A SIMPLIFIED PROOF OF THE RELATION BETWEEN SCALING EXPONENTS IN FIRST-PASSAGE PERCOLATION

BY ANTONIO AUFFINGER AND MICHAEL DAMRON

University of Chicago and Princeton University

In a recent breakthrough work, Chatterjee [Ann. of Math. (2) 177 (2013) 663–697] proved a long standing conjecture that relates the transversal exponent $\xi$ and the fluctuation exponent $\chi$ in first-passage percolation on $\mathbb{Z}^d$. The purpose of this paper is to replace the main argument of Chatterjee (2013) and give an alternative proof of this relation. Specifically, we show that under the assumption that exponents defined in Chatterjee (2013) exist, one has the relation $\chi \leq 2\xi - 1$. One advantage of our argument is that it does not require the “nearly Gamma” assumption of Chatterjee (2013).

1. Introduction. We consider first-passage percolation (FPP) on $\mathbb{Z}^d$ with nonnegative i.i.d. weights $(\tau_e)$ on edges with common distribution $\mu$. For a review and a description of known results on the model we refer the reader to [4, 8, 12].

The random variable $\tau_e$ is called the passage time of the edge $e$, a nearest-neighbor edge in $\mathbb{Z}^d$. A path $\gamma$ is a sequence of edges $e_1, e_2, \ldots$ in $\mathbb{Z}^d$ such that for each $n \geq 1$, $e_n$ and $e_{n+1}$ share exactly one endpoint. For any finite path $\gamma$ we define the passage time of $\gamma$ to be $\tau(\gamma) = \sum_{e \in \gamma} \tau_e$, and given two points $x, y \in \mathbb{R}^d$ we set

$$\tau(x, y) = \inf_{\gamma} \tau(\gamma).$$

The infimum is over all paths $\gamma$ that contain both $x'$ and $y'$, and $x'$ is the unique vertex in $\mathbb{Z}^d$ such that $x \in x' + [0, 1)^d$ (similarly for $y'$). A minimizing path for $\tau(x, y)$ is called a geodesic from $x$ to $y$. We assume throughout the paper that $\mu$ has no mass larger than or equal to $p_c(d)$, the critical probability of bond percolation, at the infimum of its support.

Consider a geodesic from the origin to a point $v$ with passage time $\tau(0, v)$. One of the central questions [8, 12] in this model (and in related ones) is to prove the following statement. There exists an intrinsic relation between the magnitude of deviation of $\tau(0, v)$ from its mean and the magnitude of deviation of the geodesic $\tau(0, v)$ from a straight line joining 0 and $v$. This relation is universal; that is, it is independent of the dimension $d$ and of the law of the weights (as long they satisfy certain moment assumptions).
The fluctuations of the passage time $\tau(0,v)$ about $\mathbb{E}\tau(0,v)$ should be of order $|v|^\chi$, where $\chi$ is called the fluctuation exponent. Analogously, a transversal exponent $\xi$ should measure the maximal Euclidean distance of a geodesic from 0 to $v$ from the straight line that joins 0 to $v$. The intrinsic relation described above should be given as

$$\chi = 2\xi - 1.$$  

Despite numerous citations (both in mathematics and physics papers [10, 13–15, 17]) and the mystery surrounding (1.1), the existence and the “correct” definition of these exponents is still not established, and these issues form part of the above conjecture.

For a certain definition of the exponents, the inequality $\chi \geq 2\xi - 1$ was proved and understood in the 1995 work of Newman and Piza [15]. The other inequality, however, has remained elusive for more than twenty years. A recent work of Chatterjee [5] proposed a stronger definition of the exponents that allows a complete proof of (1.1). One of its main contributions was to give proof of the inequality $\chi \leq 2\xi - 1$. The proof relies on a construction similar to that in [6]. One first breaks a geodesic into smaller segments and then uses an approximation scheme to compare the passage time to a sum of nearly i.i.d. random variables. The proof is then a trade-off between minimizing the error while maximizing the variance of the passage time. Assuming that the distribution is “nearly Gamma” (see [3] for a definition), the optimization can be achieved by choosing different parameters in the approximation.

