We introduce an operational framework to analyze non-adiabatic Abelian and non-Abelian, cyclic and non-cyclic, geometric phases in open quantum systems. In order to remove the adiabaticity condition, we generalize the theory of dynamical invariants to the context of open systems evolving under arbitrary convolutionless master equations. Geometric phases are then defined through the Jordan canonical form of the dynamical invariant associated with the super-operator that governs the master equation. As a by-product, we provide a sufficient condition for the robustness of the phase against a given decohering process. We illustrate our results by considering a two-level system in a Markovian interaction with the environment, where we show that the non-adiabatic geometric phase acquired by the system can be constructed in such a way that it is robust against both dephasing and spontaneous emission.

I. INTRODUCTION

Geometric phases (GPs) provide a remarkable mechanism for a quantum system to keep the memory of its motion as it evolves in Hilbert-Schmidt space. These phase factors depend only on the geometry of the path traversed by the system during its evolution. In the context of quantum mechanics, GPs were first obtained by Berry [1], who considered the adiabatic cyclic evolution of a non-degenerate quantum system isolated from the contact with a quantum environment. After the seminal work by Berry, the concept of GPs has been generalized in a number of distinct directions, e.g., degenerate systems [2], non-adiabatic [3] and non-cyclic evolutions [4], etc. Besides its conceptual importance in quantum mechanics, GPs have also attracted an increasing attention since their proposal as a tool to achieve fault tolerance in quantum information processing [5,6].

Motivated by the applications in quantum information, a great effort has been devoted to analyzing GPs in open quantum systems, i.e., quantum systems subjected to decoherence due to its interaction with a quantum environment [7]. The assumption that a quantum system is closed is always an idealization and therefore, in order to implement realistic applications in quantum mechanics, we should be able to estimate the effects of the surrounding environment on the dynamics of the system. For a number of physical phenomena, the open system can be conveniently described by a convolutionless (local) master equation after the degrees of freedom of the environment are traced out [7,8]. In this context, several treatments for GPs acquired by the density operator have been proposed (see, e.g., Refs. [5,10,11,12,13]). Moreover, in the particular case of Markovian interaction with the environment, where the system is described by a master equation in the Lindblad form [14], GPs have also been analyzed through quantum trajectories [15,16,17] (see also Ref. [18] for a further discussion of GPs via stochastic unravelings).

More recently, in the case of adiabatic evolution, Abelian and non-Abelian GPs in open systems have been generally defined in Ref. [19]. This approach was based on an adiabatic approximation previously established for convolutionless master equations [20] (see also Ref. [21] for an application of this adiabatic approximation in adiabatic quantum computation under decoherence and Ref. [22] for an alternative adiabatic approach in weakly coupled open systems). However, although the adiabatic behavior is usually a very welcome feature in theoretical models, it can be unsuitable if decoherence times are small. Therefore, it would be rather desirable to have a general formalism to deal with non-adiabatic GPs for systems under decoherence. In closed systems, a useful tool to remove the adiabaticity constraint of geometric phases [23,24,25,26] is the theory of dynamical invariants [27] to treat time-dependent Hamiltonians. Indeed, dynamical invariants were recently used in a proposal of an interferometric experiment to measure non-adiabatic GPs in cavity quantum electrodynamics [28].

The aim of this work is to generalize the theory of dynamical invariants to the context of open quantum systems and to show how this generalization can be used to establish a general approach for non-adiabatic, Abelian and non-Abelian, cyclic and non-cyclic, GPs acquired by the components of the density operator of a system evolving under a convolutionless master equation (see also a related work in Ref. [29], which introduced a relationship between GPs and dynamical invariants for a master equation in the Lindblad form). Within our formalism, we will be able to provide a sufficient condition to ensure the robustness of the phase against a given decohering process. As an illustration of our result, we will consider a two-level quantum system (a qubit) interacting with an

*Electronic address: mssarandy@if.ufr.br
†Electronic address: duzzioni@df.ufscar.br
‡Electronic address: miled@ifsc.usp.br
environment through a Lindblad equation. Then, we will find that this system is robust against both dephasing and spontaneous emission. This generalizes the results for the robustness against these decohering processes found in the adiabatic case in Ref. [20]. Furthermore, in the case of spontaneous emission, robustness of the non-adiabatic GP is a new feature of our approach, which should positively impact geometric QC (see, e.g., Ref. [17] for difficulties in the correction of spontaneous emission).

II. DYNAMICAL INVARIANTS IN OPEN SYSTEMS

For a closed quantum system, a dynamical invariant \( I(t) \) is an Hermitian operator which satisfies \[ \frac{d}{dt} I - \frac{1}{i} [H, I] = 0, \] (1) where \( H \) is the Hamiltonian of the system. Dynamical invariants have time-independent eigenvalues, implying therefore that their expectation value is constant, i.e., \( d\langle I(t) \rangle / dt = 0 \).

In order to generalize the concept of a dynamical invariant to the context of open systems, we consider a general open system described by a convolutionless master equation

\[ \dot{\rho} = \mathcal{L}\rho, \]

(2)

where \( \rho(t) \) is the density operator, which can be taken as vector in Hilbert-Schmidt space, and \( \mathcal{L} \) is the (usually non-Hermitian) super-operator which dictates the dynamics of the system. Given an open system governed by \( \mathcal{L}(t) \), we define a dynamical invariant \( I(t) \) as a super-operator which satisfies the equation

\[ \frac{d}{dt} I - [\mathcal{L}, I] = 0. \]

(3)

Similarly to the case of closed systems, the eigenvalues of the super-operator \( I(t) \) will be shown to be time-independent, as expected for a dynamical invariant. However, note that Eq. (3) does not uniquely determine \( I(t) \) nor ensures that such a super-operator exists. The success of our approach will rely therefore on the possibility of constructing non-trivial (time-dependent) dynamical invariants, which can fortunately be found in a number of interesting examples.

