We prove that there are tripartite quantum states (constructed from random unitaries) that can lead to arbitrarily large violations of Bell inequalities for dichotomic observables. As a consequence these states can withstand an arbitrary amount of white noise before they admit a description within a local hidden variable model. This is in sharp contrast with the bipartite case, where all violations are bounded by Grothendieck’s constant. We will discuss the possibility of determining the Hilbert space dimension from the obtained violation and comment on implications for communication complexity theory. Moreover, we show that the violation obtained from generalized GHZ states is always bounded so that, in contrast to many other contexts, GHZ states do in this case not lead to extremal quantum correlations. In order to derive all these physical consequences, we will have to obtain new mathematical results in the theories of operator spaces and tensor norms. In particular, we will prove the existence of bounded but not completely bounded trilinear forms from commutative C*-algebras.

I. INTRODUCTION

Bell inequalities characterize the boundary of correlations achievable within classical probability theory under the assumption that Nature is local [72]. Originally, Bell [10] proposed the inequalities, which now bear his name, in order to put the intuition of Einstein, Podolski and Rosen [27] on logically firm grounds, thus proving that an apparently metaphysical dispute could be resolved experimentally. Nowadays, the verification of the violation of Bell inequalities has become experimental routine [8, 58, 70] (albeit there is a remaining desire for a unified loophole-free test). On the theoretical side—in the realm of quantum information theory—they became indispensable tools for understanding entanglement [6, 64, 68, 73] and its applications in cryptography [2, 3, 4, 28, 62] and communication complexity [13]. In fact, the insight gained from the violation of Bell inequalities enables us even to consider theories beyond quantum mechanics [45, 74] and allows to replace quantum mechanics by the violation of some Bell inequality in the set of trusted assumptions for secure cryptographic protocols [2, 8, 10, 60, 62].

Most of our present knowledge on Bell inequalities and their violation within quantum mechanics is based on the paradigmatic Clauser-Horne-Shimony-Holt (CHSH) inequality [19]. It bounds the correlations obtained in a setup where two observers can measure two dichotomic observables each. In fact, it is the only non-trivial constraint on the polytope of classically reachable correlations in this case [29]. If we allow for more observables (measurement settings) per site or more sites (parties) the picture is much less complete. Whereas for two dichotomic observables per site the complete set of multipartite ‘full-correlation inequalities’ and their maximal violations within quantum mechanics is still known [75, 76], the case of more than two settings is, despite considerable effort [39, 50, 77], largely unexplored.

One reason is, naturally, that finding all possible Bell inequalities is a computationally hard task [1, 57] and that in addition the violating quantum systems become vastly more complicated as the number of sites and dimensions increases. Another reason could be the lack of appropriate mathematics to tackle the problem. Thus far, researchers have primarily used algebraic and combinatorial techniques.

In this work, following the lines already implicit in [66], we will relate tripartite Bell inequalities with two powerful theories of mathematical analysis: operator spaces, and tensor norms. We will give new mathematical results inside these theories and show how to apply them to provide a deeper insight into the understanding of Bell inequalities, by proving some new and intriguing results on their maximal quantum violation. It is interesting to note here that operator spaces have recently also led to other applications in Quantum Information [24].

We will start by outlining the main result and some of its implications within quantum information theory. Sec. III will then recall basic notions from the theory of operator spaces and tensor norms and bridge between the language
of Bell inequalities and the mathematical theories. In Sec. IV we will prove that the violation remains bounded for GHZ states. Finally, Sec. V provides the proof for the main theorem.

II. MAIN RESULT AND IMPLICATIONS

We begin by specifying the framework. For the convenience of the non-specialist reader we will give first a brief introduction to Bell Inequalities. For further information we refer the reader to [72].

Bell inequalities can be dated back to the famous critic of Quantum Mechanics due to Einstein, Podolski and Rosen [27]. This critic was made under their belief that on a fundamental level Nature was described by a local hidden variable (LHV) model, i.e., that it is classical (realistic or deterministic) and local (or non-signaling). The latter essentially means that no information can travel faster than a maximal speed (e.g. of light) which implies in particular that the probability distribution for the outcomes of some experiment made by Alice cannot depend on what other (spatially separated) physicist Bob does in his lab. Otherwise, by choosing one or the other experiment, Bob could influence instantly Alice’s results and hence transmit information at any speed. On the other hand, saying that Nature is classical or deterministic means that the randomness in the outcomes that is observed in the experiments comes from our ignorance of Nature, instead of being an intrinsic property of it (as Quantum Mechanics postulates). That is, Nature can stay in different configurations with some probability $p(s)$ ($s$ is usually called a hidden variable). But once it is in a fixed configuration $s$, then any experiment has deterministic outputs. We note that there are non-deterministic LHV models as well, but they can all be cast into deterministic models [72]. Let us formalize this a bit more.

Consider correlation experiments where each of $N$ spatially separated observers (Alice, Bob, Charlie,. . . ) can measure $M$ different observables with outcomes $\pm 1$: $\{A_{i_1}\}_{i_1=1}^M$ for Alice, $\{B_{i_2}\}_{i_2=1}^M$ for Bob and so on. By repeating the experiment several times, for each possible configuration of the observables (Alice measuring with the apparatus $A_{i_1}$, Bob with the apparatus $B_{i_2}$,. . .), they can obtain a good approximation of the expected value of the product of the outcomes of such configuration $\langle A_{i_1}B_{i_2}C_{i_3}\cdots \rangle$. If Nature is described by a LHV model, then

\[
\langle A_{i_1}B_{i_2}C_{i_3}\cdots \rangle = \langle A_{i_1}B_{i_2}C_{i_3}\cdots \rangle_p = \sum_s p(s)A_{i_1}(s)B_{i_2}(s)\cdots ,
\]

where $A_{i_1}(s) = \pm 1$ is the deterministic outcome obtained by Alice if she does the experiment $A_{i_1}$ and Nature is in state $s$ (notice that we are including also the locality condition when assuming that $A_{i_1}(s)$ is independent of $i_2,i_3,\ldots$).

For a quantum mechanical system in a state $\rho$ we have to set

\[
\langle A_{i_1}B_{i_2}C_{i_3}\cdots \rangle = \langle A_{i_1}B_{i_2}C_{i_3}\cdots \rangle_p = \text{tr}(\rho A_{i_1} \otimes B_{i_2} \otimes C_{i_3}\cdots )
\]

where $\rho$ is a density operator acting on a Hilbert space $C^{d_1} \otimes \cdots \otimes C^{d_N}$ and the observables satisfy $-\mathbb{1} \leq A_{i_1},B_{i_2},C_{i_3},\ldots \leq \mathbb{1}$, describing measurements within the framework of positive operator valued measures (POVMs). Note the parallelism with (1). In fact the quantum mechanical expression coincides with the classical one if the matrices $A_{i_1}$’s, $B_{i_2}$’s, . . . commute with each other (and therefore can be taken diagonal in some basis $|s\rangle$), and we take the state $\rho$ to be the separable state given by $\rho = \sum_s p(s)|s\rangle \otimes |s\rangle \otimes \cdots$.

How can one then know if Nature allows for a LHV description or follows Quantum Mechanics? That is, how to discriminate between (1) and (2)? The key idea of Bell [10] was to realize that this can be done by taking linear combinations of the expectation values $\langle A_{i_1}B_{i_2}C_{i_3}\cdots \rangle$. So, given real coefficients $T_{i_1 i_2 \cdots}$, if we maximize the expression

\[
\sum_{i_1,\ldots,i_N=0}^{M-1} T_{i_1\ldots i_N} \langle A_{i_1}B_{i_2}C_{i_3}\cdots \rangle
\]

assuming (1) we get [79]

\[
\|T\| := \sup_{a_{i_1},b_{i_2},c_{i_3},\ldots,=\pm 1} \left| \sum_{i\in\mathbb{Z}_{M}^N} a_{i_1}b_{i_2}c_{i_3}\cdots \right|.
\]
Therefore, if all correlations predicted by quantum mechanics could be explained in a classical and local world, one would have the following Bell inequality:

\[ \sum_{i,1,i_2,i_3,...} T_{1,i_2,i_3,...} \text{tr}(pA_{i_1} \otimes B_{i_2} \otimes C_{i_3} \cdot \cdot \cdot) \leq ||T||. \]  

(4)

However, Quantum Mechanics predicts examples for which we have a violation in (1). The largest possible violation of a given Bell inequality (specified by \( T \)) within quantum mechanics is the smallest constant \( K \) for which

\[ \sum_{i,1,i_2,i_3,...} T_{1,i_2,i_3,...} \text{tr}(pA_{i_1} \otimes B_{i_2} \otimes C_{i_3} \cdot \cdot \cdot) \leq K||T|| \]

(5)

holds independent of the state and the observables. For instance, for the CHSH inequality (\( M = 2, N = 2 \) and \( T \) the Hadamard matrix) we have \( K = \sqrt{2} \) irrespective of the Hilbert space dimension. More generally, if we also allow for arbitrary \( M \) and \( T \) and just fix \( N = 2 \), there is (see Section [II]) a universal constant (called Grothendieck’s constant) \( K_G \) that works in (5) for all Bell inequalities, states, and observables. This was firstly observed by Tsirelson [66] (see also [5]). As \( K_G \) is known to lie in between 1.676.. \( \leq K_G \leq 1.782.. \) the maximal Bell violation in Eq. (5) is bounded for bipartite quantum systems. This bound imposes some limitations to the use of Bell inequalities, where one usually desires as large violation as possible. Below, when talking about the implications of our main result, we will illustrate why having large violations can be useful in the contexts of communication complexity, quantum cryptography or noise robustness.

Therefore, it would be very useful to know whether in the tripartite case we still have a uniform bound for the violations. The first place in which we have found this question explicitely is in the review [66] of Tsirelson in 1993. Our main result will be to prove that this is not the case.

(We will in the following use \( \succeq, \simeq, \preceq \) to denote \( \geq, =, \leq \) up to some universal constant).

**Theorem 1** (Maximal violation for tripartite Bell inequalities).

1. For every dimension \( d \in \mathbb{N} \), there exist \( D \in \mathbb{N} \), a pure state \( |\psi\rangle \) on \( \mathbb{C}^d \otimes \mathbb{C}^D \otimes \mathbb{C}^D \) and a Bell inequality with traceless observables such that the violation by \( |\psi\rangle \) is \( \succeq \sqrt{d} \).

2. The (unnormalized) state can be taken \( |\psi\rangle = \sum_{1 \leq i \leq d, 1 \leq j, k \leq D} |j|U_i^\dagger |k\rangle \langle i|j\rangle \), where \( U_i \) are random unitaries.

3. The order \( \sqrt{d} \) is optimal in the sense that, conversely, for every state acting on \( \mathbb{C}^d \otimes \mathbb{C}^D \otimes \mathbb{C}^D \) and every Bell inequality with not necessarily traceless observables the violation is also \( \preceq \sqrt{d} \).

**FIG. 1:** Quantum circuit that provides highly non-local states. Apart from using a maximally entangled state as an input, it requires the implementation of a controlled unitary with random unitaries (that is, if the control qubit is in state \( |i\rangle \), the circuit applies the (random) unitary \( U_i \)).

This Theorem shows once more that random states exhibit unexpected extremal properties [1] [13] [34] [43]. Unfortunately, though we have a explicit form for these highly non-local states (see Figure 1), there are a couple of weaknesses in the above theorem, which mainly come from the techniques we use:

- We do not have any control on the growth of \( D \) with respect to \( d \).

- We do not have a explicit form for the family of inequalities for which we have unbounded violation. As it will be shown in the proof, for both the choice of the observables and the choice of the coefficients of the Bell inequality we will use a lifting argument, which in our case goes back to some application of Hahn-Banach’s theorem and the clever use of approximate unit in ideals of a \( C^\ast \)-algebra. This prevents us from having a constructive proof. It would be interesting to find these lifting in another way (even numerically or probabilistically).
It is important to note here (see Sec. IV) that in contrast to what is known for the $M = 2$ case [75], GHZ states do not belong to this set of highly non-local states—they always lead to a bounded violation. Let us now discuss some of the implications of Thm. 1.

**Communication complexity:** Using notions from [15] it was shown in [13] that for every quantum state that violates a Bell inequality there is a communication complexity problem for which a protocol assisted by that state is more efficient than any classical protocol. In fact, it turns out that there is a quantitative relation between the amount of violation and the superiority of the assisted protocol.