The main goal of this paper is to show a simple idea that enables us to replace the main argument of [5] to prove the inequality $\chi \leq 2\xi - 1$ in the case $\chi > 0$. Our proof does not use a “nearly Gamma” assumption on the passage times, and so it applies to all distributions for which Chatterjee’s exponents exist. Furthermore, this idea allows us to extend our theorem to related models like directed polymers in random environments and last passage percolation. These questions will be addressed in a forthcoming paper [2]. A secondary goal of this paper is to explain how the simplicity of our proof could allow one to extract weaker assumptions on the model to guarantee that different versions of (1.1) hold. It is important to note that the cylinder construction we use has appeared in both [9] and [17] to prove two-dimensional versions of the scaling relation for related models in either exactly solvable or Poissonized cases.

We close this section by discussing earlier works related to (1.1) and sketching the idea of Newman and Piza [15]. In 1993, Kesten [11] showed that $\chi \leq \frac{1}{2}$. In 1996, Licea, Newman and Piza [14] proved that $\xi \geq \frac{1}{2}$ in all dimensions for one definition of $\xi$ and $\xi \geq \frac{3}{5}$ in two dimensions for another definition. In Section 4.2, we use their cylinder construction [14] as a fundamental tool to obtain the proof of (1.1). The most well-known conjecture after (1.1) is, however, that in two dimensions one should have the exact values $\xi = \frac{2}{3}$ and $\chi = \frac{1}{3}$.
The proof of Newman and Piza [15] was based on an argument of Aizemann and Wehr [16] (in a different context) with important contributions from Alexander [1] and Kesten [11]. Their main tool was an assumption of curvature of the limit shape $B_\mu$ [defined in (3.1)] and the following argument; see Figure 1. Let $v$ be a unit vector. Assume that a geodesic from 0 to $nv$ leaves a box of height $n^\xi$ centered on the straight line that joins the origin to $nv$ through a point $w$. Furthermore, assume that the limit shape has shape curvature 2 in the direction of $v$; that is, there exists a positive constant $c$ such that

\begin{equation}
|z|^2 \leq |g(v + z) - g(v)| \leq c|z|^2
\end{equation}

for all vectors $z$ orthogonal to $v$ of small length. (A precise definition of the shape curvature will be given in Section 3.) The passage time being additive in a geodesic implies that

\begin{equation}
\tau(0, nv) = \tau(0, w) + \tau(w, nv).
\end{equation}

Alexander’s subadditive approximation theorem [1] [see (4.1)] guarantees that $\tau(0, w) + \tau(w, nv) - \mathbb{E}\tau(0, nv)$ is within $O(n^\chi)$ of $g(w) + g(nv - w) - g(nv)$, which is equal to $g(\lambda v - (\lambda v - w)) + g((n - \lambda)v - (w - \lambda v)) - g(nv)$; see Figure 1. By the curvature assumption (1.2) and by linearity of $g$ in the direction of $v$ this term is of order at least $\frac{|w - \lambda v|^2}{n} = n^{2\xi - 1}$ regardless of the choice of $w$. This contradicts the fact that $\tau(0, nv) - \mathbb{E}\tau(0, nv)$ has order $n^\chi$ if $\chi < 2\xi - 1$, proving the lower bound.

1.1. Outline of the paper. In the next section, we state our main result and give a sketch of the proof. Next, in Section 3, we discuss how our proof could give rise to important extensions. In Section 4 we prove Theorem 2.1.

2. Results. Let $D(0, v)$ be the maximum Euclidean distance between the set of all geodesics from 0 to $v$ and the line segment joining 0 to $v$. We say that the FPP model has \textit{global exponents in the sense of Chatterjee} if there exist real numbers $\chi_a$, $\chi_b$ and $\xi_a$, $\xi_b$ such that:
(1) For each choice of $\chi' > \chi_a$ and $\xi' > \xi_a$, there exists $\alpha > 0$ so that
\[
\sup_{v \in \mathbb{Z}^d \setminus \{0\}} \mathbb{E} \exp \left( \alpha \frac{|\tau(0, v) - \mathbb{E} \tau(0, v)|}{|v|^{\chi'}} \right) < \infty \quad \text{and}
\]
\[
\sup_{v \in \mathbb{Z}^d \setminus \{0\}} \mathbb{E} \exp \left( \alpha \frac{D(0, v)}{|v|^{\xi'}} \right) < \infty.
\]