The super-operator \( I(t) \) is in general non-Hermitian, which means that it will not always exhibit a basis of eigenstates. However we can construct a right basis \( \{ |D^{(i)}_{\alpha} \rangle \} \) and a left basis \( \{ \langle E^{(i)}_{\alpha} | \} \) in Hilbert-Schmidt space based on the Jordan canonical form of \( I(t) \) [20]. Here, the double-ket notation is used to emphasize that these vectors are defined in the space state of linear operators instead of the ordinary Hilbert space. This construction is analogous to the procedure developed in Ref. [20], but using now the Jordan decomposition of \( I(t) \) rather than \( \mathcal{L}(t) \). It can be shown (see Ref. [20] or Appendix A of Ref. [19]) that left and right basis vectors can always be chosen such that they have the properties

\[ I |D^{(i)}_{\alpha} \rangle = \lambda_{\alpha} |D^{(i)}_{\alpha} \rangle + |D^{(i-1)}_{\alpha} \rangle, \]

(4)

\[ \langle E^{(i)}_{\alpha} | I = \langle E^{(i)}_{\alpha} | \lambda_{\alpha} + \langle E^{(i+1)}_{\alpha} |, \]

(5)

where \( |D^{(i-1)}_{\alpha} \rangle \equiv 0 \) and \( \langle E^{(i+1)}_{\alpha} | \equiv 0 \), with the index \( \alpha \) enumerating each Jordan block and the index \( i \) enumerating the basis vectors inside each Jordan block, with \( i = 0, \ldots, n_{\alpha} - 1 \) (\( n_{\alpha} \) is the dimension of the block \( \alpha \)). Moreover, left and right vectors satisfy the orthonormality condition

\[ \langle E^{(i)}_{\alpha} | |D^{(i)}_{\beta} \rangle = \delta_{\alpha \beta} \delta^{ij}. \]

(6)

The eigenvalues of \( I(t) \) are denoted by \( \lambda_{\alpha} \) and the left and right eigenvectors of \( I(t) \) are denoted by \( |D^{(i)}_{\alpha} \rangle \) and \( \langle E^{(i)}_{\alpha} | \), respectively. Taking the derivative of Eq. (4) with respect to time (denoted by the dot symbol below), we obtain

\[ \dot{I} |D^{(i)}_{\alpha} \rangle + I |D^{(i)}_{\alpha} \rangle = \dot{\lambda}_{\alpha} |D^{(i)}_{\alpha} \rangle + \lambda_{\alpha} |D^{(i+1)}_{\alpha} \rangle + |D^{(i-1)}_{\alpha} \rangle. \]

(7)

Projection of Eq. (7) in \( \langle E^{(j)}_{\beta} | \) yields

\[ \langle E^{(j)}_{\beta} | \dot{I} |D^{(i)}_{\alpha} \rangle = \dot{\lambda}_{\alpha} \delta_{\alpha \beta} \delta^{ij} + \lambda_{\alpha} - \lambda_{\beta} \langle E^{(j)}_{\beta} | \dot{D}^{(i)}_{\alpha} \rangle + \langle E^{(j)}_{\beta} | D^{(i+1)}_{\alpha} \rangle - \langle E^{(j+1)}_{\beta} | D^{(i)}_{\alpha} \rangle. \]

(8)

On the other hand, from the definition of a dynamical invariant, given by Eq. (3), we get

\[ \langle E^{(j)}_{\beta} | \dot{I} |D^{(i)}_{\alpha} \rangle = \lambda_{\alpha} - \lambda_{\beta} \langle E^{(j)}_{\beta} | D^{(i)}_{\alpha} \rangle + \langle E^{(j)}_{\beta} | D^{(i+1)}_{\alpha} \rangle - \langle E^{(j+1)}_{\beta} | D^{(i)}_{\alpha} \rangle \]

(9)

By inserting Eq. (9) into Eq. (8), we obtain

\[ \dot{\lambda}_{\alpha} \delta_{\alpha \beta} \delta^{ij} = (\lambda_{\alpha} - \lambda_{\beta}) \langle E^{(j)}_{\beta} | O |D^{(i)}_{\alpha} \rangle + \langle E^{(j+1)}_{\beta} | O |D^{(i)}_{\alpha} \rangle \]

(10)

where

\[ O \equiv \mathcal{L} - \frac{\partial}{\partial t}. \]

(11)

Let us assume, from now on, that \( n_{\alpha} = 1 \), i.e., the Jordan blocks are one-dimensional (1D). This means that we are assuming that we were able to find a diagonalizable \( I(t) \) (even though it can be non-Hermitian). As we will show below, Abelian GPs will be associated with the situation where \( I(t) \) has non-degenerate 1D Jordan blocks while non-Abelian phases will be associated with the situation where \( I(t) \) displays degenerate 1D Jordan blocks. For multi-dimensional Jordan blocks, we should proceed by a case by case analysis, with no general treatment available.