Adapted to our case, the communication complexity problem discussed in [13, 15, 50] is the following: Each of the three parties ($i = 1, 2, 3$) obtains initially a random bit string encoding $(x_i, y_i)$, where each $y_i = \pm 1$ is taken from a flat distribution and $x_i \in \{0, \ldots, M - 1\}$ is distributed according to $|T_x|/\sum_{x'} |T_{x'}|$ where $T_x = T_{x_1,x_2,x_3}$ are the coefficients appearing in the violated Bell inequality. The goal is now that every party first broadcasts a single bit and then attempts to compute the function

$$F(x, y) = \prod_i y_i T_x/|T_x|$$

upon the obtained information. The protocol was successful if all parties come to the right conclusion. If one compares the optimal classical protocol (assisted by shared randomness) with a protocol assisted by a quantum state violating the considered Bell inequality by a factor $K$, and denotes the respective probabilities of success by $P$ and $P_K$ then

$$P_K - \frac{1}{2} = \frac{1}{2} = K.$$  

Let us denote by $H(P)$ the binary entropy and quantify the information $I$ about the actual value of $F(x, y)$ gained by a protocol with success probability $P$ by $I(P) = 1 - H(P)$. Taking the states and inequalities appearing in Thm. 1 and thus setting $K \geq \sqrt{d}$ then leads to the ratio

$$\frac{I(P_K)}{I(P)} \geq d.$$  

**Measuring the size of the Hilbert space:** What do measured correlations tell us about a quantum system, if we do not have a priori knowledge about the observables or even the size of the underlying Hilbert space? This type of question becomes for instance relevant in the context of cryptography where one wants to avoid any kind of auxiliary assumption necessary for security [2, 8, 9, 46, 62]. In the context of detecting entanglement it is easy to see that the set of entanglement witnesses that remain meaningful when disregarding the Hilbert space dimension is exactly the set of Bell inequalities. In fact, if measured correlations do not violate any Bell inequality, then they can always be produced by a separable (i.e., unentangled) state in a sufficiently large Hilbert space [3]. Thm. 1 now shows that for multipartite systems the violation of a Bell inequality can in principle be used to estimate (lower bound) the Hilbert space dimension. It also answers a question posed by Masanes [43] in the negative: in contrast to the case $M = 2$ [44, 75] the extreme points of the set of quantum correlations observable with dichotomic measurements are in general not attained for multi-qubit systems.

**Robustness against noise and detector inefficiencies:** It is well known that for $M = 2$ the maximal quantum violation can increase exponentially in the number of sites $N$ [17, 75]. However, since the $N$ parties have to measure in coincidence, in practice with imperfect detectors, this increase comes with the handicap that also the coincidence rates then decrease exponentially. This becomes clearly different if one increases the violation without increasing $N$ as it is the case in Thm. 1. So, in spite of the opaqueness of our result concerning practical implementations it does not suffer from decreasing coincidence rates.

Similarly, Thm. 1 implies the existence of tripartite quantum states that can withstand an arbitrary amount of white noise before they admit a description within a local hidden variable model. To see this let $\rho$ belong to the family of states giving rise to a maximal violation $K \geq \sqrt{d}$ and set

$$\rho' = p\rho + (1 - p) \frac{1}{\text{tr}(\mathbb{1})}.$$  

As the violation $K$ is attainable for traceless observables, $\rho'$ yields $K' = pK$ which is still a violation whenever $p \geq 1/\sqrt{d}$ (see [5] for a similar reasoning in the bipartite case). In this context, it is a natural question to ask which is the amount of noise needed to disentangle a quantum state. It happens that this is considerably bigger. In particular, it is shown in [61] (in a constructive way) that:
Theorem 2 (Neighborhood of the maximally mixed state). Given $d$, there is an entangled state $\rho_d$ in $\mathbb{C}^d \otimes \mathbb{C}^d \otimes \mathbb{C}^d$ such that $\rho_d = pp_d + (1 - p) \frac{1}{d^3}$ is still entangled whenever $p \leq \frac{1}{2}$.

We will give an independent proof in the Appendix. Up to now the optimal value of $p$ is not known. The best bounds are given by $\frac{1}{3^3} \leq p \leq \frac{1}{3^3}$. It is also known that $\rho_d$ in Theorem 2 can be taken to be the generalized GHZ state $\left|23\right>$ in contrast to what we will see for the maximal violation of multipartite Bell inequalities.

III. MATHEMATICAL TOOLS

We will use tools from the theory of Operator Spaces and Tensor Norms. The use of one or the other will depend on the point of view of our problem. If we put the focus on the Bell inequalites and ask for the largest possible violation within Quantum Mechanics, then we will work with Operator Spaces and the meta-theorem we have is the following (for a precise formulation see below):

A Bell inequality for $N$ observers and $M$ dichotomic observables per site is given by a $N$-linear form $T : \ell^M_\infty \times \cdots \times \ell^M_\infty \rightarrow \mathbb{C}$ with $\|T\| = 1$. The largest possible violation within Quantum Mechanics is given by the completely bounded norm of $T$, $\|T\|_{cb}$.

If, however, we put the focus on the quantum states and ask, given a $N$-partite quantum state, which is the largest possible violation that this state gives to a Bell inequality, then we will work with the theory of Tensor Norms, and the meta-theorem now reads:

The largest possible violation that a $N$-partite $D \times \cdots \times D$ state $\rho$ gives to a Bell inequality (with an arbitrarily number of dichotomic observables) is given by the extendible tensor norm

$$\|\rho\|_{\otimes_{i=1}^{N} \mathbb{C}^{D_i}} S^P.$$  

Operator spaces

The theory of operator spaces started with the work of Effros and Ruan in the 80’s (see e.g. [26, 59]) where they characterized, in an abstract sense, the structure of a subspace of a $C^*$-algebra. Since then, this theory has found some interesting applications in mathematical analysis. An operator space is a complex vector space $E$ and a sequence of norms $\|\cdot\|_n$ in the space of $E$-valued matrices $M_n(E) = M_n \otimes E$, which verify the properties

1. For all $n$, $x \in M_n(E)$ and $a, b \in M_n$ we have that $\|axb\|_n \leq \|a\|_{M_n} \|x\|_n \|b\|_{M_n}$.
2. For all $n, m$, $x \in M_n(E)$, $y \in M_m(E)$, we have that

$$\left\|\begin{pmatrix} x & 0 \\ 0 & y \end{pmatrix}\right\|_{n+m} = \max\{\|x\|_n, \|y\|_m\}$$

Any $C^*$-algebra has a natural operator space structure that is the resulting of embedding it inside the space $B(H)$ of bounded linear operators in a Hilbert space [26, 59], where $M_n(B(H)) = B(\ell^2_n \otimes H)$. In particular, $\ell^k_\infty (= C^k$ with the sup-norm), being a commutative $C^*$-algebra, has a natural operator space structure. To compute it we embed $\ell^k_\infty$ in the diagonal of $M_k$ (with the operator norm) and then, given $x = \sum_i A_i \otimes |i\rangle \langle i|$ $\in M_n(\ell^k_\infty) = M_n \otimes \ell^k_\infty$, we have

$$\|x\|_n = \max_i \|A_i\|_{M_n}.$$  

The morphisms in the category of operator spaces (that is, the operations that preserve the structure) are called completely bounded maps. They are linear maps $u : E \rightarrow F$ between operator spaces such that all the amplifications $u_n = u \otimes i : M_n(E) \rightarrow M_n(F)$ are bounded. The cb-norm of $u$ is then defined as $\|u\|_{cb} = \sup_n \|u_n\|$. We will call $CB(E,F)$ the resulting normed space, that is, in fact, an operator space by $M_n(CB(E,F)) = CB(E_n,F)$. Analogously one can define the cb-norm of a multilinear map $T : E_1 \times \cdots \times E_N \rightarrow F$ as $\|T\|_{cb} = \sup \|T_{n_1,\ldots,n_N}\|$, where now $T_{n_1,\ldots,n_N} = T \otimes 1_{n_1} \otimes \cdots \otimes 1_{n_N} : M_{n_1}(E_1) \times \cdots \times M_{n_N}(E_N) \rightarrow M_{n_1,\ldots,n_N}(F)$. A multilinear map is called
completely bounded if $\|T\|_{cb} \leq \infty$. We will denote by $CB^N(E_1, \ldots, E_N; F)$ the resulting normed space, that is also an operator space by $M_n(CB^N(E_1, \ldots, E_N; F)) = CB^N(E_1, \ldots, E_N; M_n(F))$.

With these definitions, if we have a $N$-linear form $T: \ell^M_\infty \times \cdots \times \ell^M_\infty \rightarrow \mathbb{C}$ given by $T(|i_1\rangle, |i_2\rangle, \ldots) = T_{i_1i_2...}$ and we compute the usual norm and the $cb$-norm we obtain:

$$\|T\| = \sup \left\{ \sum_{i_1, \ldots, i_N=0}^{M-1} T_{i_1i_2\ldots} e_1^1 e_2^2 \cdots : |e_i^j| \leq 1 \right\},$$

$$\|T\|_{cb} = \sup \left\{ \sum_{i_1, \ldots, i_N=0}^{M-1} T_{i_1i_2\ldots} \text{tr}(\rho A_{i_1} \otimes B_{i_2} \cdots) : A_{i_1}, B_{i_2}, \ldots \in M_D \text{ with operator norm } \leq 1 \right\}.$$

These expressions coincide respectively with the maximal value that one can achieve in the expression (3).

In [32], Grothendieck proved what he called the fundamental theorem of the metric theory of tensor products. This result, known as Grothendieck’s Theorem or Grothendieck’s Inequality reads as follows:

There exists a universal constant $K_G$ such that no matter how we choose real coefficients $T_{ij}$ and elements $x_i, y_j$ in the unit ball of a real Hilbert space $H$ with inner product $(\cdot, \cdot)$, we have that

$$\left| \sum_{ij} T_{ij} \langle x_i, y_j \rangle \right| \leq K_G \sup_{\epsilon_i, \nu_j = \pm 1} \left| \sum_{ij} T_{ij} \epsilon_i \nu_j \right|.$$

In particular,

$$\left| \sum_{ij} T_{ij} \text{tr}(\rho A_i \otimes B_j) \right| \leq K_G \sup_i \|A_i\| \sup_j \|B_j\| \sup_{\epsilon_i, \nu_j = \pm 1} \left| \sum_{ij} T_{ij} \epsilon_i \nu_j \right|. \quad (11)$$

The second part tells us that Grothendieck’s Theorem provides a uniform bound $K_G$ for the violation of any bipartite Bell inequality with dichotomic observables. This was essentially Tsirelson’s observation [63].

But the above comments show how Grothendieck’s Theorem also implies that any bounded bilinear form from a commutative $C^*$-algebra has to be also completely bounded, which was firstly noticed in [33].

Since Grothendieck stated his Theorem, a lot of effort has been devoted to find suitable multilinear generalizations (see for instance [11] [12] [17] [51] [54] [65]). However, up to know, the validity of a trilinear Grothendieck’s Theorem in the context of operator spaces (and hence in the context of Bell inequalities) has been open. Although it is conceivable that trilinear versions of Grothendieck’s inequality hold for operator spaces, our main theorem (Theorem 1) will show that the trilinear version of (11) fails. We will rewrite this now in the language of operator spaces which is instrumental in the proof. Then we will show how this Theorem implies Theorem 1 and we will give the proof in Section 5.

**Theorem 3.** For every $n$, there exist $N$, a state $|\psi_N\rangle$, a trilinear form $T: \ell^N_\infty \times \ell^N_\infty \times \ell^N_\infty \rightarrow \mathbb{C}$ and elements $b \in M_n(\ell^N_\infty)$, $\hat{b} \in M_n(\ell^N_\infty)$, with $|||\psi_N|||, ||T||, ||b||, ||\hat{b}|| \leq 1$ and

$$\langle \psi_N | T_{n, n, n} (b, \hat{b}, \hat{b}) | \psi_N \rangle \geq \sqrt{n}.$$

Moreover
1. The order $\sqrt{n}$ is optimal.

2. $|\psi_N\rangle$ can be taken $\frac{1}{\sqrt{n}} \sum_{1 \leq i \leq n \leq j \leq N} \langle j | U_{N,i}^\dagger | k \rangle |ijk\rangle$ where $U_{N,i}$ are random unitaries.

Again we use $\geq$ (resp. $\simeq$) to denote $\geq$ (resp. $=$) up to some universal constant. In particular, we obtain that

**Corollary 4** (Bounded but not completely bounded trilinear forms). Given $n$, there exists $N$ and a trilinear map $T : \ell^\infty_\mathbb{C} \times \ell^\infty_\mathbb{C} \times \ell^\infty_\mathbb{C} \rightarrow \mathbb{C}$ such that $\|T\|_b \geq \|T_{n,N,N}\| \geq \sqrt{n}|T|$. Moreover, the order $\sqrt{n}$ is optimal.

