Motivation

Problem  \( \text{LTL} \Rightarrow \text{deterministic } \omega - \text{automata} \)

Background  1. Synthesis of reactive modules for LTL specifications[PR88].
2. Model checking Markov decision processes[BK08].

Previous approach  1. \( \text{LTL} \Rightarrow \text{non-deterministic } \text{B"uchi} \) automaton(NBW) and then NBW \( \Rightarrow \) deterministic Rabin automata by Safra’s construction[Saf88]

disadvantage  Safra’s construction is difficult to handle algorithmically due to its “messy” state space

Definition 1 (LTL Syntax). The formulae of the \((F,G)\)-fragment of linear temporal logic are given by the following syntax:

\[
\varphi ::= a \mid \neg a \mid \varphi \land \varphi \mid \varphi \lor \varphi \mid F\varphi \mid G\varphi
\]

where \(a\) ranges over a finite fixed set \(Ap\) of atomic propositions.

We use the standard abbreviations \(tt := a \lor \neg a\), \(ff := a \land \neg a\). We only have negations of atomic propositions, as negations can be pushed inside due to the equivalence of \(F\varphi\) and \(\neg G\neg \varphi\).

Construction of state space

- Given a LTL $\varphi$, output a deterministic automation
- clue: $\cup()$
  - $\text{closure}(\varphi) = C(\varphi) := Ap \cup \{\neg a | a \in Ap\} \cup X\top$.
  - $F$ and $G$ is the set of all subformulae of the form $F\varphi$ and $G\varphi$
  - $T := F \cup G$
  - $X\psi := \{X\psi | \psi \in \Psi\}$
- $\text{states}(\varphi)$ is the set of $2^{\mid \varphi \mid}$.
Construction of state space

- \( A(\varphi) = (Q, i, \delta) \) to be a deterministic finite automaton over \( \Sigma = 2^{Ap} \) given by
  - the set of states \( Q = \{i\} \cup (\text{states}(\varphi) \times 2^{Ap}) \)
  - the initial state \( i \)
  - the transition function
    - \( \delta = \{(i, \alpha, < \cup(\varphi), \alpha >) | \alpha \in \Sigma\} \cup \{(< \psi, \alpha >, \beta, < \text{succ}(\psi, \alpha), \beta >) | < \psi, \alpha > \in Q, \beta \in \Sigma\} \)
    - \( \text{succ}(\psi, \alpha) = \cup(\text{next}(\psi[\alpha \mapsto tt, Ap \setminus \alpha \mapsto ff])) \)
    - \( \text{next}(\psi) \) removes X’s from \( \varphi \)
  - \( \text{states}(\varphi) \) is the set of \( 2^{2|\varphi|} \).
  - Key point: store one-step history.
Construction of state space

Example $\varphi = Fa$
Construction of state space

- Is one-step history very important?
- Example $\varphi = GF(a \land Fb)$
  - $\mathcal{U}(\varphi) = XGF(a \land Fb) \land (XF(a \land Fb) \lor (a \land (b \lor XFb)))$
  - after reading $a$
  - $GF(a \land Fb) \land (F(a \land Fb) \lor Fb)$
  - after reading $b$ and $\emptyset$
  - $GF(a \land Fb) \land (F(a \land Fb))$
  - infinitely required ($GF(a \land Fb)$)
  - thus, ($\{a\}\{b\})^\omega$ and ($\{a\}\emptyset)^\omega$ are equal.

- Solution:
  - one-step history.

(F,G)-fragment of LTL

报告人：谢淼
Muller Accepting Condition

The set of all states visited infinitely often must be an element of the acceptance set.
Until now, we have a formula \( \varphi \) and its corresponding automaton \( A(\varphi) = (Q, i, \delta) \).

Consider a formula \( \chi \) as a Boolean Function over elements of \( C(\varphi) \).