Therefore, assuming 1D Jordan blocks, we have

\[ \dot{\lambda}_{\alpha} \delta_{\alpha \beta} \delta^{ij} = (\lambda_{\alpha} - \lambda_{\beta}) \langle E^{(j)}_{\beta} | O |D^{(i)}_{\alpha} \rangle, \]

(12)

where, now, the indices \( i \) and \( j \) appearing in both \( \{ |D^{(i)}_{\alpha} \rangle \} \) and \( \{ \langle E^{(j)}_{\beta} | \} \) account for degenerate states, namely, states such that \( \lambda_{\alpha} = \lambda_{\beta} \), whichever \( \alpha \) and \( \beta \). Observe that for \( \alpha = \beta \) and \( i = j \), we obtain \( \dot{\lambda}_{\alpha} = 0 \), which implies that the dynamical invariant has indeed time-independent eigenvalues. Moreover, taking indices \( \alpha \) and \( \beta \) such that \( \lambda_{\alpha} \neq \lambda_{\beta} \), we obtain

\[ \langle E^{(j)}_{\beta} | O |D^{(i)}_{\alpha} \rangle = 0 \quad (\lambda_{\alpha} \neq \lambda_{\beta}). \]

(13)

Eq. (13) provides the fundamental condition that will allow for the definition of non-adiabatic GPs.
III. NON-ADIABATIC GPS VIA DYNAMICAL INVARIANTS

A. Abelian case

Let us assume that the eigenvalues of $\mathcal{I}(t)$ are non-degenerate, i.e., $\lambda_\alpha = \lambda_\beta \Rightarrow \alpha = \beta$. In order to simplify the notation, we will omit the upper index $i$ of the right and left vectors in the Abelian case. Let us take the density operator $\rho$ as a vector in Hilbert-Schmidt space and expand it in the right basis $\{|D_\alpha\rangle\}$

$$|\rho\rangle = \sum \alpha c_\alpha |D_\alpha\rangle$$

(14)

By inserting Eq. (14) into the master equation (2) and projecting it in $\langle\langle \mathcal{E}_\beta |, we obtain

$$\dot{c}_\beta = \sum \alpha c_\alpha \langle\langle \mathcal{E}_\beta | \mathcal{O} | D_\alpha \rangle \rangle$$

(15)

By using Eq. (13), we can get rid of the sum in Eq. (15), which implies

$$\dot{c}_\beta = c_\beta \langle\langle \mathcal{E}_\beta | \mathcal{O} | D_\beta \rangle \rangle$$

(16)

Solving Eq. (16), we obtain

$$c_\beta(t) = c_\beta(0) e^{\int_0^t \langle\langle \mathcal{E}_\beta| \mathcal{O} | D_\beta \rangle \rangle dt'}$$

(17)

Therefore, each right eigenvector $| D_\beta \rangle \rangle$ in the expansion of $\rho$ gets multiplied by a phase. The first exponential in Eq. (17) gives origin to the geometric contribution of the phase whereas the second exponential generates the dynamical sector. The geometric phase must be gauge invariant, i.e. it cannot be modified (or eliminated) by a multiplication of the basis vectors $\{|D_\alpha\rangle\}$ or $\{\langle\langle \mathcal{E}_\alpha |\rangle\}$ by a local (time-dependent) complex factor. Indeed, let us consider the redefinition $|D_\alpha\rangle = \chi(t) e^{i\nu(t)} |D_\alpha\rangle$ ($\chi(t) \neq 0, \forall t$). For the left vectors, the orthonormality condition, given by Eq. (6), imposes that $\langle\langle \mathcal{E}_\alpha | = \langle\langle \mathcal{E}_\alpha | \chi^* e^{-i\nu(t)}$. Gauge invariance under these transformations for an arbitrary (cyclic or non-cyclic) path in Hilbert-Schmidt space is achieved by adding a new term in the expression of the GP in Eq. (17), resulting in

$$\varphi_\beta = \ln (\langle\langle \mathcal{E}_\beta(0)| D_\beta(t) \rangle \rangle) - \int_0^t \langle\langle \mathcal{E}_\beta(t')| \frac{\partial}{\partial t'} | D_\beta(t') \rangle \rangle dt'$$

(18)

By a direct inspection, it can be shown that $\varphi_\beta$ is gauge invariant. This is analogous to the procedure used in Ref. [4] to extend Berry phases for non-cyclic paths in closed systems. The contribution coming from the term $\ln (\langle\langle \mathcal{E}_\beta(0)| D_\beta(t) \rangle \rangle)$ may affect the visibility of the phase, since $\langle\langle \mathcal{E}_\beta(0)| D_\beta(t) \rangle \rangle$ is not necessarily a complex number with modulus 1. Moreover, note that for a cyclic path of the basis vectors, i.e., $|D_\alpha(t)\rangle = |D_\alpha(0)\rangle$, we have $\ln (\langle\langle \mathcal{E}_\beta(0)| D_\beta(0) \rangle \rangle) = \ln 1 = 0$. Therefore, for the cyclic GP, no extra term should be added, with $\varphi_\beta$ simplifying to

$$\varphi_{\beta, \text{cyclic}} = -\int_0^t \langle\langle \mathcal{E}_\beta(t')| \frac{\partial}{\partial t'} | D_\beta(t') \rangle \rangle dt' \quad \text{(cyclic path)}$$

(19)

Observe also that the phases defined above are non-adiabatic, since no adiabaticity requirement has been imposed in any step of our derivation.