We will finish this section by showing how Theorem 3 implies Theorem 1. As we said before, it is simply a matter of splitting into real and imaginary parts.

Theorem 3 tells us that there exist a complex matrix $\{T_{ijk}\}_{i,j,k=1}^N$, $n \times n$ matrices $b_i$ and $N \times N$ matrices $\hat{b}_j$ (all of them with norm $\leq 1$) such that

$$\left| \langle \psi_N | \sum_{i,j,k} T_{ijk} b_i \otimes \hat{b}_j \otimes \hat{b}_k | \psi_N \rangle \right| \geq \sqrt{n}.$$  \hspace{1cm} (12)

By splitting into real and imaginary parts it is not difficult to see that one can take in (12) $T$ real and $b_i, \hat{b}_j$ hermitian. Moreover, writing $\alpha_i = \frac{\text{tr}(b_i)}{n}$ (so that $|\alpha_i| \leq 1$), $b_i^1 = \alpha_i \mathbb{1}_n$, $b_i^0 = b_i - b_i^1$ and applying the bipartite case to show that $(\rho = |\psi_N\rangle \langle \psi_N|)$

$$\left| \sum_{i,j,k} \text{tr}(\rho T_{ijk} b_i^1 \otimes \hat{b}_j \otimes \hat{b}_k) \right| = \left| \sum_{i,j,k} T_{ijk} \alpha_i \text{tr}(\rho_{2,3} \hat{b}_j \otimes \hat{b}_k) \right| \leq K_G,$$

one can take the observables in (12) to be traceless.

**Tensor norms**

The theory of tensor norms can be traced back to the work of Murray and von Neumann in the late 30’s, but it was definitely set by Grothendieck in his seminal paper [32]. Since then, several and important contributions have been made (see [22] for a modern reference).

If $X_1, \ldots, X_N$ are normed spaces, by $\bigotimes_{j=1}^N X_j$ we denote the algebraic tensor product $\bigotimes_{j=1}^N X_j$ endowed with the projective norm

$$\pi(u) := \inf \left\{ \sum_{i=1}^m \|u_i^1\| \cdots \|u^N_i\| : u = \sum_{i=1}^m u^1_i \otimes \cdots \otimes u^N_i \right\}.$$  

This tensor norm is both commutative and associative, in the sense that $\bigotimes_{j=1}^N X_j = \bigotimes_{j=1}^N X_{\sigma(j)}$ for any permutation of the indices $\sigma$ and that $\bigotimes_{j=1}^N \left( \bigotimes_{j=1}^N X_{i_j} \right) = \bigotimes_{j=1}^N X_j$. The projective norm $\pi$ is in duality with the injective norm $\epsilon$, defined on $\bigotimes_{j=1}^N X_j$ as

$$\epsilon(u) := \sup \left\{ \left| \sum_{i=1}^m \phi^1(u_i^1) \cdots \phi^N(u_i^N) \right| : \phi^j \in X_j^*, \|\phi^j\| \leq 1 \right\},$$

where $X_j^*$ denotes the topological dual of $X_j$ and $u = \sum_{i=1}^m u_i^1 \otimes \cdots \otimes u_i^N$. That is, if $E_j$ is a finite dimensional normed space for every $j = 1, \ldots, N$, we have $\left( \bigotimes_{j=1}^N E_j \right)^* = \bigotimes_{j=1}^N E_j^*$ and $\bigotimes_{j=2}^N E_j^*$. Moreover, the dual of the $\pi$ tensor product can also be isometrically identified with the space of $N$-linear forms (with its usual operator norm). In fact, we have the natural isometric identification,

$$\mathcal{L}^N(E_1, \ldots, E_N; \mathbb{C}) = \left( \bigotimes_{j=1}^N E_j \right)^* = \mathcal{L}(E_{1,2}, \ldots, E_{N,1}^*).$$ \hspace{1cm} (13)
Following \cite{22} (or \cite{30} for the multilinear version) we define a tensor norm $\beta$ of order $N$ as a way of assigning to every $N$-tuple of normed spaces $(X_1, \ldots, X_N)$ a norm on $\bigotimes_{j=1}^{N} X_j$ (we call $\bigotimes_{j=1, \beta} X_j$ to the resulting normed space) such that

- $\epsilon \leq \beta \leq \pi$
- $\left\| \bigotimes_{j=1}^{N} u_j : \bigotimes_{j=1, \beta} X_j \longrightarrow \bigotimes_{j=1, \beta} Y_j \right\| \leq \prod_{j=1}^{N} \| u_j \|$, for every choice of linear bounded operators $u_j : X_j \longrightarrow Y_j$. This is called the metric mapping property.

Sometimes we will use the notation $\bigotimes_{\beta}(X_1, \cdots, X_N)$ instead of $\bigotimes_{j=1, \beta} X_j$ to distinguish some space.

We will say that $\beta$ is finitely generated if, for every $X_j$, $j = 1, \cdots, N$, and $z \in \bigotimes_{j=1}^{N} X_j$ we have

$$\beta(z; X_1, \cdots, X_N) = \inf \{ \beta(z; E_1, \cdots, E_N) : E_j \in FIN(X_j), z \in \bigotimes_{j=1}^{N} E_j \};$$

where we denote $FIN(X) = \{ E \subset X | \dim E < \infty \}$ (and $COFIN(X) = \{ E \subset X | E$ is closed and $\dim(X/E) < \infty \}$).

As one can find in \cite{22} Sec. 17 and \cite{30} Sec. 4 tensor norms are in one-to-one duality with ideals of multilinear operators. We explain this in which follows:

A normed (Banach) ideal of $N$-linear continuous operators between Banach spaces is a pair $(\mathcal{A}, \| \cdot \|_{\mathcal{A}})$ such that

- $\mathcal{A}(X_1, \cdots, X_N; Y) = \mathcal{A} \cap \mathcal{L}^N(X_1, \cdots, X_N; Y)$ is a linear subspace of $\mathcal{L}^N(X_1, \cdots, X_N; Y)$ and the restriction $\| \cdot \|_{\mathcal{A}}|_{\mathcal{A}(X_1, \cdots, X_N; Y)}$ is a (complete) norm.
- If $u_j \in \mathcal{L}(Z_j, X_j)$, $T \in \mathcal{A}(X_1, \cdots, X_N; Y)$ and $v \in \mathcal{L}(Y, Z)$, then the composition $v \circ T \circ (u_1, \cdots, u_N)$ is in $\mathcal{A}$, and

$$\| v \circ T \circ (u_1, \cdots, u_N) \|_{\mathcal{A}} \leq \| v \|_{\mathcal{A}} \| T \|_{\mathcal{A}} \| u_1 \| \cdots \| u_N \|.$$

- The operator $K^N \ni (x_1, \cdots, x_N) \mapsto x_1 \cdots x_N \in K$ is in $\mathcal{A}$ and it has $\| \cdot \|_{\mathcal{A}}$-norm equal to one.

An ideal $(\mathcal{A}, \| \cdot \|_{\mathcal{A}})$ is called maximal if $\| T \|_{\mathcal{A}} = \sup \{ \| T \|_{\mathcal{A}} : T \in FIN(X_j), L \in COFIN(Y) \} < \infty$ implies $T \in \mathcal{A}$ and $\| T \|_{\mathcal{A}} = \| T \|_{\mathcal{A}}$.

The following theorem shows the duality mentioned above

**Theorem 5.** Let $(\mathcal{A}, \| \cdot \|_{\mathcal{A}})$ be a normed ideal of $N$-linear continuous mappings between Banach spaces. Then $(\mathcal{A}, \| \cdot \|_{\mathcal{A}})$ is maximal if and only if there exists a finitely generated tensor norm $\beta$ of order $N+1$ such that

$$\mathcal{A}(X_1, \cdots, X_N; Y^*) = (\bigotimes_{\beta}(X_1, \cdots, X_N, Y))^*,$$

$$\mathcal{A}(X_1, \cdots, X_N; Y) = (\bigotimes_{\beta}(X_1, \cdots, X_N, Y^*))^* \cap \mathcal{L}^N(X_1, \cdots, X_N; Y).$$

Here both identifications are isometric.

For the purposes of this paper we will only need two of these ideals: the extendible and the $(1; 2)$-summing multilinear operators.

**Extendible multilinear operators**

The lack of a multilinear Hahn-Banach extension theorem has motivated a considerable effort in the search of partial positive results (see \cite{10} \cite{15} \cite{33} \cite{53} and the references therein). In this context, the natural space to work with is the space of extendible multilinear forms. That is, those continuous multilinear forms $T : X_1 \times \cdots \times X_n \longrightarrow \mathbb{C}$ (here $X_j$ are Banach spaces) such that for every choice of superspaces $Y_j' \supset X_j$, there is a continuous and multilinear extension $\tilde{T} : Y_1 \times \cdots \times Y_n \longrightarrow \mathbb{C}$. We define the extendible norm of $T$ as

$$\| T \|_{\text{ext}} = \sup_{Y_j'} \| \tilde{T} \|,$$
where the sup runs among all possible superspaces $Y_j$ and the inf among all possible extensions $\hat{T}$. As it can be found in [15], for infinite dimensional spaces $X_j$, $\|T\|_{\text{ext}}$ can be in general $\infty$. We say then that $T$ is extendible if $\|T\|_{\text{ext}} < \infty$.

It can be easily seen that the extendible n-linear forms constitute a Banach ideal, which we denote by $\mathcal{L}_{\text{ext}}^n$. Actually, it is trivial to check that $(\bigotimes_{j=1}^n \alpha_{\text{ext}} X_j)^* = \mathcal{L}_{\text{ext}}(X_1, \cdots, X_n)$ isometrically, if we define the well known ([37], Sec. 3) finitely generated tensor norm

$$
\alpha_{\text{ext}}(u; X_1, \cdots, X_n) = \inf \{ \pi(u; Y_1, \cdots, Y_n) : X_j \subset Y_j \},
$$

where the inf is taken among all superspaces $Y_j$ of $X_j$.

$\alpha_{\text{ext}}$ is called the extendible tensor norm (and it is, of course, the tensor norm associated to the ideal of extendible multilinear forms in the sense of Theorem [5]).

The next lemma will be a central result to connect this mathematical theory with the context of Bell inequalities:

**Lemma 6.** Let $X_1, \cdots, X_n$ be n Banach spaces and $u \in \bigotimes_{j=1}^n X_j$. We have

$$
\alpha_{\text{ext}}(u) = \sup_{M_i, A_{i1}^n} \left| \sum_{i_1, \cdots, i_n} A_{i1}^n \langle A_{i1}^n \otimes \cdots \otimes A_{in}^n, u \rangle \right|,
$$

where the sup is taken among $(A_{i1}^n)^k_{i_1=1} \subset B_{X_1^n}, \cdots, (A_{in}^n)^k_{i_1=1} \subset B_{X_n^n}$, $\|\langle M_i, A_{i1}^n \rangle \|_{\bigotimes_{j=1}^n \ell^\infty} \leq 1$, $k \in \mathbb{N}$, and the brackets denote as usual the action by duality.

**Proof.** By the injectivity of $\ell^\infty$ (see for instance [22, Chap I.1]), it follows that

$$
\alpha_{\text{ext}}(u) = \sup \left\{ \|a_1 \otimes \cdots \otimes a_n(u)\|_{\bigotimes_{j=1}^n \ell^\infty} : a_j : X_j \to \ell^\infty, \|a_j\| \leq 1, j = 1, \cdots, n; k \in \mathbb{N} \right\}.
$$

Now, we know that $\mathcal{L}(X_j, \ell^k)$ is isometrically isomorphic to $\ell^k(X_j^*)$ (see for instance [22, Chap I.3]). Thus, given $a_j \in \mathcal{L}(X_j, \ell^k) = \ell^k(X_j^*)$ by $a_j = \sum_{i=1}^k |i_j\rangle \otimes A_{i}$, we have

$$
\|a_1 \otimes \cdots \otimes a_n(u)\|_{\bigotimes_{j=1}^n \ell^\infty} = \| \sum_{i_1, \cdots, i_n} \langle A_{i1}^n \otimes \cdots \otimes A_{in}^n, u \rangle |i_1\rangle \otimes \cdots \otimes |i_n\rangle \|_{\bigotimes_{j=1}^n \ell^\infty} = \sup \left\{ \sum_{i_1, \cdots, i_n} \langle A_{i1}^n \otimes \cdots \otimes A_{in}^n, u \rangle T(|i_1\rangle, \cdots, |i_n\rangle) : T \in B(\bigotimes_{j=1}^n \ell^\infty)^* \right\}.
$$

The statement follows now easily.