(2) For each choice of $\chi'' < \chi_b$ and all $\xi'' < \xi_b$,
\[
\inf_{v \in \mathbb{Z}^d \setminus \{0\}} \frac{\text{Var}(\tau(0, v))}{|v|^{2\chi''}} > 0 \quad \text{and} \quad \inf_{v \in \mathbb{Z}^d \setminus \{0\}} \frac{\mathbb{E}(D(0, v))}{|v|^{\xi''}} > 0.
\]

REMARK 1. It is not difficult to prove (see [5]) that if such exponents exist, then $0 \leq \xi_b \leq \xi_a \leq 1$ and $0 \leq \chi_b \leq \chi_a \leq \frac{1}{2}$.

Our main result is the following.

**THEOREM 2.1.** Assume that the FPP model has global exponents in the sense of Chatterjee and $\chi := \chi_a = \chi_b > 0$. Then
\[
\chi \leq 2\xi_a - 1.
\]

**REMARK 2.** Our proof does not require one to assume that the distribution $\mu$ of the $\tau_i's$ is nearly Gamma as in [5]. The case $\chi = 0$ was treated with a separate argument in [5]. It does not require this assumption on $\mu$, and although it is stated for continuous distributions only, the arguments hold under our condition on the support of $\mu$.

In [5] it was shown using the ideas of Newman and Piza [15] and Howard [8] that for this definition of exponents, the lower bound holds,
\[
\chi_a \geq 2\xi_b - 1.
\]
This fact, combined with Theorem 2.1 and with the assumption $\xi_a = \xi_b$, implies:

**THEOREM 2.2.** Assume that the FPP model has global exponents in the sense of Chatterjee with $\chi := \chi_a = \chi_b$ and $\xi := \xi_a = \xi_b$. Then (1.1) holds.

2.1. Sketch of the proof. In this subsection we sketch the proof of Theorem 2.1. It will follow from the picture below.

Look at the cylinders $C_1$ and $C_2$ in Figure 2. They are both of length $n$ and radius $n^{\xi'}$ for some $\xi' > \xi_a$. The top cylinder is identical to the bottom but shifted up (in direction $e_2$, the second coordinate vector) by $4n^{\xi'}$. The dark paths $\gamma_1$ and $\gamma_2$ joining 0 to $ne_1$ and their shifted points are geodesics.
Since we chose $\xi' > \xi_a$ it is possible to show that the passage times $\tau(\gamma_1)$ and $\tau(\gamma)$ are almost independent. Using (2.2), this implies that for any $\chi'' < \chi$ and $n$ large,

\begin{equation}
 n^{2\chi''} \leq \text{Var}(\tau(\gamma_2) - \tau(\gamma_1)).
\end{equation}

Assuming $\xi_a < 1$ and $\xi' < \beta < 1$, build two cylinders, $B_1$ and $B_2$, of length $n^\beta$ and radius $3n^{\xi'}$ as in the picture. Let $a_1$ and $a_2$ be the last and first points of intersection of the geodesic $\gamma_2$ with these cylinders. Consider the geodesics $\pi_1$ joining 0 to $a_1$ and $\pi_2$ joining $a_2$ to $ne_1$ (in blue). Note that the concatenation of $\pi_1$, the piece of $\gamma_2$ from $a_1$ to $a_2$ and $\pi_2$ is a path from 0 to $ne_1$. Therefore, if $s_1$ and $s_2$ are the other two parts of $\gamma_2$ (as in the picture),

$$
\tau(\gamma_1) \leq \tau(\pi_1) + \tau(a_1, a_2) + \tau(\pi_2) = \tau(\pi_1) + (\tau(\gamma_2) - \tau(s_1) - \tau(s_2)) + \tau(\pi_2),
$$

which implies

\begin{equation}
\tau(\gamma_1) - \tau(\gamma_2) \leq \tau(\pi_1) - \tau(s_1) + \tau(\pi_2) - \tau(s_2).
\end{equation}