B. Non-Abelian case

Let us consider now the case of 1D degenerate Jordan blocks and expand the density operator as

$$|\rho\rangle = \sum \alpha = 1 \sum m_j c_{\alpha(j)} |D_{\alpha(j)}\rangle \rangle$$

(20)

where $m$ is the number of Jordan blocks and $j$ identifies all the right eigenvectors $| D_{\alpha(j)} \rangle \rangle$ of $\mathcal{I}(t)$ associated with the eigenvalue $\lambda_\alpha$. Similarly as in the non-degenerate case, we insert Eq. (20) into Eq. (2) and project the result in $\langle\langle \mathcal{E}_\beta |$, yielding

$$\dot{c}_{\beta}^{(i)} = \sum \alpha = 1 \sum m_j c_{\alpha(j)} \langle\langle \mathcal{E}_\beta | \mathcal{O} | D_{\alpha(j)} \rangle \rangle$$

(21)

By making use of Eq. (13), we obtain

$$\dot{c}_{\beta}^{(i)} = \sum j = 1 c_{\alpha(j)} \langle\langle \mathcal{E}_\beta | \mathcal{O} | D_{\beta(j)} \rangle \rangle$$

(22)

Now let us define the matrix $M_{\beta}$, whose elements are given by

$$M_{\beta}^{(i)} = \langle\langle \mathcal{E}_\beta | \mathcal{O} | D_{\beta(j)} \rangle \rangle = H_{\beta}^{(i)} + A_{\beta}^{(i)}$$

(23)

with

$$H_{\beta}^{(i)} = \langle\langle \mathcal{E}_\beta | \mathcal{L} | D_{\beta(j)} \rangle \rangle$$

$$A_{\beta}^{(i)} = -\langle\langle \mathcal{E}_\beta | \frac{\partial}{\partial t} | D_{\beta(j)} \rangle \rangle$$

(24)

Note that $H_{\beta}$ plays the role of a non-Abelian dynamical phase while $A_{\beta}$ will correspond to a geometrical contribution with

$$\varphi_{\beta} = M_{\beta} \overline{c}_{\beta}$$

(25)

whose formal solution is

$$\overline{c}_{\beta}(t) = U_{\beta} \overline{c}_{\beta}(0)$$

(26)

with

$$U_{\beta} = T \exp \left[ \int_0^t [H_{\beta}(t') + A_{\beta}(t')] dt' \right]$$

(27)

where $T$ is the time-ordering operator. It is important to note that the matrices $H_{\beta}$ and $A_{\beta}$ do not commute in general. This means that, in the non-Abelian case, the dynamical and GPs may not be easily splitted up. This is indeed a feature which also appears in closed systems for non-adiabatic non-Abelian phases [24, 26, 31]. By assuming that
In this case, by taking into account Eq. (3), we will obtain
which can be verified by a similar inspection as that discussed in Subsection [ IIIA]. Moreover, note that $\mathcal{W}_\beta$ reduces to the
identity for cyclic evolutions.

C. Adiabatic limit

Let us turn now to an observation about the adiabatic regime. The GPs defined in the previous sections will get reduced to the adiabatic case introduced in Ref. [19] for the choice of a slowly varying dynamical invariant. Indeed, let us suppose that

$$\frac{\partial \mathcal{I}}{\partial t} \approx 0.$$  \hspace{1cm} (28)

In this case, by taking into account Eq. (3), we will obtain $[\mathcal{L}, \mathcal{I}] \approx 0$. Then, by assuming that both $\mathcal{L}$ and $\mathcal{I}$ are diagonalizable, it follows that they will have a common basis of eigenstates. Therefore, under the condition (28), the non-adiabatic basis, given by eigenstates of $\mathcal{I}$ will exactly be the same as the adiabatic basis, given by the eigenstates of $\mathcal{L}$.

IV. NON-ADIABATIC GP FOR A TWO-LEVEL SYSTEM UNDER DECOHERENCE

Let us examine the GP acquired by a two-level system described by the free Hamiltonian

$$H = \frac{\omega}{2} \sigma_z.$$  \hspace{1cm} (29)

Under decoherence in a Markovian environment, the dynamics of the system will be governed by the Lindblad equation [14]

$$\frac{\partial \rho}{\partial t} = -i[H, \rho] - \frac{1}{2} \sum_{i} \left( \Gamma_i^\dagger \Gamma_i \rho + \rho \Gamma_i^\dagger \Gamma_i - 2 \Gamma_i \rho \Gamma_i^\dagger \right).$$  \hspace{1cm} (30)

A. Robustness under dephasing

Let us start by taking the case of dephasing, where $\Gamma(t) = \gamma_d \sigma_z$. In this case, the super-operator $\mathcal{L}$ can be written as (see Appendix [A])

$$\mathcal{L} = \begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & -2\gamma_d^2 & -\omega & 0 \\
\omega & -2\gamma_d^2 & 0 & 0 \\
0 & 0 & 0 & 0
\end{pmatrix}.$$  \hspace{1cm} (31)

Therefore, $\mathcal{L}$ has a $2 \times 2$ matrix representation given by

$$\mathcal{L} = \begin{pmatrix}
-2\gamma_d^2 & -\omega \\
\omega & -2\gamma_d^2
\end{pmatrix}.$$  \hspace{1cm} (32)