For sets \( T, F \subseteq C(\varphi) \), let \([ T \mapsto tt, F \mapsto ff]\) denote the formula where \( tt \) is substituted for elements of \( T \), and \( ff \) for \( F \).

\[ I \models_\alpha \chi : \chi[\alpha \cup I \mapsto tt, Ap\setminus\alpha \mapsto ff] \text{ is equivalent to } tt, \text{ where } I \subseteq T \]
Muller acceptance

A set $M \subseteq Q$ is Muller accepting for a set $I \subseteq \mathbb{T}$ if the following is satisfied:

1. for each $(\chi, \alpha) \in M$, we have $XI \models_\alpha \chi$,
2. for each $F\psi \in I$ there is $(\chi, \alpha) \in M$ with $I \models_\alpha \psi$,
3. for each $G\psi \in I$ and for each $(\chi, \alpha) \in M$ we have $I \models_\alpha \psi$.

A set $F \subseteq Q$ is Muller accepting (for $\varphi$) if it is Muller accepting for some $I \subseteq \mathbb{T}$. 
Method

Example $\varphi = F(Ga \lor Gb)$

Method
Correctness of sound and complete
Correctness of sound and complete

- Theorem

Let $\varphi$ be a formula and $w$ a word. Then $w$ is accepted by the deterministic automaton $A(\varphi)$ with the Muller condition $M(\varphi)$ if and only if $w \models \varphi$. 

\[ \text{Deterministic Automaton for the (F,G)-fragment of LTL} \]

\[ \text{Muller accepting condition} \]

\[ \text{Rabin accepting condition} \]

\[ \text{Complexity} \]

\[ \text{Experiments and Conclusion} \]
Correctness of sound and complete

- Proposition Local finitary correctness
- Let \( w \) be a word and \( A(\varphi)(w) = i(\chi_0, \alpha_0)(\chi_1, \alpha_1) \ldots \) the corresponding run. Then for all \( n \in \mathbb{N} \), we have \( w \models \varphi \) if and only if \( w_n \models \chi_n \)
- Proof: The one-step unfold produces a temporally equivalent (w.r.t. LTL satisfaction) formula. The unfold is a Boolean function over atomic propositions and elements of \( XT \). Therefore, this unfold is satisfied if and only if the next state satisfied next(\( \varphi \)) where \( \varphi \) is the result of partial application of the Boolean function to the currently read letter of the word. We conclude by induction. Comments: each occurrence of satisfaction of \( F \) must happen in limit time.
Correctness of sound and complete

- Completeness
- If $w \models \varphi$ then $\text{Inf}(A(\varphi)(w))$ is a Muller accepting set.

Proof:

1. Let us show that $M := \text{Inf}(A(\varphi)(w))$ is a Muller accepting for $I := \{ \psi \in F | w \models G\psi \} \cup \{ \psi \in G | w \models F\psi \}$

2. Condition 1. Let $(\chi, \beta) \in M$. Since $w \models \varphi$ by Proposition Local finitary correctness $w_i \models \chi$ whenever we enter $(\chi, \alpha)$ after reading $w^i$, which happens for infinitely many $i \in \mathbb{N}$. Hence we have a recurring set $I_{\chi, \alpha}$ modelling $\chi$. Since $I_{\chi, \alpha} \models_{\alpha} \chi$ we get also $I \models_{\alpha} \chi$ by $I_{\chi, \alpha} \subseteq I$. 

(F,G)-fragment of LTL

报告人：谢淼
Condition 2. Let $F\psi \in I$, then $w \models GF\psi$. Since there are finitely many states, there is $(\chi, \alpha) \in M$ for which after infinitely many entrances by $w^i$ it holds $w_i \models \psi$ by Proposition 9, hence we have a recurring set $I_{\chi,\alpha}$ modelling $\psi$ and conclude as above.

Condition 3. Let $G\psi \in I$, then $w \models FG\psi$. Hence for every $(\chi, \alpha) \in M$ infinitely many $w^i$ leading to $(\chi, \alpha)$ satisfy $w_i \models \psi$ by Proposition 9, hence we have a recurring set $I_{\chi,\alpha}$ modelling $\psi$ and conclude as above. $\square$
Lemma 11. Let ρ be a run. If Inf(ρ) is Muller accepting for I then Ap(ρ) ⊨ Gψ for each ψ ∈ I ∩ F and Ap(ρ) ⊨ Fψ for each ψ ∈ I ∩ G.