The difference $\tau(\pi_1) - \tau(s_1)$ is bounded above by

$$
X := \max_{u,v,u',v' \in \partial B_1} \tau(u, v) - \tau(u', v'),
$$

where $\partial B_1$ is the boundary of $B_1$. This completes the proof of the scaling relation.
where \( u \) and \( u' \) are points on the left boundary of the box \( B_1 \) while \( v \) and \( v' \) are points on the right boundary of the box. Using the box \( B_2 \) one can similarly bound the difference of \( \tau(\pi_2) - \tau(s_2) \) by a random variable with same distribution as \( X \). Using the red paths instead of the blue ones and reversing the roles of \( \gamma_1 \) and \( \gamma_2 \) in (2.6), we get an inequality for the absolute value of the left-hand side of (2.6). Combining these bounds,

\[
\operatorname{Var}(\tau(\gamma_2) - \tau(\gamma_1)) \leq 4EX^2.
\]

For \( EX^2 \) it suffices to bound (independently of \( u \) and \( v \)) the second moment of

\[
\begin{align*}
&|\tau(u, v) - \tau(0, n^\beta e_1)| \\
\leq &\left|\tau(u, v) - \mathbb{E}\tau(u, v)\right| + \left|\tau(0, n^\beta e_1) - \mathbb{E}\tau(0, n^\beta e_1)\right| \\
&+ |g(v-u) - \mathbb{E}g(u,v)| + |g(ne_1) - \mathbb{E}g(0, n^\beta e_1)| \\
&+ |g(v-u) - g(n^\beta e_1)|.
\end{align*}
\]

The first two lines above are bounded above by \( n^\beta \chi' \) for any \( \chi' > \chi \) (by assumption and Alexander’s subadditive approximation) while the third is of order \( n^{2\xi'-\beta} \) by the curvature of the limit shape \( B_\mu \); see (3.1). This implies by (2.5) and the above computation,

\[
(2.8) \quad n^{2\chi''} \leq \operatorname{Var}(\tau(\gamma_2) - \tau(\gamma_1)) \leq C(n^{2\beta \chi'} + n^{2(2\xi'-\beta)}).
\]

Now choosing \( \chi'' \) and \( \chi' \) close enough to \( \chi \) and recalling that \( \beta < 1 \), we get \( n^{2\chi''} \leq Cn^{(2\xi'-\beta)} \) for large \( n \). This implies \( \chi'' \leq 2\xi' - \beta \). Taking \( \beta \uparrow 1 \), \( \chi'' \uparrow \chi \) and \( \xi' \downarrow \xi \) ends the proof.

3. Extensions.  In this section we discuss how to improve Theorem 2.1. There are two main directions. The first one is to establish a relation for directionally defined exponents. This would weaken our assumptions, allowing us to prove the existence of both exponents more easily. The second is to add shape curvature into relation (1.1).

One can define the exponents \( \xi^u_\alpha, \chi^u_\alpha, \chi^u_b \) directionally as follows. For a unit vector \( u \), define the cylinder \( C(u, a, b) \) of length \( a \) and radius \( b \) in the direction \( u \) as the set of points in \( \mathbb{R}^d \) at most \( \ell_\infty \) distance \( b \) away from the line segment connecting 0 to \( au \). We denote \( \partial fC(u, a, b) \) as the set of all points \( x \in C(u, a, b) \) with \( |\langle u, x \rangle| \geq a \).

The exponent \( \xi^u_\alpha \) is now defined as in (2.1) with \( v \) taken as a nonzero multiple of \( u \) instead of an arbitrary vector in \( \mathbb{Z}^d \setminus \{0\} \). \( \chi^u_\alpha \) is defined similarly to (2.1) but as a function of \( \xi^u_\alpha \); it is the smallest real number such that for any \( \chi' > \chi^u_\alpha \), there exists \( \alpha \) so that

\[
\sup_{\xi' > \xi^u_\alpha} \sup_{n \in \mathbb{N}} \sup_{v \in \partial fC(u, a, n\xi')} \mathbb{E}\exp\left(\frac{\alpha |\tau(0, v) - \mathbb{E}\tau(0, v)|}{|v|\chi'}\right) < \infty.
\]
\( \chi^u_b \) is defined as the largest real number such that for any \( \chi'' < \chi^u_b \),

\[
\inf_{n \in \mathbb{N}} \frac{\text{Var} \tau(0, nu)}{n^{2 \chi''}} > 0.
\]

