of \( E \)). Once endowed with a complex contact structure, \( X \) is called a complex contact manifold.

Now, let \( \mathfrak{o} \subset \mathfrak{q} \) be a non-zero nilpotent orbit and recall the canonical symplectic form \( \omega_0 \in \Omega^2(\mathfrak{o}) \) defined in (25). One can use \( \omega_0 \) to induce a canonical complex contact structure on \( \mathbb{P}(\mathfrak{q}) \) (see [5] Prop. 2.2, Rmk. 2.3, Sect. 2.4[1]), so that \( \mathbb{P}(\mathfrak{q}) \) is a complex contact manifold. In particular, \( \mathbb{P}(\mathcal{O}_{\min}) \) belongs to the class of Fano contact manifolds (see [48] Def. 1.3, Def. 2.5]), which are of interest to quaternionic-Kähler geometers (see [48] Sect. 1). Moreover, it is in the quaternionic-Kähler context that LeBrun and Salamon conjectured the following classification of Fano contact manifolds: each is isomorphic, as a complex contact manifold, to the projectivization of the minimal nilpotent orbit of a simple algebraic group. This conjecture is known to be true in a number of cases (see [5]), and counter-examples have not yet been found.

---

Note that some of these are phrased in the language of coadjoint orbits, rather than adjoint orbits. However, recall from [4.5] that one can identify coadjoint orbits with adjoint orbits.

---

Note that some of these are phrased in the language of coadjoint orbits, rather than adjoint orbits.
Remark 6.20. When $P(O_{\min})$ is described in classical terms, as in Example 6.18, one should expect a similarly classical description of its complex contact structure. Such a description is given in [18, Sect. 4.2] in Lie type $D_n$, when $P(O_{\min})$ is viewed as the Grassmannian of isotropic 2-dimensional subspaces of $\mathbb{C}^{2n}$.

6.6. Orbit closures and singularities. It turns out that nilpotent orbit closures have been studied extensively in the literature, both intrinsically and as parts of broader research programs. We now briefly survey some of this literature, giving references where necessary in order to avoid long digressions.

Recall that the closure of $O_{\text{reg}}$ is the nilpotent cone $N$. This is a singular variety and there exists a canonical resolution of singularities $\mu : T^*(G/B) \to N$ called the Springer resolution (see [16, Def. 3.2.4]). While fundamental to the study of singularities in $N$, $\mu$ also plays a significant role in adjacent subjects. In geometric representation theory, one constructs a representation of the Weyl group on the Borel-Moore homology of each fibre of $\mu$ (see [16, Sect. 3.4–3.6]). In symplectic geometry, $T^*(G/B)$ and $O_{\text{reg}}$ have canonical symplectic forms (see [16 Sect. 1.1] for the former and [4.5] for the latter) and $\mu$ is an example of a symplectic resolution (see [23 Sect. 1.3] for a definition, and all of [23] for an introduction to the subject). This turns out to be an instance of a more general occurrence: for certain nilpotent orbits $O \subseteq g$, one can find a parabolic subgroup $P \subseteq G$ and a symplectic resolution $T^*(G/P) \to O$ (see [23 Sect. 5.1]). These nilpotent orbit closures thereby give examples of symplectic singularities (see [6, Def. 1.1]), which have received a great deal of recent attention (see [6,24,28,39]).

In addition to the above, nilpotent orbits closures are sometimes studied through their intersections with certain affine-linear subsets of $g$, often called Slodowy slices (see [16, Prop. 3.7.15]). This study was initiated by the works of Brieskorn [13] and Slodowy [52], which show the intersection of $O_{\text{reg}} = N$ with a particular Slodowy slice to contain a Kleinian surface singularity when $g$ is of type ADE (see [52, Sect. 6.4] for further details). This result is interesting in many contexts, and in particular plays a role in Kronheimer’s study of nilpotent orbits in hyperkähler geometry (see [47, Prop. 2(a), Prop. 2(b)]).