Proof. Denote w = Ap(ρ). Let us first assume ψ ∈ I ∩ F and wj ⊭ ψ for all j ≥ i ∈ N. Since ψ ∈ I ∩ F, for infinitely many j, ρ passes through some (χ, α) ∈ Inf(ρ) for which I |=α ψ. Hence, there is ψ₁ ∈ I which is a subformula of ψ such that for infinitely many i, wi ⊭ ψ₁. If ψ₁ ∈ F, we proceed as above; similarly for ψ₁ ∈ G. Since we always get a smaller subformula, at some point we obtain either ψₙ = Fβ or ψₙ = Gβ with β a Boolean combination over Ap and we get a contradiction with the second or the third point of Definition 7, respectively.

In other words, if we have a Muller accepting set for I then all elements of I hold true in wi for almost all i.
Proposition 12 (Soundness). If \( \text{Inf}(A(\varphi)(w)) \) is a Muller accepting set then \( w \models \varphi \).

Proof. Let \( M := \text{Inf}(A(\varphi)(w)) \) be a Muller accepting set for some \( I \). There is \( i \in \mathbb{N} \) such that after reading \( w^i \) we come to \((\chi, \alpha)\) and stay in \( \text{Inf}(A(\varphi)(w)) \) from now on and, moreover, \( w^i \models \psi \) for all \( \psi \in I \) by Lemma 11. For a contradiction, let \( w \not\models \varphi \). By Proposition 9 we thus get \( w^i \not\models \chi \). By the first condition of Definition 7, we get \( I \models_{\alpha} \chi \). Therefore, there is \( \psi \in I \) such that \( w^i \not\models \psi \), a contradiction. \( \square \)

Rabin accepting condition

**Definition 14 (Generalized Rabin Automaton).** A generalized Rabin automaton is a (deterministic) \( \omega \)-automaton \( A = (Q, i, \delta) \) over some alphabet \( \Sigma \), where \( Q \) is a set of states, \( i \) is the initial state, \( \delta : Q \times \Sigma \to Q \) is a transition function, together with a generalized Rabin condition \( GR \in B^+(2^Q \times 2^Q) \). A run \( \rho \) of \( A \) is accepting if \( \text{Inf}(\rho) \models GR \), which is defined inductively as follows:

\[
\begin{align*}
\text{Inf}(\rho) \models \varphi & \land \psi \iff \text{Inf}(\rho) \models \varphi \text{ and } \text{Inf}(\rho) \models \psi \\
\text{Inf}(\rho) \models \varphi & \lor \psi \iff \text{Inf}(\rho) \models \varphi \text{ or } \text{Inf}(\rho) \models \psi \\
\text{Inf}(\rho) \models (F, I) & \iff F \cap \text{Inf}(\rho) = \emptyset \text{ and } I \cap \text{Inf}(\rho) \neq \emptyset
\end{align*}
\]
Rabin accepting condition

- How to use Rabin Condition by an example
  \[ \varphi = FGa \lor GFb \]
  \[ \mathcal{U}(\varphi) = XFGa \lor (XGa \land a) \lor (XGFb \land (XFb \lor b)) \]
- sub-element: Ga, FGa, GFb, Fb
- require: visit states with \( \neg a \) only finitely often, visit \( b \) infinitely often.
- Rabin condition: \( (\{q|q \models \neg a, Q\} \lor (\emptyset, \{q|q \models b\})) \)
Rabin accepting condition

Definition 15 (Generalized Rabin Acceptance). Let $\varphi$ be a formula. The generalized Rabin condition $GR(\varphi)$ is

$$
\bigvee_{I \subseteq T} \left( \left\{ (\chi, \alpha) \mid I \not\models_\alpha \chi \land \bigwedge_{\psi \in I} \psi \right\} \cup \{Q\} \land \bigwedge_{\omega \in I} \left( \emptyset, \{(\chi, \alpha) \mid I \models_\alpha \omega\} \right) \right)
$$

By the argumentation above, we get the equivalence of the Muller and the generalized Rabin conditions for $\varphi$ and thus the following.