One can go through the proof of Theorem 2.1 and see that the scaling relation (1.1) holds with these new exponents as long one is able to prove that Alexander’s subadditive exponent can be made directional. Namely, the question becomes the following:

**Question 3.1.** Is it true that for any \( \chi' > \chi^u_a \) there exists \( \xi' > \xi^u_a \) and a constant \( C = C(\chi', \xi') > 0 \) such that for all \( x \in \partial f(\tau, n, n \xi') \) and all \( n \),

\[
|\mathbb{E} \tau(0, x) - g(x)| \leq C |x|^{\chi'}.
\]

Another way to generalize the relation (1.1) is to add curvature. Let

\[
B_u := \{ x \in \mathbb{R}^d, g(x) \leq 1 \}
\]

be the limit shape of the model; see [12]. Let \( u \) be a unit vector of \( \mathbb{R}^d \) and let \( H_0 \) be a hyperplane such that \( u + H_0 \) is tangent to \( g(u)B_u \) at \( u \). We introduce a third exponent, called the curvature exponent as follows.

**Definition 3.1.** The curvature exponent \( \kappa^u \) in the direction \( u \) is a real number such that there exist positive constants \( c, C \) and \( \varepsilon \) such that for any \( z \in H_0 \) with \( |z| < \varepsilon \), one has

\[
c|z|^\kappa^u \leq g(u + z) - g(u) \leq C|z|^\kappa^u.
\]

The directional approach mentioned above together with the definition of the curvature exponent allows us to generalize relation (1.1) to one that includes all three of these exponents. Assume that Question 3.1 is answered affirmatively and that \( \chi^u := \chi^u_a = \chi^u_b \). Then it would follow directly from the proof of Theorem 2.1 that (2.3) generalizes to

\[
(3.3) \quad \chi^u \leq \kappa^u \xi^u_a - (\kappa^u - 1).
\]

Moreover, if \( \xi^u := \xi^u_a = \xi^u_b \), then one would have

\[
(3.4) \quad \chi^u = \kappa^u \xi^u - (\kappa^u - 1).
\]

**Remark 3.** Note that when \( \kappa^u = 2 \) and the exponents are global, (3.4) is the same as (1.1). This is believed to be true in the case where the weights \( \tau \) have a continuous distribution with finite exponential moments. It would be of interest to find examples, maybe of other growth models, where (3.3) holds for \( \kappa^u \neq 2 \).
Remark 4. It is unclear if Chatterjee’s exponents exist and, if so, what the implications would be. For example, existence immediately implies that $\kappa_u \leq 2$ in all directions where $\kappa_u$ is defined. In particular the limit shape can not contain flat pieces as in [7]. However, if the statement in Question 3.1 holds and if one uses directional exponents (provided they exist), then it would be possible to show that the upper bound in (3.2) holds for all $\kappa$ (this is true, for example, if there is a flat edge in direction $u$) if and only if $\xi_u = 1$.

4. Proof of Theorem 2.1.

4.1. Preliminary lemmas. Recall the definition of the function $g$ from (1.2). We first state a bound on the “nonrandom fluctuations” from [1]. The proof of the lemma, as stated, can be found in [5].

Lemma 4.1. For any $\chi' > \chi_a$, there exists $C_1 = C_1(\chi') > 0$ such that for all $x \in \mathbb{R}^d$,
$$\left| \mathbb{E} \tau(0,x) - g(x) \right| \leq C_1 |x|^\chi'. $$

For a unit vector $x_0$, let $H_0$ be as in Definition 3.1 (taking $u = x_0$). For $m, n \geq 1$ and $i = 1, 2$, set
$$S_i(x_0; m, n) = \{ x \in (i-1)nx_0 + H_0 : |x - (i-1)nx_0| \leq m \}$$
and
$$X(x_0; m, n) = \max_{v_1, v_2 \in S_1(x_0; m, n)} \max_{w_1, w_2 \in S_2(x_0; m, n)} |\tau(v_1, w_1) - \tau(v_2, w_2)|.$$

The following proposition is a slight modification of the arguments in [5]. For a random variable $G$, write $\|G\|_2$ for the $L^2$ norm $(\mathbb{E}G^2)^{1/2}$.