**Theorem 7.** Given a $N$-partite $D_1 \times \cdots \times D_N$ quantum state $\rho$, the largest possible violation that this state gives to a Bell inequality of an arbitrarily number of dichotomic observables is upper bounded by

$$
2^{N-1}\|\rho\|_{\bigotimes_{j=1}^n \alpha_{\text{ext}} S_{D_j}^1}.
$$

**Proof.** Given a Bell inequality with (real) coefficients $T_{i_1, i_2, \cdots}$ and observables $-\mathbb{I} \leq A_{i_1}, B_{i_2}, \cdots \leq \mathbb{I}$, it is clear by the definition of $\alpha_{\text{ext}}$ that

$$
\sum_{i_1, i_2, \cdots} T_{i_1, i_2, \cdots} \text{tr}(\rho A_{i_1} \otimes B_{i_2} \otimes \cdots) \leq \|\rho\|_{\bigotimes_{j=1}^n \alpha_{\text{ext}} S_{D_j}^1} \sup_{\epsilon_{i_j} = \pm 1} \sum_{i_1, i_2, \cdots} T_{i_1, i_2, \cdots} \epsilon_{i_1} \epsilon_{i_2} \cdots.
$$

To finish the proof of the Theorem it is enough to notice that (see [49, Proposition 19])

$$
\sup_{\epsilon_{i_j} = \pm 1} \left| \sum_{i_1, i_2, \cdots} T_{i_1, i_2, \cdots} \epsilon_{i_1} \epsilon_{i_2} \cdots \right| \leq 2^{N-1} \sup_{\epsilon_{i_j} = \pm 1} \left| \sum_{i_1, i_2, \cdots} T_{i_1, i_2, \cdots} \epsilon_{i_1} \epsilon_{i_2} \cdots \right|.
$$

\[\square\]
Summing operators

Since the work of Grothendieck [32], the class of absolutely summing linear operators plays a crucial role in the theory of tensor norms (see [25] for a reference). Motivated by that, A. Pietsch defined in [55] the following class of multilinear operators:

A multilinear form $T : X_1 \times \cdots \times X_N \rightarrow \mathbb{C}$ is called $(s; r)$-summing (1 ≤ s, r < ∞) if there exists a constant $K$ such that for any choice of finite sequences $(x_i^j)_i \subset X_j$, we have that

$$\left( \sum_i |T(x_1^1, \ldots, x_N^N)|^r \right)^{\frac{1}{r}} \leq K \prod_j \|x_i^j\|_r^s,$$

where $\|x_i^j\|_r$ denotes the supremum, among all elements $x_i^j$ in the unit ball of the dual space $X_j^*$, of

$$\left( \sum_i |x_i^j(x_i^j)|^r \right)^{\frac{1}{r}}.$$

The smallest $K$ valid in equation (14) is called the $(s; r)$ norm of $T$, and we write $\|T\|_{(s; r)}$. The key result is the following generalization of Grothendieck’s inequality, which appears explicitly in [51, Corollary 2.5] (see also [11, 17, 35, 65]).

**Theorem 8.** Every extendible $N$-linear form $T$ is $(1; 2)$-summing and $\|T\|_{(1; 2)} \leq K_G 2^{\frac{N}{2}} k_{ext}$, where $K_G$ is Grothendieck’s constant.

IV. BOUNDED VIOLATIONS FOR GHZ STATES

The maximal violation of multipartite Bell inequalities with two dichotomic observables per site [47, 75, 78] is known to be attained for GHZ states $|\psi\rangle = \frac{1}{\sqrt{N}} \sum_{i=0}^{N-1} |iii\rangle$ (where $n = 2$ is sufficient in this case). In contrast to that, we will show here that GHZ states do not give rise to the maximal violation in Thm.1 but rather lead to a bounded violation. In other words, there is a fixed amount of noise (independent of the dimension) which makes the considered correlations of the GHZ state admit a description within a local hidden variable model.

Before proving that we need a bit of work. We call $\rho$ the unnormalized GHZ state $\sum_{i=1}^{\infty} |i\rangle \otimes |i\rangle \otimes |i\rangle \langle i|$ as a member of $\bigotimes_{j=1}^{3} S_1^{n_1}$ (the Banach space of trace class operators on a $n$-dimensional Hilbert space $\ell_2^n$). When we consider a tensor norm $\alpha$ on $\bigotimes_{j=1}^{3} S_1^{n_1}$, $\alpha^*$ will be the same element as $\rho$, but considered in the dual $(\bigotimes_{j=1}^{3} S_1^{n_1})^*$. The key point is the following result,

**Proposition 9.** For every tensor norm $\alpha$,

$$\|\rho\|_{\bigotimes_{j=1}^{3} S_1^{n_1}} \cdot \|\alpha^*\|_{\bigotimes_{j=1}^{3} S_1^{n_1}} = n^2.$$

We will follow [31, Theorem 2.5]. First we will need the next

**Lemma 10.** Let $\alpha$ be any tensor norm and $A = \bigotimes_{j=1}^{3} S_1^{n_1}$. Let $G$ be a topological compact group such that $G \subset \text{isom}(A, A)$, the group of isometries of $A$. We suppose:

(i) $\alpha^* \rho$ for every $g \in G$.

(ii) Given $L \in A^*$, if $L \circ g = L$ for every $g \in G$, then $L = \alpha \rho$ for some constant $\lambda$.

Then we have that $\|\rho\|_{A^*} \cdot \|\alpha^*\|_{A^*} = n^2$.

**Proof.** Let us take $L \in A^*$ such that $\|L\|_{A^*} = 1$ and $L(\rho) = \|\rho\|_{A^*}$. Let $dg$ be the Haar measure on $G$. We define $L_0 = \int_G L \circ g dg$. It is easy to see that $L_0$ is well defined and belongs to $A^*$ with $\|L_0\|_{A^*} \leq \|L\|_{A^*}$. Now, by (i),

$$L_0(\rho) = \int_G L \circ g \rho dg = L(\rho).$$

On the other hand, for every $g' \in G$ we have $L_0 \circ g' = \int_G L \circ g \circ g' dg = \int_G L \circ g dg = L_0$, where we have used the translational invariance of the Haar measure. Using (ii) we conclude that $L_0 = \lambda \rho^\ast$. We have

$$\|\rho\|_A = L(\rho) = L_0(\rho) = \lambda \rho^\ast (\rho) = \lambda n^2.$$
And also
\[ \lambda \|\rho^*\|_{A^*} = \|\lambda \rho^*\|_{A^*} = \|L_0\|_{A^*} \leq \|L\|_{A^*} = 1. \]

Then \( \|\rho^*\|_{A^*} \leq \frac{1}{\lambda} \), and thus \( \|\rho\|_{A^*} \cdot \|\rho^*\|_{A^*} \geq n^2 \). The other inequality is trivial.

Using the previous lemma we can easily prove Proposition 9.

**Proof.** We only need to show that there exists a topological compact subgroup of \( \text{isom}(A, A) \) which verifies the hypothesis of Lemma 11.

For every \( \varepsilon = (\varepsilon_1, \varepsilon_2, \ldots, \varepsilon_n) \), where \( \varepsilon_i = \pm 1 \), we consider \( g_\varepsilon : C^n \rightarrow C^n \) such that \( g_\varepsilon(|i\rangle) = \varepsilon_i|i\rangle \). For every \( \sigma \) permutation of \( \{1, \ldots, n\} \) we consider \( h_\sigma : C^n \rightarrow C^n \) such that \( h_\sigma(|i\rangle) = |\sigma(i)\rangle \). Now we take the group \( G \) generated by the elements of the form

\[ (g_\varepsilon^* \otimes g_\delta^* \otimes g_\eta^* \otimes \text{id}) \otimes (g_\varepsilon^* \otimes g_\delta^* \otimes g_\eta^*) \text{ and } (h_\sigma^* \otimes h_\tau^*) \otimes (h_\sigma^* \otimes h_\tau^*) \text{ and } (g_\varepsilon^* \otimes g_\delta^* \otimes g_\eta^*) \text{ and } (g_\varepsilon^* \otimes g_\delta^* \otimes g_\eta^* \otimes \text{id}). \]

It is clear that \( G \) is a compact subgroup of \( \text{isom}(A, A) \) and that \( G \) verifies (i). Let us check (ii). Let

\[ L = \sum_{i,j,k,l,m,n} \lambda_{i,j,k,l,m,n} |i\rangle \langle j| \otimes |k\rangle \langle l| \otimes |m\rangle \langle n| \]

be an arbitrary element of \( A^* \). We take \( g = (g_\varepsilon^* \otimes g_\delta^* \otimes \text{id}) \otimes (g_\varepsilon^* \otimes g_\delta^*) \) in \( G \). If we have \( L = L \circ g \), we get, for every \( i, j, k, l, m, n \),

\[ \lambda_{i,j,k,l,m,n} = \lambda_{i,j,k,l,m,n} \varepsilon_i \varepsilon_j \varepsilon_m \theta_n, \]

for every choice of signs \( \varepsilon_i, \theta_j \). Therefore, \( \lambda_{i,j,k,l,m,n} = \lambda_{i,j,k,l,m,n} \delta_i \delta_j \delta_m \delta_n \). Then

\[ L = \sum_{i,j,k,l} \lambda_{i,j,k,l} |i\rangle \langle j| \otimes |k\rangle \langle l| \otimes |i\rangle \langle j|. \]

We can repeat the step before (taking now \( g = (g_\varepsilon^* \otimes g_\delta^* \otimes g_\eta^*) \otimes \text{id} \) to see that, in fact,

\[ L = \sum_{i,j} \lambda_{i,j} |i\rangle \langle i| \otimes |i\rangle \langle i|. \]

Finally, taking \( g = (h_\sigma^* \otimes h_\delta^* \otimes h_\tau^*) \otimes (h_\sigma^* \otimes h_\tau^*) \in G \), we see that \( \lambda_{i,j} = \lambda_{\sigma(i), \tau(j)} \) for every permutations \( \tau, \sigma \) and every \( i, j \). Then, we get that \( \lambda_{i,j} = \lambda \), which finishes the proof.

And finally we can get the desired bound for the GHZ violation:

**Theorem 11 (GHZ bound).** Given the tripartite GHZ state \( |\psi\rangle = \frac{1}{\sqrt{2}} \sum_{i=0}^{n-1} |iii\rangle \), the largest possible quantum violation for a Bell inequality with dichotomic observables is upper bounded by \( 4\sqrt{2} K_G \).

**Proof.** By Theorem 7 it is enough to show that for the unnormalized GHZ state \( \rho = \sum_{i,j=0}^{n-1} |i\rangle \langle j| \otimes |i\rangle \langle j| \otimes |i\rangle \langle j| \) we have \( \|\rho\|_{S_{1,2};(S^n)} \leq K \cdot n \). Due to Proposition 9 we only have to prove that \( \|\rho^*\|_{S_{1,2};(S^n)} \geq n \). To see this, we use that by Theorem 8 \( \|\tau\|_{S_{1,2};(S^n)} \leq K \|\tau\|_{S_{1,2};(S^n)} \), and then it remains to be proven that \( \|\rho^*\|_{S_{1,2};(S^n)} \geq n \). For that we consider the sequence \( \{|r\rangle(0)\}_{r=1}^{\sqrt{2} K_G} \subset S^n \), which verifies \( \|\{r\rangle(0)\} \|_{S^n} \leq 1 \), and \( \sum_{r} \rho^* \langle r| \langle r| \rangle \langle r| \langle r\rangle = n \).