Let us look for a simple non-trivial super-operator $\mathcal{I}(t)$, which we propose to take the form

$$\mathcal{I} = \begin{pmatrix}
\alpha(t) & \beta(t) \\
\gamma(t) & \delta(t)
\end{pmatrix},$$  \hspace{1cm} (33)

where $\alpha(t)$, $\beta(t)$, $\gamma(t)$, and $\delta(t)$ are time-dependent well-behaved functions. Now, it follows an important fact about the robustness of the non-adiabatic GP. For arbitrary time-dependent functions $\alpha(t)$, $\beta(t)$, $\gamma(t)$, and $\delta(t)$, we have that the commutator $[\mathcal{L}, \mathcal{I}]$ is independent of the dephasing parameter $\gamma_d$. Indeed

$$[\mathcal{L}, \mathcal{I}] = \omega \begin{pmatrix}
-\beta - \gamma & \alpha - \delta \\
\alpha - \delta & \beta + \gamma
\end{pmatrix}.$$  \hspace{1cm} (34)

Due to this property, we can construct a non-trivial (time-dependent) super-operator $\mathcal{I}(t)$ that is independent of $\gamma_d$. This operator will generate right and left bases which are also independent of $\gamma_d$. Hence the GP acquired by the density operator $\rho$ will keep the independence of $\gamma_d$, exhibiting therefore robustness against dephasing.

Let us analyze in details the GP acquired during a cyclic path of the left and right vectors. By imposing Eq. (3), we will get a set of coupled differential equations

$$\dot{\alpha} = -\omega (\beta + \gamma),$$
$$\dot{\beta} = \omega (\alpha - \delta),$$
$$\dot{\gamma} = \omega (\alpha - \delta),$$
$$\dot{\delta} = \omega (\beta + \gamma).$$  \hspace{1cm} (35)

The solution of this set of equations yields

$$\mathcal{I} = \begin{pmatrix}
\alpha(t) & \beta(t) \\
\beta(t) + c_2 & -\alpha(t) + c_1
\end{pmatrix},$$  \hspace{1cm} (36)

where

$$\alpha(t) = \alpha_1 \cos 2\omega t + \alpha_2 \sin 2\omega t + \frac{c_1}{2},$$
$$\beta(t) = \alpha_1 \sin 2\omega t - \alpha_2 \cos 2\omega t - \frac{c_2}{2}.$$  \hspace{1cm} (37)

with $\alpha_1$, $\alpha_2$, $c_1$, and $c_2$ denoting arbitrary constants. Therefore, as mentioned before, we can construct the dynamical invariant such that it is independent of $\gamma_d$. The super-operator $\mathcal{I}(t)$ given in Eq. (36) has a basis of eigenvectors as long as $4(\alpha_1^2 + \alpha_2^2) \neq c_2^2$. This can be adjusted with no problem since we are free to set the constants. The operator $\mathcal{I}(t)$ is in general non-Hermitian, which means that the left and right bases will not be related by a transpose conjugation operation. The cyclic GPs $\varphi_1$ and $\varphi_2$ associated with the right vectors $|D_1\rangle$ and $|D_2\rangle$, respectively, can be computed as given by Eq. (19), yielding

$$\varphi_1 = -\int_0^t \langle E_1 | \frac{\partial}{\partial t} | D_1 \rangle dt',$$  \hspace{1cm} (38)
$$\varphi_2 = -\int_0^t \langle E_2 | \frac{\partial}{\partial t} | D_2 \rangle dt'.$$  \hspace{1cm} (39)
Indeed, by choosing a cyclic path for the basis vectors, we set \( t = 2\pi/\omega \). Therefore, we obtain

\[
\begin{align*}
\varphi_1 &= -2\pi \frac{c_2 v_1 + 2 v_2 \sqrt{-(v_1/v_3)^2}}{v_1 v_3}, \\
\varphi_2 &= -\varphi_1, 
\end{align*}
\]

where \( v_1 \equiv 2\alpha_2 + c_2, v_2 \equiv \alpha_1^2 + \alpha_2^2, \) and \( v_3 \equiv \sqrt{4v_2 - c_2^2} \). Note that the GP depends on the particular choice of the super-operator \( \mathcal{I}(t) \), since it depends on the values of \( \alpha_1, \alpha_2, \) and \( c_2 \). Indeed, different choices of \( \mathcal{I}(t) \) will imply in distinct right and left bases. An interesting particular case is the choice \( c_2 = 0 \). In this situation, we obtain

\[
\begin{align*}
\varphi_1 &= -i\pi \frac{\alpha_2}{\alpha_2} = -i\pi \text{sign}(\alpha_2), \\
\varphi_2 &= +i\pi \frac{\alpha_2}{\alpha_2} = +i\pi \text{sign}(\alpha_2). 
\end{align*}
\]

Note that, besides robustness against dephasing, the GPs given by Eqs. (41) and (42) display only an oscillating (imaginary) term. The loss of visibility typical in open systems, which is given by the presence of damping real exponentials, is absent for the GP in the case \( c_2 = 0 \). Naturally, a loss of visibility may still come (and indeed it does) from the dynamical phase.