Proposition 4.2. Let $|x_0| = 1$, and assume (3.2) holds for some $C_{x_0}$, $\kappa$ and $\varepsilon_{x_0}$. For each $\chi' > \chi_a$ there exists $C_2 = C_2(d, \chi')$ such that if $m, n$ have $m \leq (\varepsilon_{x_0}/2\sqrt{d-1})n$, then
$$\|X(x_0; m, n)\|_2 \leq C_2 n^{1-\kappa} m^{\kappa} + C_2 n^{\chi'}.$$

Proof. By the triangle inequality, it suffices to bound the variable $Y$,
$$Y(x_0; m, n) = \max_{v \in S_1(x_0; m, n)} \max_{w \in S_2(x_0, m, n)} |\tau(v, w) - \tau(0, nx_0)|.$$
For \( v \in S_1(x_0; m, n) \) and \( w \in S_2(x_0; m, n) \), the idea is to use the following decomposition:

\[
\left| \tau(0, nx_0) - \tau(v, w) \right| \leq \left| \tau(0, nx_0) - \mathbb{E}\tau(0, nx_0) \right| + \left| \tau(v, w) - \mathbb{E}\tau(v, w) \right| 
\]

(4.1)

\[
+ \left| \mathbb{E}\tau(0, nx_0) - g(nx_0) \right| + \left| \mathbb{E}\tau(v, w) - g(w-v) \right| 
\]

(4.2)

\[
+ \left| g(nx_0) - g(w-v) \right|. 
\]

(4.3)

We first estimate (4.3),

\[
\left| g(nx_0) - g(w-v) \right| = n\left| g(x_0) - g(x_0 + (w-v)/n - x_0) \right|. 
\]

By assumption, \( |(w-v)/n - x_0| = (1/n)|w-v-nx_0| \leq 2(m/n)\sqrt{d-1} \leq \varepsilon_{\chi_0}. \)

Therefore, we can apply (3.2) and find \( C_3 \) such that

\[
\left| g(nx_0) - g(w-v) \right| \leq C_{\chi_0}n\left| (w-v)/n - x_0 \right|^\kappa \leq C_3 n^{1-\kappa} m^\kappa. 
\]

(4.4)

For (4.2), we note that \( |w-v| \leq 2n \) for all \( w, v \). So by Lemma 4.1,

\[
\left| \mathbb{E}\tau(0, nx_0) - g(nx_0) \right| + \left| \mathbb{E}\tau(v, w) - g(w-v) \right| \leq 3C_1 n^{\chi'}.
\]

(4.5)

We turn to contributions to \( Y(x_0; m, n) \) from terms in (4.1). Pick \( \hat{\chi} = (1/2)(\chi_a + \chi') \) and

\[
X := \max_{v \in S_1(x_0; m, n)} \max_{w \in S_2(x_0; m, n)} \frac{\left| \tau(v, w) - \mathbb{E}\tau(v, w) \right|}{|w-v|\hat{\chi}}. 
\]

By the fact that \( \hat{\chi} > \chi_a \), for some \( C_4 \) and \( C_5 \),

\[
\mathbb{E}e^{\alpha X} \leq \sum_{v \in S_1(x_0; m, n)} \sum_{w \in S_2(x_0; m, n)} \mathbb{E}\left( \exp\left( \alpha \left| \frac{\tau(v, w) - \mathbb{E}\tau(v, w)}{|w-v|\hat{\chi}} \right| \right) \right) 
\]

\[
\leq C_4 |S_1(x_0; m, n)|^2 
\]

\[
\leq C_5 m^{2(d-1)}. 
\]

(4.6)