**Remark 12.** Note that Theorem 11 holds also for \( N \) parties, where now the constant can be taken \( K_G(2\sqrt{2})^{N-1} \). In [76] an explicit set of inequalities was derived for which GHZ states achieve a violation of the order \( (\pi/2)^N \).
V. PROOF OF THE MAIN THEOREM

More on operator spaces

Ruan’s Theorem [26, 56, 59] assures that any operator space can be considered as a closed subspace of $\mathcal{B}(H)$ with the inherited sequence of matrix norms. Then we can define the minimal tensor product of two operator spaces $E \subset \mathcal{B}(H)$ and $F \subset \mathcal{B}(K)$ as the operator space given by

$$E \otimes_{\text{min}} F \subset \mathcal{B}(H \otimes K).$$

In particular, $M_n(E) = M_n \otimes_{\text{min}} E$ for every operator space $E$. The tensor norm $\min$ in the category of operator spaces will play the role of $\epsilon$ in the classical theory of tensor norms. In particular it is injective, in the sense that if $E \subseteq X$ and $F \subseteq Y$, then $E \otimes_{\text{min}} F \subseteq X \otimes_{\text{min}} Y$ as operator spaces. The analogue of the $\pi$ tensor norm is the projective tensor norm, defined as

$$\|u\|_{M_n(E \otimes^p F)} = \inf \{ \|\alpha\|_{M_n,E} \|x\|_{M_n(E)} \|y\|_{M_n(F)} : u = \alpha(x \otimes y)\beta\},$$

where $u = \alpha(x \otimes y)\beta$ means the matrix product

$$u = \sum_{r,s,ijpq} \alpha_{r,ip} \beta_{jq,s} |r\rangle \langle s| \otimes x_{ij} \otimes y_{pq} \in M_n \otimes E \otimes F.$$

Both tensor norms $\wedge$ and $\min$ are associative and commutative and they share the duality relations of their classical counterparts $\pi$ and $\epsilon$. In fact, for finite dimensional operator spaces we have the natural completely isometric identifications

$$(E \otimes^p F)^* = CB^2(E, F; \mathbb{C}) = CB(E, F^*) = E^* \otimes_{\text{min}} F^*,$$ (15)

where, given an operator space $E$, we define its dual operator space $E^*$ via the identification $M_n(E^*) = CB(E, M_n)$.

Depending on the way one embeds a Banach space inside $\mathcal{B}(H)$, the same Banach space can have a completely different operator space structure. This happens even in the simplest example: the case of a Hilbert space. A trivial way of embedding a finite dimensional Hilbert space $\ell^2_n$ inside some $\mathcal{B}(H)$ is to put it into the first column (resp. row) of $M_n$, that is, $|i\rangle \mapsto |i\rangle \langle 0|$ (resp. $|i\rangle \mapsto |0\rangle \langle i|$). This gives us the column operator space $C_n$ (resp. the row operator space $R_n$). It is trivial to verify

$$\left\| \sum_i A_i \otimes |i\rangle \right\|_{M_n \otimes_{\text{min}} R_n^*} = \left\| \sum_i A_i A_i^\dagger \right\|^{1/2}_{M_n \otimes_{\text{min}} C_n}, \quad \left\| \sum_i A_i \otimes |i\rangle \right\|_{M_n \otimes_{\text{min}} C_n} = \left\| \sum_i A_i^\dagger A_i \right\|^{1/2}_{M_n \otimes_{\text{min}} C_n}.$$

We can also define the intersection of these two operator spaces $RC_n = R_n \cap C_n$, where given two operator spaces $E, F$ [56, page 55]

$$\| \cdot \|_{M_n \otimes_{\text{min}} E \cap F} = \max \{ \| \cdot \|_{M_n \otimes_{\text{min}} E}, \| \cdot \|_{M_n \otimes_{\text{min}} F} \}.$$

We will denote by $RC_n^2$ to $RC_n \otimes_{\text{min}} RC_n$. We have the following concrete expressions

$$\left\| \sum_i A_i \otimes |i\rangle \right\|_{M_n \otimes_{\text{min}} RC_n^2} = \max \left\{ \left\| \sum_i A_i A_i^\dagger \right\|^{1/2}_{M_n \otimes_{\text{min}} RC_n^2}, \left\| \sum_i A_i^\dagger A_i \right\|^{1/2}_{M_n \otimes_{\text{min}} RC_n^2} \right\}, \quad \left\| \sum_{ij} A_{ij} \otimes |ij\rangle \right\|_{M_n \otimes_{\text{min}} RC_n^2} = \max \left\{ \left\| \sum_i A_i A_i^\dagger \right\|^{1/2}_{M_n \otimes_{\text{min}} RC_n^2}, \left\| \sum_i A_i\right\| A_i^\dagger \right\|^{1/2}_{M_n \otimes_{\text{min}} RC_n^2}, \left\| \sum_{ij} A_{ij} \otimes |ij\rangle \langle ij| \right\|_{M_n \otimes_{\text{min}} M_n}, \right\}.$$(16)

We can also define the intersection of these two operator spaces $RC_n = R_n \cap C_n$, where given two operator spaces $E, F$ [56, page 55]

$$\| \cdot \|_{M_n \otimes_{\text{min}} E \cap F} = \max \{ \| \cdot \|_{M_n \otimes_{\text{min}} E}, \| \cdot \|_{M_n \otimes_{\text{min}} F} \}.$$
The first estimate is trivial and the second one can be easily derived by applying the following isometric identifications [29 page 163]

\[ R_n \otimes_{\min} R_n = R_n^2, \quad C_n \otimes_{\min} C_n = C_n^2, \quad C_n \otimes_{\min} R_n = M_n \]

and decomposing \((R_n \cap C_n) \otimes_{\min} (R_n \cap C_n) = (R_n \otimes_{\min} R_n) \cap (R_n \otimes_{\min} C_n) \cap (C_n \otimes_{\min} R_n) \cap (C_n \otimes_{\min} C_n)\) [59 page 55].

With [16] it is trivial to verify that

**Lemma 13.**

\[
\left\| \sum_{ij=1}^N |i\rangle \langle j| \otimes |ij\rangle \right\|_{M_N(RC_{N^2})} = \sqrt{N}.
\]

Moreover, we have the canonical completely isometric identifications

\[ R_n^* = C_n, \quad C_n^* = R_n, \]

and the formal identities \(R_n \longrightarrow RC_n^*, C_n \longrightarrow RC_n^\ast\) are completely contractive.

The connection with Theorem [3] will be made by the following non-commutative Khintchine’s inequality, proved by Lust-Picard and Pisier in [42] (see also [56], Sec. 9.8).

Before stating it, we need to give an alternative view of the Rademacher functions. Given the group of signs \(D_n = \{-1, 1\}^n\) and the normalized Haar measure on it \(\mu_n\), we define the \(i\)-th Rademacher function \(\epsilon_i : D_n \longrightarrow \mathbb{R}\) as the \(i\)-th coordinate function. If we call \(E_n = \text{span}\{\epsilon_i : 1 \leq i \leq n\} \subset L_2(D_n, \mu_n) = \ell_2^m\) (where \(\ell_2^m = (\mathbb{C}^m, \|\cdot\|_2)\)) then

**Theorem 14** (Lust-Picard/Pisier). The canonical identity map \(id : RC_n^* \longrightarrow E_n\) given by \(|i\rangle \mapsto \epsilon_i\) verifies that \(\|id\|_cb \|id^{-1}\|_cb \leq C\), where \(C\) is some universal constant, and the operator space structure on \(\ell_2^m\) is determined by \(\ell_1^m = (\ell_2^m)^*\).

Among all possible operator space structures for a finite dimensional Hilbert space \(\ell_2^m\), there is one that is the minimal in the sense that every bounded operator with range \(\min(\ell_2^m)\) is always completely bounded. This is exactly the operator space structure inherited from the embedding \(\ell_2^m \longrightarrow \ell_{\infty}(S^{m-1})\) given by \(|i\rangle \mapsto f_i\) where \(f_i(\phi) = \langle \phi |i\rangle\) for every \(|\phi\rangle\) in the unit sphere \(S^{m-1}\). There are some properties we will need about \(\min(\ell_2^m)\). The first one is that \(\min(\ell_2^m)\) is a 1-exact operator space in the following sense ([56], Chap. 17):

An operator space \(E\) is called \(\lambda\)-exact if, given any \(C^*\)-algebra \(A\) and any (closed two-sided) ideal \(\mathcal{I} \subset A\), the complete contractive map \(Q : \ell_2^m \otimes_{\min} \mathcal{I} \longrightarrow \ell_2^m \otimes_{\min} \mathcal{I}\) verifies that \(\|Q^{-1}\| \leq \lambda\). In particular, for \(\min(\ell_2^m)\), \(Q\) is a complete isometry.

Moreover, for any operator space \(E\), \(E \otimes_{\min} \min(\ell_2^m) = E \otimes \ell_2^m\) as Banach spaces. With this and [16] one can finally obtain

**Lemma 15.**

\[
\left\| \sum_{ij} |i\rangle \otimes |ij\rangle \right\|_{RC_n^\ast \otimes_{\min} \min(\ell_2^m)} \leq 1
\]

**Random matrices and Wassermann’s construction**

We start with the following application of Chevet’s inequality. Many of the ideas behind the proof come from the seminal work [33 Chapter V]. We essentially follow here [36] which is only available on a preprint server. Therefore we include a complete proof of the statement for convenience of the reader.

**Lemma 16.** Let \(n, N \in \mathbb{N}\) and \(U_N^n\) the \(n\)-fold product of the unitary group equipped with the normalized Haar measure. Then

\[
\mathbb{E} \sup_{\sum_{i=1}^n \lambda_i \leq 1} \left\| \sum_{i=1}^n \lambda_i U_i \right\|_{M_N} \leq 32\pi(1 + \sqrt{\frac{n}{4N}}).
\]
Proof. We recall Chevet’s inequality. For Banach spaces $E, F$, \[33\] Theorem 43.1]

\[
\mathbb{E} \left[ g_{s,t} x_s \otimes y_t \right]_{E \otimes_F} \leq b \left[ (x_s)_s \right]_2^2 \mathbb{E} \left[ g_t y_t \right] + b \left[ (y_t)_t \right]_2^2 \mathbb{E} \left[ g_s x_s \right]_E .
\] (17)

Here $g_{s,t}$ are independent normalized real gaussian random variables, $b = 1$ if the spaces are real whereas $b = 4$ if they are complex, and we recall that

\[
\left\| (x_s)_s \right\|_2^2 = \sup \left\{ \sum_s \left| x^*(x_s) \right|^2 \right\}^{1/2} | x^* \in E^*, \| x^* \| \leq 1 \} .
\]

Let us apply this twice to get

\[
\mathbb{E} \left[ \sum_{i=1}^n \sum_{k,l=1}^N g_{i,k} \ | i \rangle \otimes | k \rangle \otimes \pi \right]_{\ell_2^N \otimes \ell_2^N}
\]

\[
\leq 4 \left[ (i)_i \right]_2^2 \mathbb{E} \left[ \sum_{k,l} g_{i,k} \ | k \rangle \otimes \pi \right]_{\ell_2^N \otimes \ell_2^N} + 4 \mathbb{E} \left[ \sum_{i=1}^n g_{i,k} \ | k \rangle \otimes \pi \right]_{\ell_2^N \otimes \ell_2^N}
\]

\[
\leq 8 \mathbb{E} \left[ \sum_{k=1}^N g_{i,k} \right]_2^2 + 4 \sqrt{n} \leq 8 \sqrt{N} + 4 \sqrt{n} .
\]

In order to transform this to unitaries we replace $g_{i,k}$ by complex gaussians $\tilde{g}_{i,k} = \frac{g_{i,k} + i b_{i,k}}{\sqrt{2}}$. This gives an additional factor $\sqrt{2}$. Then, following \[36\] Lemma 3.2.1.5, we obtain (see below for the details)

\[
1 \mathbb{E} \left[ \sum_{j,k} \tilde{g}_{j,k} \ | j \rangle \langle k | \right]_{\ell_2^N \otimes \ell_2^N} \geq \frac{N^{3/2}}{\pi \sqrt{2}} .
\] (18)

Finally, we have $\mathbb{E} \left[ \sum_{j,k} \tilde{g}_{j,k} \ | j \rangle \langle k | \right]_{\ell_2^N \otimes \ell_2^N} \geq \frac{N^{3/2}}{\pi}$. To see this it is enough to show that for real gaussians and real Hilbert spaces $\ell_2^N$ we get

\[
\mathbb{E} \left[ \sum_{j,k} g_{j,k} \ | j \rangle \langle k | \right]_{\ell_2^N \otimes \ell_2^N} \geq \frac{N^{3/2}}{\pi} .
\]

Recall from above the notation $D_n = \{ -1, 1 \}^n$, $\mu_n$ the Haar measure on $D_n$ and $\epsilon_i$ the i-th Rademacher function. It is a simple exercise \[22\] Section 8.7 to verify that

\[
\mathbb{E} \left[ \left( \sum_{j,k} | g_{j,k} |^2 \right)^{1/2} \right] = \int_{\Omega} \left[ \sum_{j,k} g_{j,k}(\omega) \langle j | \langle k | \right]_{\ell_2^N \otimes \ell_2^N} d\mu(\omega)
\]

\[
\geq \sqrt{2 \pi} \int_{\Omega} \left[ \sum_{j,k} \epsilon_j(s) \langle j | \langle k | \right]_{\ell_2^N \otimes \ell_2^N} d\mu_N(s) = \sqrt{2 \pi} N .
\]