### B. Robustness under spontaneous emission

Now let us analyze the robustness of the GP against spontaneous emission, which is modelled by \( \Gamma = \gamma_{se} \sigma_- \), with \( \sigma_- = \sigma_x - i\sigma_y \). In this case, the Lindblad super-operator is given by (see Appendix A)

\[
\begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & -2\gamma_{se} & -\omega & 0 \\
0 & \omega & -2\gamma_{se} & 0 \\
4\gamma_{se}^2 & 0 & 0 & -4\gamma_{se}^2
\end{pmatrix}.
\]

The super-operator \( \mathcal{L} \) motivates the proposal of the dynamical invariant

\[
\mathcal{I}(t) = \begin{pmatrix} q(t) & 0 & 0 & p(t) \\ 0 & \alpha(t) & \beta(t) & 0 \\ 0 & \gamma(t) & \delta(t) & 0 \\ x(t) & 0 & 0 & y(t) \end{pmatrix},
\]

where the matrix elements are arbitrary time-dependent functions. The commutator \( [\mathcal{L}, \mathcal{I}] \) is now given by

\[
\begin{pmatrix}
4\gamma_{se}^2 p & 0 & 0 & 2\gamma_{se}^2 p \\
0 & -\varepsilon & \omega & \eta & \omega & 0 \\
0 & \eta & \varepsilon & \omega & 0 & 0 \\
-4\gamma_{se}^2 (q + x - y) & 0 & 0 & -4\gamma_{se}^2 p
\end{pmatrix},
\]

where \( \varepsilon = \beta + \gamma \) and \( \eta = \alpha - \delta \). We observe that the commutator is splitted out in two submatrices. The internal submatrix is identical to that obtained from dephasing [see Eq. (44)], being independent of the decoherence parameter \( \gamma_{se} \). In order to ensure robustness for the external submatrix, we must impose \( p = 0 \) (implying from Eq. (5) that both \( q \) and \( y \) are constants) and \( q = y - x \) (implying that \( z \) is also a constant). Since, as given by Eq. (44), the internal and the external submatrix are decoupled, only the internal submatrix will contribute for the GP (the constant elements of the external submatrix will disappear in the computation of the GP, due to the time derivative). This means that: (i) the invariant super-operator \( \mathcal{I}(t) \) for spontaneous emission given by Eq. (44) will produce the same GP as that obtained for dephasing; (ii) since \( \mathcal{I}(t) \) can be non-trivially defined as independent of \( \gamma_{se} \), then the non-adiabatic GP acquired by \( \rho \) in the basis of \( \mathcal{I}(t) \) is robust against spontaneous emission. The robustness of the geometric phase under spontaneous emission appears here as a consequence of the expansion of the density operator \( \rho \) in the basis of a suitably chosen invariant super-operator (see, e.g., Ref. [16] for an analysis based on quantum trajectories of a geometric phase which is non-robust against spontaneous emission).

### C. An example of non-robustness: bit-flip

Robustness will not be present for arbitrary processes. For instance, consider the case of bit-flip, i.e. \( \Gamma = \gamma_b \sigma_x \). In this case, the Lindblad super-operator reads (see Appendix A)

\[
\mathcal{L} = \begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & \omega & -2\gamma_b^2 & \eta \\
0 & -2\gamma_b^2 & \eta & \omega \\
-2\gamma_b^2 x & 0 & 0 & 0
\end{pmatrix},
\]

Consider that we propose the dynamical invariant \( \mathcal{I}(t) \) given by Eq. (44). The commutator \( [\mathcal{L}, \mathcal{I}] \) now yields

\[
[\mathcal{L}, \mathcal{I}] = \begin{pmatrix}
0 & 0 & 0 & 2\gamma_b^2 p \\
0 & -\varepsilon & \omega & 2\beta \gamma_b^2 + \eta \omega \eta & 0 \\
0 & -2\gamma_b^2 & \eta & \varepsilon & \omega & 0 \\
-2\gamma_b^2 x & 0 & 0 & 0
\end{pmatrix},
\]

where, as defined for the case of spontaneous emission, \( \varepsilon = \beta + \gamma \) and \( \eta = \alpha - \delta \). Therefore, the requirement of independence of \( \gamma_b \) yields \( x = 0, p = 0, \omega(\alpha - \delta) = -2\beta \gamma_b^2 \), and \( \omega(\alpha - \delta) = -2\gamma_b^2 \). Then, by using Eqs. (37), we obtain \( \alpha = c_1/2 \) and \( \beta = -c_2/4 \) which, from Eq. (36), imply that \( \alpha, \beta, \gamma, \) and \( \delta \) are constants. Moreover, requiring Eq. (5) for the dynamical invariant, we also find that \( q \) and \( y \) are constants. Therefore \( \mathcal{I} \) as given by Eq. (44) cannot result in non-vanishing GPs which are robust against bit-flip, since the robust dynamical invariant obtained is trivially constant. Thus, let us turn to the case of time-dependent \( \mathcal{I}(t) \) and explicitly analyze the dependence of the geometric phase on the parameter \( \gamma_b \). By taking \( x = 0 \) and \( p = 0 \) in Eq. (47), we can choose the dynamical invariant as

\[
\mathcal{I} = \begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & \alpha(t) & \beta(t) & 0 \\
0 & \gamma(t) & \delta(t) & 0 \\
0 & 0 & 0 & 0
\end{pmatrix},
\]
where now the functions \( \alpha(t), \beta(t), \gamma(t), \) and \( \delta(t) \) satisfy the following set of differential equations

\[
\begin{align*}
\dot{\alpha} &= - (\beta + \gamma) \omega \\
\dot{\beta} &= 2 \beta \gamma_t^2 + (\alpha - \delta) \omega \\
\dot{\gamma} &= -2 \gamma \gamma_t^2 + (\alpha - \delta) \omega \\
\dot{\delta} &= (\beta + \gamma) \omega
\end{align*}
\] (49-52)