Proposition 16. Let $\varphi$ be a formula and $w$ a word. Then $w$ is accepted by the deterministic automaton $A(\varphi)$ with the generalized Rabin condition $GR(\varphi)$ if and only if $w \models \varphi$. 
How to obtain a Rabin automaton from $A(\varphi)$ and the generalized Rabin condition $GR(\varphi)$

For a fixed $I$, the whole conjunction of Definition 15 corresponds to the intersection of automata with different Rabin conditions.

$$(G, Q) \land \bigwedge_{f \in F : \equiv I \subseteq F} (\emptyset, F_f)$$

- “counting construction approach” that $Q' = Q \times (1, \ldots, n)$
- $(G \times F, F_{\bar{f}} \times \{\bar{f}\})$ for an arbitrary fixed $\bar{f} \in F$
Rabin accepting condition

- State Space
- \( \varphi = (FGa \lor GFb) \land (FGc \lor GFd) \land (FGe \lor GFf) \)
- \( FG \) or \( GF \) proposition
- state space of \( A \) is \( \{i\} \cup 2\{abcdef\} \), the size is \( 1 + 2^6 \)
- \((\neg a, Q) \lor (\emptyset, b)) \land ((\neg c, Q) \lor (\emptyset, d)) \land ((\neg e, Q) \lor (\emptyset, f)) \)
- right of the pairs: \( tt, b, d, f, b \land d, b \land f, d \land f, b \land d \land f \)
- \( 2 \times 2 \times 2 \times 3 = 24 \)
- state space is of the size of \( 24 \times 1 \times (1 + 2^6) = 1560 \)

   - Conclusion and Future Works
Experimental Results

- **Aim**: Compare the size of produced automaton by our method with the Rabin automaton produced by ltl2dstar.
- **Method**: Ltl2dstar firstly calls an external translator from LTL to non-deterministic Büchi automata by LTL2BA. Then it performs Safra’s determinization.
- Ltl2dstar implements several optimizations of Safra’s construction.
- our implementation does not perform any ad hoc optimization, since we want to evaluate whether the basic idea of the Safraless construction is already competitive.
Experimental Results

- Database: BEEM (BEEnchmarks for Explicit Model checkers) [Pel07] and formulae from [SB00] which tests Ltl2dstar.

- Record attributes:
  1. $|states(\varphi)|$, the number of the first component.
  2. Muller/GR, the number of states of the Muller or generalized Rabin automata follows.
  3. $\mathcal{G}R$-factor, the complexity of generalized Rabin condition.
  4. Rabin, the number of copies of the state space that are created to obtain an equivalent Rabin automaton
  5. Ltl2dstar, the size of the state space of the Rabin automaton generated by Ltl2dstar using LTL2BA.
Table 1. Experimental comparison to ltl2dstar on formulae of [Pel07], [SB00], fairness constraints and some other examples of formulae of the “infinitary” fragment

| Formula                        | states | Muller/GR | GR-factor | Rabin | ltl2dstar |

Experimental Results

- Advantage: for “infinitary” fragment, fairness constraints, Drawback: for “finitary” behavior.
- Reason: The problem is that some states such as
  \(< a \lor XFa, \{a\}>\) are only “passed through” and are equivalent to some of their successors, here \(< tt, \{a\}>\).
- Overcome: perform the following collapse:
  - For two states, \((\chi, \alpha), (\chi', \alpha)\) satisfy that
    \(\chi[\alpha \mapsto tt, Ap \backslash \alpha \mapsto ff]\) is propositionally equivalent to
    \(\chi'[\alpha \mapsto tt, Ap \backslash \alpha \mapsto ff]\), collapse.
- result: the size as the one produced by ltl2dstar.
  \((Fa \land Fb)\)
Experimental Results

Example $\varphi = Fa$

5. **Complexity**

6. **Experiments and Conclusion**
   - Experimental Results
   - Conclusion and Future Works
Conclusion

1. show a direct translation of the LTL fragment with operators F and G to deterministic automata.
2. First of all, in our opinion it is a lot simpler than the determinization and its various non-trivial optimizations.
3. the state space has a clear logical structure.
4. the state space is not much bigger even when compared to already optimized determinization. Very often it is considerably smaller, especially for the “infinitary” formulae; in particular, for fairness conditions.
5. given a very compact deterministic w-automaton with a small and in our opinion reasonably simple generalized Rabin acceptance condition.
Future works

1. Extend to the (X,F,G)-fragment and even to the whole LTL. (may have a n-step look-ahead, for instance, \(GF(a \land Xb))\)
2. There is space for further performance improvements in this new approach by optimizations