Using the duality $(\ell_2^N \otimes \ell_2^N)^* = \ell_2^N \otimes_{\pi} \ell_2^N$ and Hölder’s inequality this implies

\[
\sqrt{2 \pi} N \leq \mathbb{E} \left[ \left( \sum_{j,k} | g_{j,k} |^2 \right)^{1/2} \right] = \mathbb{E} \left[ \left( \sum_{j,k} g_{j,k} \ | j \rangle \langle k | \sum_{s,t} g_{s,t} | s \rangle \langle t | \right) \right]^{1/2}
\]

\[
\leq \left( \mathbb{E} \left[ \sum_{j,k} g_{j,k} \ | j \rangle \langle k | \right]_{\ell_2^N \otimes \ell_2^N} \right)^{1/2} \left( \mathbb{E} \left[ \sum_{j,k} g_{j,k} \ | j \rangle \langle k | \right]_{\ell_2^N \otimes \ell_2^N} \right)^{1/2} .
\]

Now, using Chevet’s inequality again, we know that $\left( \mathbb{E} \left[ \sum_{j,k} g_{j,k} \ | j \rangle \langle k | \right]_{\ell_2^N \otimes \ell_2^N} \right)^{1/2} \leq \sqrt{2N}$. Thus we have

\[
\mathbb{E} \left[ \sum_{j,k} g_{j,k} \ | j \rangle \langle k | \right]_{\ell_2^N \otimes \ell_2^N} \geq \frac{1}{\pi} N^{3/2} .
\]
So it only remains to the first inequality in (18). We include the argument given in [36, Lemma 3.2.1.5] for completeness. Let \((U_i)_{i=1}^\infty \subset U_N\) be a sequence of unitary matrices. We consider left multiplication \(L\) with respect to block diagonal of \(U_i\)’s, namely \(L: \mathbb{C}^{nN^2} \longrightarrow \mathbb{C}^{nN^2}\) defined by

\[(x^i_{jk})_{jk} \longmapsto (U_i \circ (x^i_{jk})_{jk}), \quad \forall i\]
as well as the corresponding right multiplication. They are unitary operations on \(\mathbb{C}^{nN^2}\) and therefore leave the complex gaussian density invariant.

Given a sequence of random matrices \(G^i(\omega)\) with independent normalized complex gaussian entries, that is \(G^i_{jk}(\omega) = \tilde{g}^i_{jk}(\omega)\), we denote by \(\tau^i(\omega)\) the sequence of singular values of \(G^i(\omega)\), in the sense that there are unitaries \(U^i(\omega), V^i(\omega)\) with

\[G^i(\omega) = U^i(\omega)D_{\tau^i(\omega)}V^i(\omega)\]

We denote by \(\Pi\) the Haar measure on the group \(G\) of sequences of permutations \(G = (Perm\{1, \cdots, N\})^n\) and \(M_\pi\) the permutation matrix \(M_\pi(i) = |\pi(i)|\). For \(i = 1, \cdots, n\) and a diagonal operator \(D_{\tau^i}\), we have

\[\int_G M_\pi D_{\tau^i} M_\pi^{-1} \, d\Pi = (\frac{1}{N} \sum_i \tau^i) i d\mathbb{C}^N\]

Now, let \(C \subset \mathbb{C}^{nN^2}\) be a finite set. Calling \(\mu\) to the Haar measure in \(U_N^\infty\) we get

\[
\int \sup_{ij \in C} \left| \sum_{ij \in C} x_{ij} \tilde{g}^i_{jk}(\omega) \right| d\mathbb{P}(\omega) = \int U_N^\infty \times U_N^\infty \int \sup_{ij \in C} \left| \sum_{ij} x_{ij} (U^i U^i(\omega) D_{\tau^i(\omega)} V^i(\omega) V^i(\omega))_{jk} \right| d\mathbb{P}(\omega) d\mu d\mu
\]

By the invariance of the Haar measure we can write further

\[
\geq \int U_N^\infty \times U_N^\infty \left( \sup_{ij \in C} \left| \sum_{ij \in C} x_{ij} (U^i M_\pi D_{\tau^i(\omega)} M_\pi^{-1} V^i)_{jk} \right| d\mu d\mu d\mathbb{P}(\omega) \right)
\]

\[
\geq \int U_N^\infty \left( \frac{1}{N} \sum_i \tau^i(\omega) d\mathbb{P}(\omega) \right) \int U_N^\infty \left( \sup_{ij \in C} \left| \sum_{ij} x_{ij} (U^i V^i)_{jk} \right| d\mu d\mu \right)
\]

Now, since \(\int \frac{1}{N} \sum_j \tau^i_j(\omega) d\mathbb{P}(\omega) = \frac{1}{N} E\|\sum_j \tilde{g}^i_j \|_{2N^2}\), and taking \(C\) approaching the unit ball of \((\ell_2^N \otimes \varepsilon, \ell_2^N)\), we get (18).

We will use a theorem of Voiculescu in order to obtain a state of the form of Theorem 3 (defined by random unitary matrices). We will need to define some previous concepts.

For a countable discrete group we recall that the left regular representation \(\lambda: G \rightarrow B(\ell_2(G))\) is given by \(\lambda(g)\delta_h = \delta_{gh}\). Here \((\delta_h)\) stands for the unit vector basis in \(\ell_2(G)\). Then \(C_{red}(G)\), the norm closure of the linear span of \(\lambda(G)\), is called the reduced \(C^*\)-algebra of \(G\). The reduced \(C^*\)-algebra sits in the von Neumann algebra \(VN(G) = \lambda(G)^{\prime\prime}\). The normal trace \(\tau\) on \(VN(G)\) is given by \(\tau(x) = \langle \delta_e, x\delta_e \rangle\).

\(\square\)
For the free group $F_n$ in $n$ generators $g_1, \ldots, g_n$, the reduced $C^*$-algebra can be realized by random unitaries in the following sense: Let $(U_N)_{N=1}^\infty$ be random unitaries in $\prod_N U_N^\infty$, endowed with the Haar measure and $\tau_N$ the normalized trace on $U_N$ ($\tau_N(x) = \frac{1}{N} \text{tr}_N(x)$ for each $N$. According to [69 Theorem 4.3.3], we have that
\[
\lim_{N} \tau_N(U_{N,1}^{\epsilon_1} \cdots U_{N,m}^{\epsilon_m}) = \tau(\lambda(g_1)^{\epsilon_1} \cdots \lambda(g_n)^{\epsilon_n}) \tag{19}
\]
holds almost everywhere, for every string $(i_1, \ldots, i_m) \in \{1, \ldots, n\}^m$ and $\epsilon_j = \pm 1$. Here $\tau$ is the normalized trace on the von Neumann algebra $\lambda(F_n)^\prime\prime$. This means that the right hand expression is 1 if and only if $g_1^{\epsilon_1} \cdots g_n^{\epsilon_n}$ is the trivial word $e$ (after cancelation). In all the other cases, we obtain 0. We will use this result in a more quantitative way as follows:

We define the set $\Omega := \{\omega = \{a_1, \cdots, a_k\}| k \in \mathbb{N}, 1 \notin \{a_1, \cdots, a_k\} \subset F_n\}$. Given $1 \neq a \in F_n$, Voiculescu’s theorem [69 Theorem 4.3.3] tells us that
\[
\lim_{N} \mu_N(\{(U_1, \cdots, U_n)| \tau_N(\pi_{U_1} \cdots U_n(a)) < \frac{1}{k}\}) = 1,
\]
where we call $\pi_{U_1} \cdots U_n : F_n \rightarrow M_N$ to the representation of $F_n$ uniquely determined by $g_i \rightarrow U_i$, $i = 1, \cdots, n$. Given $\omega = \{a_1, \cdots, a_k\} \in \Omega$ of cardinality $k$, we deduce the existence of $N_\omega$ such that
\[
\mu_{N_\omega}(\{(U_1, \cdots, U_n)| \tau_{N_\omega}(\pi_{U_1} \cdots U_n(a_i)) < \frac{1}{k} \forall i = 1, \cdots, k\}) > \frac{1}{2}. \tag{20}
\]

Now, we know by Lemma [16] that
\[
E \sup_{\sum |\lambda|^2 \leq 1} \left\| \sum_{i=1}^n \lambda U_i \right\|_{M_{N_\omega}} \leq 32\pi(1 + \sqrt{\frac{n}{4N_\omega}}). \tag{21}
\]

As a consequence of Chebychev’s inequality, for every $\omega \in \Omega$ there exists a sequence $(U_N)_{N=1}^\infty \in U_N^\infty$ which satisfies both (20) and (21) (multiplying by 2 the bound of (21)). These sequences of random unitary matrices will be crucial in our construction and will be fixed from now on.

We simplify the notation a bit more: For every $\omega \in \Omega$ we call $\pi_\omega$ to $\pi_{U_{N_\omega,1} \cdots U_{N_\omega,n}}$, and $\tau_\omega : M_{N_\omega} \rightarrow \mathbb{C}$ to the normalized trace $\tau_\omega(x) = \tau_{N_\omega}(x)$.

We follow now a construction of Wassermann [71] to obtain a representation of the reduced $C^*$-algebra $C_{red}(F_n)$. We fix an ultrafilter $U$ on $\Omega$ refining the sets
\[
\Omega_{\omega = \{a_1, \cdots, a_k\}} := \{\{b_1, \cdots, b_n\} \subset F_n| k \leq n, \omega \subseteq \{b_1, \cdots, b_n\}\}.
\]

Then, we have that for $a \neq 1$,
\[
\lim_{U} \tau_\omega(\pi_\omega(a)) = 0. \tag{22}
\]

We consider the space $\ell_\infty(\Omega, M_{N_\omega})$, and we define the (closed two-side) ideal
\[
\mathcal{I} = \{\{x_\omega\}_\omega \in \ell_\infty(\Omega, M_{N_\omega})| \lim_U \tau_\omega(x_\omega^U, x_\omega) = 0\}.
\]

We also consider the quotient $M_U = \ell_\infty(\Omega, M_{N_\omega})/\mathcal{I}$, which is a finite von Neumann algebra.

Finally, we consider the group representation $\pi : F_n \rightarrow M_U$, defined by
\[
\pi(a) = (\pi_\omega(a))_\omega + \mathcal{I}_U.
\]

Remark 17. It is trivial to check that we can do the same construction taking $\pi_\omega : F_n \rightarrow M_{N_\omega}$, defined by $\pi_\omega(g_i) = U_{N_\omega,i}$.

This construction was done in [71 Sec. 1]. Following this work, and using the crucial property (22), the next theorem follows directly

Theorem 18 (Wassermann). $\pi$ extends to an injective $^*$-homomorphism on $\lambda(F_n)^\prime\prime$, which we also call $\pi$. 

Following the same argument, we obtain a result for the product $F_n^2 = F_n \times F_n$ of the free group. Here we use $\ell_\infty(\Omega, M_{N_\omega} \otimes M_{N_\tau})$ and the ideal $I_f^2 = \{(x_\omega) : \text{lim}_n \tau_{N_\omega}(x_{\omega}^n) = 0\}$ and we write $M_f^2 = \ell_\infty(\Omega, M_{N_\omega} \otimes M_{N_\tau})/I_f^2$ and $\tau_f^2$ for the corresponding trace $\tau_f^2(x_\omega) = \tau_{N_\omega}(x_{\omega}^1)$.

As before, we define $\pi^2 : F_n \times F_n \to M_f^2$ by

$$\pi^2(a_1, a_2) = (\pi_\omega(a_1) \otimes \pi_\omega(a_2))_\omega + I_f^2,$$

and again, using that

$$\lim_{t \to \infty} \tau_f^2((\pi_\omega(a_1) \otimes \pi_\omega(a_2))) = \lim_{t \to \infty} \tau_\omega(\pi_\omega(a_1))\tau_\omega(\pi_\omega(a_2)) = \delta_{a_1,1}\delta_{a_2,1},$$

we can get the analogue of Wassermann’s result:

**Theorem 19.** $\pi^2$ extends to an injective $^\ast$-homomorphism between $(F_n \times F_n)^\ast$ and $M_f^2$, which we also call $\pi^2$.

The next proposition will be crucial in the proof of the main theorem.