The solution of Eqs. (49)-(52) can be written as

\[
\begin{align*}
\alpha(t) &= \omega \left( - \varepsilon_1 e^{2 \xi t} + \varepsilon_2 e^{-2 \xi t} \right) + \alpha_1, \\
\beta(t) &= \frac{\varepsilon(t) + \sigma(t)}{2}, \\
\gamma(t) &= \frac{\varepsilon(t) - \sigma(t)}{2}, \\
\delta(t) &= -\alpha(t) + c_1 \tag{53}
\end{align*}
\]

with \( \alpha_1, \varepsilon_1, \varepsilon_2, \) and \( c_1 \) are constants, \( \xi = (\gamma_b^2 - \omega^2)^{1/2} \)

\[
\varepsilon(t) = \varepsilon_1 e^{2 \xi t} + \varepsilon_2 e^{-2 \xi t}, \tag{54}
\]

\[
\sigma(t) = \gamma_b^2 \left( \varepsilon_1 e^{2 \xi t} - \varepsilon_2 e^{-2 \xi t} \right) + \sigma_1,
\]

where \( \varepsilon_1, \gamma_b, \) and \( \sigma_1 \) are constants, \( \xi = (\gamma_b^2 - \omega^2)^{1/2} \)

This GP is non-cyclic and evaluated for the eigenstate of \( I \) associated with the eigenvalue \( \alpha_1 - \sqrt{\varepsilon_1 \varepsilon_2} \) (the GP is independent of \( \alpha_1 \)). Note that the visibility of \( \phi \) decreases faster as we increase the evolution time \( t \). Concerning the imaginary part of \( \phi \), it can be shown that it is independent of \( \gamma_b \) for a given time \( t \).

We can also consider the dependence of the GP as time is varied for a fixed \( \gamma_b \). This is plotted in Fig. 2 and Fig. 3, where we fix \( \gamma_b = 0.1 \) (in units such that \( \omega = 1 \)). As we can observe in Fig. 2, the imaginary part of the gauge-invariant GP, which is the sum of \( \phi^{\text{cyclic}} \) (See Eq. 13) and the logarithmic correction, behaves as a step function of time. The origin of this behavior is the \( \ln \) term in Eq. (13). Moreover, note that the discontinuities in the imaginary part of the GP are associated with a pronounced behavior also in the real part, as exhibited in Fig. 3.

![Fig. 2: (Color online) Imaginary part of the GP for a two-level system under bit-flip as a function of time. The decoherence parameter \( \gamma_b \) is set to 0.1 (in units such that \( \omega = 1 \)).](image)

![Fig. 3: (Color online) Real part of the GP for a two-level system under bit-flip as a function of time. The decoherence parameter \( \gamma_b \) is set to 0.1 (in units such that \( \omega = 1 \)).](image)
due to the fact that the super-operator $\mathcal{L}$ depends on the decoherence parameters. This is in contrast with the invariant super-operator $\mathcal{I}$, which can be designed to display robustness if $[\mathcal{L}, \mathcal{I}]$ is independent of the decohering parameters (as previously shown for dephasing and spontaneous emission). Indeed, robustness of the dynamical phase can only be achieved whether the integral $\int \langle \mathcal{E}_1 | \mathcal{L} | \mathcal{D}_2 \rangle \, dt'$ can be made independent of decoherence, which turns out to be a non-generic situation. As a concrete example, let us consider the dynamical phase for dephasing. In this case, robustness is not possible by choosing the invariant operator given in Subsection [IV A]. In fact, by explicit computation for a cyclic evolution, we obtain

$$\int_0^{2\pi/\omega} \langle \mathcal{E}_1 | \mathcal{L} | \mathcal{D}_2 \rangle \, dt' = -\frac{4\pi}{\omega} \gamma_d^2 + \frac{2e_2\pi}{\nu_3}$$

with $\nu_3$ defined as in Eq. (40). Therefore, notice that no adjustment can be done in order to remove the dependence of the dynamical phase for an arbitrary $\gamma_d$. As expected, this dependence will induce a damping contribution to the visibility of the total phase.

V. CONCLUSIONS

We have proposed a generalization of the theory of dynamical invariants to the context of open quantum systems. This approach can be seen as an alternative way to solve the master equation, since the construction and diagonalization of a dynamical invariant automatically determines the density operator. By using this generalization, we have defined in general non-adiabatic GPs acquired by the density operator during its evolution in Hilbert-Schmidt space. Moreover, we have delineated a strategy to look for non-adiabatic GPs that are robust against a given decoherence process. Our method consists in looking for dynamical invariants such that $[\mathcal{L}, \mathcal{I}]$ is independent of the decohering parameters. As an illustration of our approach, we have analyzed the GP acquired by a qubit evolving under decoherence. GP in this case was shown to be robust against both dephasing and spontaneous emission. Robustness of the non-adiabatic GP against spontaneous emission is a remarkable feature which may have a positive impact in geometric quantum computation. In this direction, a certain interesting application of our approach is the analysis of non-Abelian geometric phases in the tripod-linkage system of atomic states $^{32, 33, 34, 35}$. We left this topic for further research.

APPENDIX A: LINDBLAD SUPER-OPERATOR FOR A TWO-LEVEL SYSTEM UNDER DECOHERENCE

Let us illustrate the construction of the Lindblad super-operator $\mathcal{L}$ by examining a two-level system described by the free Hamiltonian given by Eq. (29). We will consider the following decohering process

$$\Gamma(t) = \alpha_1(t) \sigma_x + \alpha_2(t) \sigma_y + \alpha_3(t) \sigma_z = \sum_{i=1}^{3} \alpha_i(t) \sigma_i, \quad (A1)$$

where $\sigma_1 \equiv \sigma_x$, $\sigma_2 \equiv \sigma_y$, and $\sigma_3 \equiv \sigma_z$. Note that $\Gamma(t)$ describes an arbitrary single decoherence process for a two-level system. For instance, for dephasing, we would take $\alpha_1 = \alpha_2 = 0$. For the density operator, we can take the expression

$$\rho(t) = \frac{1}{2} (I + \bar{v} \cdot \sigma) = \frac{1}{2} (I + v_1 \sigma_x + v_2 \sigma_y + v_3 \sigma_z), \quad (A2)$$

where $I$ is the two-dimensional identity operator and $\bar{v}$ is the coherence vector. By inserting Eqs. (29), (A1), and (A2) into the Lindblad equation (30) we obtain

$$\frac{\partial \rho}{\partial t} = \frac{\omega}{2} (v_1 \sigma_2 - v_2 \sigma_1) + \sum_{i,j} \frac{\alpha_i^\dagger \alpha_j}{2} (v_i \sigma_j + v_j \sigma_i) - \sum_{i,j} |\alpha_i|^2 v_j \sigma_j - \sum_{i,j,k} i \varepsilon_{ijk} \alpha_i^\dagger \alpha_j \sigma_k \quad (A3)$$

where we have made use of the auxiliary expressions

$$\sigma_i \sigma_j = i \varepsilon_{ijk} \sigma_k + \delta_{ij} I, \quad \varepsilon_{ijk} \varepsilon_{pqk} = \delta_{ip} \delta_{jq} - \delta_{iq} \delta_{jp}, \quad (A4)$$

with the repeated indices $k$ summed over and with $\varepsilon_{ijk}$ denoting the Levi-Civita symbol (it is 1 if $(i, j, k)$ is an even permutation of $(1, 2, 3)$, and 1 if it is an odd permutation, and 0 if any index is repeated). Factoring out the components in each $\sigma_i$-direction, Eq. (A3) can be rewritten as...
\[
\frac{\partial \rho}{\partial t} = \left[ -\frac{\omega v_2}{2} + \left( a_1 a_3 + a_1 a_3^\dagger \right) v_2 + \left( a_1 a_3 + a_1 a_3^\dagger \right) v_3 - \left( |a_2|^2 + |a_3|^2 \right) v_1 \right. \\
+ \left( \frac{\omega v_1}{2} + \left( a_1 a_2 + a_1 a_2^\dagger \right) v_1 + \left( a_1 a_2 + a_1 a_2^\dagger \right) v_3 - \left( |a_1|^2 + |a_3|^2 \right) v_2 \right. \\
+ \left. \left( a_1 a_3 + a_1 a_3^\dagger \right) v_1 + \left( a_3 a_3 + a_2 a_3^\dagger \right) v_2 - \left( |a_1|^2 + |a_2|^2 \right) v_3 \right] \sigma_1 \\
+ \left( a_1 a_2 - a_1 a_2^\dagger \right) v_1 + \left( a_3 a_3 + a_2 a_3^\dagger \right) v_2 - \left( |a_1|^2 + |a_2|^2 \right) v_3 + \left( a_1 a_2 - a_1 a_2^\dagger \right) \sigma_3 \tag{A5} \]

Taking \( \rho(t) \) as a vector in Hilbert-Schmidt space and using Eq. (A2), we can write

\[
|\rho(t)\rangle = \frac{1}{2} \begin{pmatrix} v_1 \\ v_2 \\ v_3 \end{pmatrix} \tag{A6}
\]

Therefore, by inserting Eq. (A6) and Eq. (A5) (for \( \frac{\partial}{\partial t} \)) into Eq. (2), we obtain the Lindblad super-operator \( \mathcal{L} \)

\[
\mathcal{L} = \begin{pmatrix} 0 & 0 & 0 \\ -2 |a_2|^2 - |a_3|^2 & 0 & \omega + |a_1|^2 + |a_2|^2 \\ 2 i \left( a_1 a_3 - a_3 a_1^\dagger \right) & \omega + i a_1 a_2 + a_1 a_2^\dagger & 0 \end{pmatrix} \tag{A7}
\]

Some interesting particular cases of Eq. (A7) can be obtained. For instance, for dephasing, we have \( a_1 = a_2 = 0 \) and \( a_3 \equiv \gamma_d \), resulting in Eq. (A1). Note that the first column of \( \mathcal{L} \) vanishes for dephasing. In fact, this will be the case whenever the parameters \( \alpha_i \) are real. An interesting case of complex \( \alpha_i \) is given by spontaneous emission, where \( \alpha_1 \equiv \gamma, \alpha_2 \equiv -i \gamma, \) and \( \alpha_3 = 0 \). In this case, we obtain the super-operator \( \mathcal{L} \) shown in Eq. (A3).