**Proposition 20.** There exist matrices $T_{ii'}^{N_\omega} \in M_{N_2}$ such that, if we define $S_{ii'}^{N_\omega} = U_{N_\omega,i} \otimes U_{N_\omega,i'} + T_{ii'}^{N_\omega}$, we have

$$\sup \left\{ \sum_{i'j'k'} a_{ii'}b_{jj'}c_{kk'}(kk')\left| S_{ii'}^{N_\omega}\right| jj' \right\} = \lim_{t \to \infty} \tau_f^2(U^T_{N_\omega,i} \otimes U^T_{N_\omega,i'}S_{hh'}^{N_\omega}) = \delta_{i,h}\delta_{ii'}\delta_{jj'}. $$

**Proof.** We call $id : RC_n \to C_{red}(F_n)$ (resp. $id^2 : RC_n^2 \to C_{red}(F_n \times F_n)$) to $id(|i|) = g_i$ (resp. $id^2(|ii|) = (g_i, g_j)$). By [59] Theorem 9.7.1 $\|id\|_{cb} \leq 2$ and then $\|id^2\|_{cb} \leq 4$ (just by tensoring with $\otimes_{\min}$, since $C_{red}(F_n) \otimes_{\min} C_{red}(F_n) \subset C_{red}(F_n \times F_n)$ [59] Chapter 8).

We consider the map $\pi^2id^2 : RC_n^2 \to M_f^2$ and the amplification

$$\pi^2id^2 \otimes \iota_n^2 : RC_n^2 \otimes \min \min(\ell_2^2) \to \ell_\infty(M_{N_\omega} \otimes M_{N_\tau})/I_f^2 \otimes \min \min(\ell_2^2).$$

Using that any $^\ast$-homomorphism (in particular $\pi^2$) is completely contractive, that $\min(\ell_2^2)$ is a 1-exact operator space and Lemma 15 there exists a lifting

$$Z_{N_\omega} = \sum_{ii'} \left( U_{N_\omega,i} \otimes U_{N_\omega,i'} + T_{ii'}^{N_\omega} \right) \otimes |ii'\rangle \in M_{N_2} \otimes \min \min(\ell_2^2)$$

with $T_{ii'}^{N_\omega} \in I_f^2$ and $\sup \|Z_{N_\omega}\| \leq 5$. Now we use that $M_{N_2} \otimes \min \min(\ell_2^2) = M_{N_2} \otimes \ell_2^2$ to show that

$$\|Z_{N_\omega}\| = \sup \left\{ \sum_{i'j'k'} a_{ii'}b_{jj'}c_{kk'}(kk')\left| S_{ii'}^{N_\omega}\right| jj' \right\} = \sum_{i'j'k'} |a_{ii'}|^2 \leq 1, \sum_{j'k'} |b_{jj'}|^2 \leq 1, \sum_{kk'} |c_{kk'}|^2 \leq 1 \right\} \leq 5. $$

To conclude it is enough to show that

$$\lim_{t \to \infty} \tau_f^2((U^T_{N_\omega,i} \otimes U^T_{N_\omega,i'})\langle U_{N_\omega,h} \otimes U_{N_\omega,h'} + T_{hh'}^{N_\omega}) = \delta_{i,h}\delta_{ii'}\delta_{jj'}. $$

(23)

Indeed, by [22] we have

$$\lim_{t \to \infty} \tau_f^2((U^T_{N_\omega,i} \otimes U^T_{N_\omega,i'})\langle U_{N_\omega,h} \otimes U_{N_\omega,h'}) = \delta_{i,h}\delta_{ii'}\delta_{jj'}).$$

Moreover, since $(T_{hh'}^{N_\omega}) \in I_f^2$ we deduce

$$\lim_{t \to \infty} \tau_f^2((U^T_{N_\omega,i} \otimes U^T_{N_\omega,i'})T_{hh'}^{N_\omega})) \leq \lim_{t \to \infty} \tau_f^2((U^T_{N_\omega,i} \otimes U^T_{N_\omega,i'})\langle U_{N_\omega,i} \otimes U_{N_\omega,i'})^{1/2}\tau_{N_\omega}^2((T_{hh'}^{N_\omega})^{1/2}(T_{hh'}^{N_\omega}))^{1/2}) = \lim_{t \to \infty} \tau_f^2((T_{hh'}^{N_\omega})^{1/2}(T_{hh'}^{N_\omega}))^{1/2} = 0. $$

\[\square\]

**Remark 21.** The operators $T_{ii'}^{N_\omega}$ are highly non-trivial. This can be seen by noticing that $\|\sum_{i=1}^n U_{N,i} \otimes U_{N,i} + T_{ii'}^{N_\omega}\|_{M_{N_2}} = n$. This is by factor $\sqrt{n}$ larger than $\|\sum_{i=1}^n U_{N,i} \otimes U_{N,i} + T_{ii'}^{N_\omega}\|_{M_{N_2}}$. guaranteed from the Wassermann lifting.
Proof of the result

We define the (unnormalized) state $|\psi_{N_\omega}\rangle = \frac{1}{\sqrt{n\omega}} \sum_{1 \leq i \leq n} \sum_{1 \leq j,k \leq N_\omega} \langle j | U_{N_\omega,i}^\dagger | k \rangle | i \rangle$. We know that these matrices verify the estimate from Lemma 14 and hence

$$\| \langle \psi_{N_\omega} | ||_{L_2^2 \otimes M_{N_\omega}} \leq \frac{1}{\sqrt{n\omega}}$$

which means that $\langle \psi_{N_\omega} | \psi_{N_\omega} \rangle \geq 1$.

We define the trilinear form $v_{N_\omega} : \ell_2^{n^2} \times \ell_2^{N_\omega^2} \times \ell_2^{N_\omega^2} \rightarrow \mathbb{C}$ by

$$v_{N_\omega}([ii'], [jj'], [kk']) = \langle kk' | S_{ii'} jj' \rangle.$$

Thanks to Proposition 20 $\| v_{N_\omega} \| \leq 5$. If we call $q = id^*$ where $id$ is the map given in Theorem 14 we define $T$ via the diagram

$$
\begin{array}{ccc}
\ell_2^{n^2} \times \ell_2^{N_\omega^2} \times \ell_2^{N_\omega^2} & \rightarrow & \mathbb{C} \\
q \otimes q \otimes q & & \\
\end{array}
$$

It is clear that $\| T \| \leq 1$. Moreover, since $q : \ell_2^M \rightarrow RC_m$ is a complete quotient (Theorem 14), there exist $b \in M_n(\ell_2^{n^2})$ and $\hat{b} \in M_{N_\omega}(\ell_2^{N_\omega^2})$ such that

$$(\mathbb{1}_n \otimes q)(b) = \frac{1}{\sqrt{n}} \sum_{i,i'=1}^n [i \langle i' | \otimes | ii' \rangle$$

$$(\mathbb{1}_{N_\omega} \otimes q)(\hat{b}) = \frac{1}{\sqrt{N_\omega}} \sum_{j,j'=1}^{N_\omega} [j \langle j' | \otimes | jj' \rangle$$

$$\| b \|, \| \hat{b} \| \leq 1 \quad \text{(by Lemma 13)}$$

It remains to be proven that (for some $N_\omega$)

$$\left| \langle \psi_{N_\omega} | T_{n,N_\omega,N_\omega} (b, \hat{b}, \hat{b}) | \psi_{N_\omega} \rangle \right| \geq \sqrt{n}. $$

To see this we notice

$$\left| \langle \psi_{N_\omega} | T_{n,N_\omega,N_\omega} (b, \hat{b}, \hat{b}) | \psi_{N_\omega} \rangle \right| = \frac{1}{N_\omega \sqrt{n}} \left| \langle \psi_{N_\omega} | \left( \sum_{ii'jj'kk'} v_{N_\omega}([ii'], [jj'], [kk']) [ii'] \langle jj' | \otimes | jj' \rangle \langle kk' | \right) | \psi_{N_\omega} \rangle \right| =$$

$$\frac{1}{N_\omega^2 n \sqrt{n}} \left| \sum_{ii'jj'kk'} (kk' | S_{ii'} jj' \rangle \langle jj' | U_{N_\omega,i}^\dagger | k \rangle \langle k | U_{N_\omega,i}^\dagger | j \rangle \langle j | \right) = \frac{1}{N_\omega^2 n \sqrt{n}} \left| \sum_{ii'} \text{tr}(U_{N_\omega,i}^T \otimes U_{N_\omega,i}^\dagger S_{ii'}^N h_{ii'} \rangle \langle hh' |) \right| \rightarrow \sqrt{n},$$

since, by Proposition 20

$$\lim_{n \rightarrow \infty} \sum_{ii',hh'} \tau_{N_\omega^2} (U_{N_\omega,i}^T \otimes U_{N_\omega,i}^\dagger S_{hh'}^N | ii' \rangle \langle hh' |) = id_{\ell_2^2}.$$ 

The result follows trivially.

The optimality part is a trivial consequence of the following
Proposition 22. For any $N$ and any linear map $v : \ell_\infty^N \longrightarrow \ell_1^N \otimes \ell_1^N$, if we call $v_n$ to the amplification $v_n = \mathbb{1}_n \otimes v : M_n(\ell_\infty^N) \longrightarrow M_n(\ell_1^N \otimes \min \ell_1^N)$, then
\[
\|v_n\| \leq \sqrt{N}\|v\|.
\]

Proof. We recall that $E_n$ is the linear span of the first $n$ Rademacher functions in $L_1(D_n)$. $F_n$ will be $E_n \otimes E_n \subset L_1(D_n \times D_n)$. By the classical Khintchine's inequalities (see for instance [22], Sec. 8.5), we have that
\[
\left( \sum_{ij} |\alpha_{ij}|^2 \right)^{\frac{1}{2}} \lesssim \sum_{ij} \alpha_{ij} \epsilon_i \epsilon_j \|f\|_{L_1(D_n \times D_n)}.
\]
Hence, the norm of the identity $id : F_n \longrightarrow S_2^n (\epsilon_i \epsilon_j' \mapsto |i\rangle \langle j|)$ is $\leq 1$ and therefore (recall that $\|\cdot\|_{S_2^n} \leq \sqrt{n} \|\cdot\|_{M_n}$) the norm of the adjoint map $id : M_n \longrightarrow F_n^* = \frac{L_\infty(D_n \times D_n)}{P_n}$ is $\leq \sqrt{n}$. Using that the formal identities $R_n \longrightarrow RC_n^*$, $C_n \longrightarrow RC_n^*$ are completely contractive and Theorem 14, we get that the identity $id : R_n \otimes^\epsilon C_n \longrightarrow E_n \otimes E_n \subset L_1(D_n) \otimes L_1(D_n) = L_1(D_n \times D_n)$ has completely bounded norm $\leq 1$. Then the adjoint map $\|id : F_n \longrightarrow M_n\|_{cb} \leq 1$.

Let us take now $x = \sum_{ij} |i\rangle \langle j| \otimes x_{ij} \in M_n(\ell_\infty^N) = M_n \otimes \ell_\infty^N$ with norm $\leq 1$. There exists a function $f \in L_\infty(D_n \times D_n)(\ell_\infty^N)$ such that $\|f\| \leq \sqrt{n}$ and
\[
x_{ij} = \int_{D_n \times D_n} \epsilon_i \epsilon_j' f(\epsilon, \epsilon') d\mu_n(\epsilon) d\mu_n(\epsilon').
\]
For that we have used that if $Q : X \longrightarrow Y$ is an isometric quotient, then $Q \otimes id : X \otimes \ell_\infty^N \longrightarrow Y \otimes \ell_\infty^N$ is also an isometric quotient (see for instance [22], Sec. 4.4).

If we denote $g = id \otimes v(f) \in L_\infty(D_n \times D_n)(\ell_1^N \otimes \ell_1^N)$, then $\|g\| \leq \sqrt{n}\|v\|$ and
\[
v(x_{ij}) = \int_{D_n \times D_n} \epsilon_i \epsilon_j' g(\epsilon, \epsilon') d\mu_n(\epsilon) d\mu_n(\epsilon').
\]
If $Q : L_\infty(D_n \times D_n) \longrightarrow F_n^* = \frac{L_\infty(D_n \times D_n)}{P_n}$ is the canonical quotient map, the composition $idQ : L_\infty(D_n \times D_n) \longrightarrow M_n$ (given by $idQ(h) = \sum_{ij} (\int \epsilon \epsilon_j' h |i\rangle \langle j|$)) has completely bounded norm $\leq 1$ and then
\[
\|v_n(x)\|_{M_n(\ell_1^N \otimes \min \ell_1^N)} = \|idQ \otimes \mathbb{1}_n(\ell_1^N \otimes \ell_1^N)(g)\|_{M_n(\ell_1^N \otimes \min \ell_1^N)} \leq \|idQ\|_{cb}\|g\|_{L_\infty(D_n \times D_n) \otimes (\ell_1^N \otimes \min \ell_1^N)} \leq \sqrt{n}\|v\|,
\]
since, by Grothendieck’s theorem, $\ell_1^N \otimes \min \ell_1^N \simeq \ell_1^N \otimes \ell_1^N$ (see Section [III]).

\[

\]

VI. CONCLUSION

We have shown that some tripartite quantum states, constructed in a random way, can lead to arbitrarily large violations of Bell inequalities. Moreover, and contrary to what happens with other measures of entanglement, the GHZ state does not share this extreme behavior. Apart from the interest of the results (in particular we answer a long standing open question of Tsirelson) and from the applications that can be derived (see Section [II]), we think that one of the main achievements in the paper is the use of completely new mathematical tools in this context. We hope that the techniques and connections we have established here will provide a better understanding of Bell inequalities in the near future. In this direction we would like to finish with some open problems.

A couple of open questions

We have proven in the text that there are reasonably many states leading to large violations of Bell inequalities, since we have constructed them using random unitaries. However, if we focus on the inequalities (rather than on the states) the picture is much less clear. Apart from seeking for an explicit form (see Remark after Theorem 1) one could ask the following:

Question 1: How many Bell inequalities give large violation?
Following the relations found in this paper, one can formulate this question in the following quantitative way:

**Question 1':** Are the volumes of the unit balls of $ℓ^*_1 ⊗_c ℓ^*_1 ⊗_c ℓ^*_1$ and $ℓ^*_1 ⊗_c ℓ^*_1 ⊗_c ℓ^*_1$ comparable?

Once more Chevet’s inequality gives us the right estimate for the volume of the unit ball of $ℓ^*_1 ⊗_c ℓ^*_1 ⊗_c ℓ^*_1$. So the question can be finally stated as

**Question 1'':** Which is the (asymptotic) volume of the unit ball of $ℓ^*_1 ⊗_c ℓ^*_1 ⊗_c ℓ^*_1$?

Unfortunately, the techniques used in this paper do not seem to help much to tackle this problem, and probably new ideas have to come into play.

Another interesting question arising from the paper is the possibility of giving highly non-local states with a simpler structure than the ones given here. For instance, it would be nice to know if

**Question 2:** Can one find a diagonal state $|ψ⟩ = \sum D_{α} |iii⟩$ giving unbounded violation to a Bell inequality?

We have proven that the GHZ (i.e. $α_i = \frac{1}{√D}$ for every $i$) does not, but, interestingly enough, Question 2 is equivalent to the following completely mathematical question

**Question 2':** Is $S_∞$ (the space of compact operators in a Hilbert space) a Q-algebra with the Schur product?

This question, that was formulated by Varopoulos in 1975 [67], is still open, though there has been some progress towards its solution [40, 51]. A nice exposition about Q-algebras can be found in [25, Chapter 18]. We review here the basics to connect Questions 2 and 2'.

A Q-algebra is defined as a commutative Banach algebra isomorphic to a quotient algebra of a uniform algebra, where a uniform algebra is simply a closed subalgebra of the algebra of continuous functions $C(K)$ for some compact Hausdorff space $K$. For a brief exposition of the history and importance of this kind of algebras we refer the reader to [25, Chapter 18, Notes and Remarks]. A very important step in the understanding of these algebras was made by Davie [20], by proving the following criterion

**Theorem 23.** A commutative Banach algebra $X$ is a Q-algebra if and only if there is a universal constant $K$ such that

$$\| \sum_{i_1,..,i_N} t_{i_1..i_N} x_{i_1}^1...x_{i_N}^N \|_X \leq K^N \sup_{\|\epsilon_{i_j}^j\|_1=1} \left| \sum_{i_1,..,i_N} t_{i_1..i_N} \epsilon_{i_1}^1...\epsilon_{i_N}^N \right|.$$ 

For every choice of elements $x_{i_j}^j \in X$ with $\|x_{i_j}^j\| \leq 1$.

To be precise this is not exactly the formulation made by Davie, but one can easily obtain it following the reasonings of [25, Prop. 18.6, Thm. 18.7]. Using Theorem 23 we can formalize the relation between Questions 2 and 2'.

**Theorem 24.** $S_∞$ is a Q-algebra if and only if there is a universal constant $K$ such that for any $N$ and any diagonal $N$-partite state $|ψ⟩ = \sum_{i=1}^D \alpha_i |ii...i⟩$, the largest violation that $|ψ⟩$ can induce in a Bell inequality (with an arbitrarily number of dichotomic observables) is bounded by $K^N$.

**Proof.** Let us assume first that $S_∞$ is a Q-algebra. By Theorem 23 for real $t_{i_1..i_N}$ and hermitian $A_{i_j}^j \in M_D \subset S_∞$ with $\|A_{i_j}^j\|_{M_D} \leq 1$ we have that

$$\| \sum_{i_1,..,i_N} t_{i_1..i_N} A_{i_1}^i * \cdots \ast A_{i_N}^i \|_{S_∞} \leq K^N \sup_{\|\epsilon_{i_j}^j\|_1=1} \left| \sum_{i_1,..,i_N} t_{i_1..i_N} \epsilon_{i_1}^1...\epsilon_{i_N}^N \right| \leq (2K)^N \sup_{\epsilon_{i_j}^j=\pm 1} \left| \sum_{i_1,..,i_N} t_{i_1..i_N} \epsilon_{i_1}^1...\epsilon_{i_N}^N \right|,$$

where $*$ means Schur (or Hadamard) product.
We now notice that
\[
\| \sum_{i_1, \ldots, i_N} t_{i_1 \ldots i_N} A_{i_1}^1 \cdots A_{i_N}^N \|_{S_\infty} = \max_{\{r\}} \left| \sum_{i_1, \ldots, i_N} t_{i_1 \ldots i_N} A_{i_1}^1 \cdots A_{i_N}^N \right|_{S_\infty} = \max_{\sum |a_{i,j}|^2=1} \left| \sum_{i_1, \ldots, i_N} t_{i_1 \ldots i_N} \sum_{i,j} a_{i,j} \langle ii \cdots i | A_{i_1}^1 \otimes \cdots \otimes A_{i_N}^N | jj \cdots j \rangle \right| = \max_{|\psi\rangle \text{ diagonal}} \left| \sum_{i_1, \ldots, i_N} t_{i_1 \ldots i_N} |\psi\rangle A_{i_1}^1 \otimes \cdots \otimes A_{i_N}^N \langle \psi| \right|.
\]

For the other implication we assume by hypothesis, and using (24), that
\[
\| \sum_{i_1, \ldots, i_N} t_{i_1 \ldots i_N} A_{i_1}^1 \cdots A_{i_N}^N \|_{S_\infty} \leq K^N \sup_{c_{i,j}=\pm 1} \left| \sum_{i_1, \ldots, i_N} t_{i_1 \ldots i_N} c_{i_1}^1 \cdots c_{i_N}^N \right|
\]
for real \( t_{i_1 \ldots i_N} \) and hermitian \( A_{i_j}^j \in M_N \subset S_\infty \) with \( \|A_{i_j}^j\|_{M_N} \leq 1 \). By splitting into real and imaginary part it is easy to obtain (25) for complex \( t_{i_1 \ldots i_N} \) and arbitrary matrices \( A_{i_j}^j \in M_D \) of norm 1 (maybe with a different constant \( K' \)). Since, given any \( \epsilon > 0 \), we can approximate any element \( x \in S_\infty \) of \( \|x\| \leq 1 \) by a matrix \( A \in M_D \) with \( \|A\| \leq 1 \) and \( \|x-A\|_{S_\infty} \leq \epsilon \), we obtain
\[
\sup_{||x_i||^2 \leq 1} \| \sum_{i_1, \ldots, i_N} t_{i_1 \ldots i_N} x_{i_1}^1 \cdots x_{i_N}^N \|_{S_\infty} \leq K^N \sup_{c_{i,j}=\pm 1} \left| \sum_{i_1, \ldots, i_N} t_{i_1 \ldots i_N} c_{i_1}^1 \cdots c_{i_N}^N \right| \leq K^N \sup_{|c_{i,j}|=1} \left| \sum_{i_1, \ldots, i_N} t_{i_1 \ldots i_N} c_{i_1}^1 \cdots c_{i_N}^N \right|,
\]
which finishes the proof of the theorem.

We write \[ \| \rho \|_\pi \geq d^2 \] since the above expression is exactly the norm of \( T \) as a \( N \)-linear form from \( \mathbb{R}^D \) equipped with the sup-norm.

**APPENDIX: PROOF OF THEOREM 2**

The aim of this appendix is to show again the advantages of using the theory of tensor norms to tackle some problems on Quantum Information. Here we provide a new proof for Theorem 2. The key point of the proof is the following characterization of separability (32) (see also 52):

**Theorem 25.** A tripartite state \( \rho \) on \( \mathcal{C}^d \otimes \mathcal{C}^d \otimes \mathcal{C}^d \) is separable if and only if it is in the closed unit ball of \( \bigotimes_{j=1}^3 \mathcal{C}^d \).

The following lemma will be crucial.

**Lemma 26.** The identity

\[
\text{id} : \bigotimes_{j=1}^3 \Delta_2 \otimes \pi (\bigotimes_{j=1}^3 \Delta_2) \rightarrow \bigotimes_{j=1}^6 \Delta_2
\]

has norm \( \geq d^2 \), where \( \Delta_2 \) is the usual (Hilbert-Schmidt) tensor norm that makes \( \ell_2^d \otimes \Delta_2 \ell_2^d \).
hold for arbitrarily chosen elements $x_j \in X$:

$$\sum_i \|u(x_i)\| \leq K \sup_{x^* \in X^*, \|x^*\| \leq 1} \sum_i |x^*(x_i)|.$$ 

We can also define the 1-factorable norm of $u$, namely $\gamma_1(u)$, as $\inf \{\|a\|\|b\| : a: X \to \ell^1, b: \ell^1 \to Y \text{ and } u = ba\}$.

Both norms define operator ideals [22] in the sense that they verify the inequalities $\pi_1(uvw) \leq \|u\| \pi_1(v) \|w\|$, $\gamma_1(uvw) \leq \|u\| \gamma_1(v) \|w\|$.

Now, given a finite dimensional Banach space $X$, we can define its Gordon-Lewis constant $\text{gl}(X)$ as the smallest constant $K$ such that $\gamma_1(u) \leq K \pi_1(u)$ for every linear operator $u: X \to \ell^N$.

Proof. (of Lemma 26) In [21] it is proven that the Gordon-Lewis constant $\text{gl}(\otimes^3_{j=1,\Delta_3} \ell^d_2) \simeq d$, which by duality [25, Prop. 17.9] implies $\text{gl}(\otimes^3_{j=1,\pi} \ell^d_2) \simeq d$.

By the ideal property of $\gamma_1$ and $\pi_1$, it can be easily deduced that if $u: X \to Y$ and $v: Y \to X$ are two operators such that $id_X = vu$, then $\text{gl}(X) \leq \|u\|\|v\|\text{gl}(Y)$. Then, since $\text{gl}(\otimes^3_{j=1,\Delta_3} \ell^d_2) \simeq 1$ [25, Cor. 4.12], the norm of the identity $id: \otimes^3_{j=1,\Delta_3} \ell^d_2 \to \otimes^3_{j=1,\pi} \ell^d_2$ has to be $\geq d$. The Lemma is then a consequence of the metric mapping property for the $\pi$ tensor norm (see Section III).

Since the trace class $S^d_1$ can be identified with $\ell^d_2 \otimes_\pi \ell^d_2$, Lemma 26 implies that there exists a $d^3 \times d^3$ matrix $\rho$ such that $\|\rho\|_{S^d_1} = 1$ and $\|\rho\|_\pi \simeq d^3$. Using the Cartesian decomposition $\rho = \text{Re} \rho + i \text{Im} \rho$ one can assume $\rho$ to be hermitian, and then, decomposing again into the positive and negative part, one obtains that $\rho$ can indeed be taken positive, and hence with trace 1. But now, the state $\rho' = pp + (1-p)\frac{1}{d^3}$ verifies that $\|\rho'\|_\pi > 1$ and is therefore entangled for every $p > \frac{2}{1+\|\rho\|_\pi} \simeq \frac{1}{d^3}$. This proves Theorem 2.