Since \( \alpha > 0 \) and \( X \) is positive, we may use Jensen’s inequality to get

\[
e^{\alpha \|X\|^2} = 1 + \alpha \|X\|^2 + \sum_{n=2}^{\infty} \frac{(\alpha \|X\|^2)^n}{n!} 
\]

\[
\leq 1 + \alpha \|X\|^2 + \mathbb{E} \sum_{n=2}^{\infty} \frac{(\alpha X)^n}{n!} 
\]

\[
\leq \alpha \|X\|^2 + \mathbb{E} e^{\alpha X}.
\]
Because $e^{\alpha t} \geq 2\alpha t$ for all $t \in \mathbb{R}$, it cannot be that $\alpha \|X\|_2$ is the maximum of the two terms on the right-hand side of (4.6). Thus an upper bound is $2E e^{\alpha X}$, and taking logarithms of both sides, we find $\|X\|_2 \leq \frac{1}{\alpha} \log 2E e^{\alpha X}$. So $\|X\|_2 \leq C_6 \log m$ for some $C_6$. Let

$$X' := \max_{v \in S_1(x_0; m, n)} \max_{w \in S_2(x_0; m, n)} |\tau(v, w) - E\tau(v, w)|.$$ 

Since $|w - v| \leq 2n$ for all $v \in S_1(x_0; m, n)$ and $w \in S_2(x_0; m, n)$, $X' \leq C_7 n^{\hat{X}}$. Therefore, $\|X'\|_2 \leq C_8 n^{\hat{X}}$. We finish by putting this together with (4.4) and (4.5),

$$\|Y(x_0; m, n)\|_2 \leq C_3 n^{1-\kappa} m^{\kappa} + C_9 n^{\hat{X}}.$$ 

□

To end the section, we give one general lemma about random variables. Denote by $I(A)$ the indicator function of the event $A$.

**Lemma 4.3.** Let $X$ and $Y$ be random variables with $\|X\|_4, \|Y\|_4 < \infty$, and let $B$ be an event such that

$$(X - Y) I(B) = 0 \quad \text{almost surely.}$$

Then

(4.7) \quad |\text{Var } X - \text{Var } Y| \leq (\|X\|_4 + \|Y\|_4)^2 \mathbb{P}(B^c)^{1/4}.

**Proof.** Let $\tilde{X} = X - \mathbb{E}X$ and $\tilde{Y} = Y - \mathbb{E}Y$. The left-hand side of (4.7) equals

$$\|\tilde{X}\|_2^2 - \|\tilde{Y}\|_2^2 = \|\tilde{X}\|_2 - \|\tilde{Y}\|_2 ||\tilde{X}\|_2 + ||\tilde{Y}\|_2$$

$$\leq \|X - Y\|_2 (\|X\|_2 + \|Y\|_2)$$

$$\leq \|(X - Y) I(B^c)\|_2 (\|X\|_4 + \|Y\|_4)$$

$$\leq \|X - Y\|_4 (\|X\|_4 + \|Y\|_4) \mathbb{P}(B^c)^{1/4},$$

which implies the lemma. □

4.2. Cylinder construction. Pick $x_0$ of unit norm and $H_0$ a hyperplane as in Definition 3.1. Fix an orthonormal basis $x_1, \ldots, x_{d-1}$ of $H_0$. Let $T_1(x_0; n) = \tau(0, nx_0)$, $T_2(x_0; n, \xi') = \tau(4n^{\hat{X}} x_1, nx_0 + 4n^{\hat{X}} x_1)$ and

$$\delta T(x_0; n, \xi') = T_1(x_0; n) - T_2(x_0; n, \xi').$$

The idea will be to give a lower bound for the variance of $\delta T$ (Section 4.2.1) and then an upper bound (Section 4.2.2). Comparing them, we obtain the desired inequalities, (2.3) and (3.3). This idea was introduced by Licea, Newman and Piza in [14] and also used in [9] and [17].
4.2.1. Lower bound on $\text{Var} \delta T$. We will now assume that

$$
(4.8) \quad \xi_a < 1 \quad \text{and} \quad \chi_b > 0
$$

so that we can choose $\xi'$ and $\chi''$ such that

$$
(4.9) \quad \xi_a < \xi' < 1 \quad \text{and} \quad 0 < \chi'' < \chi_b.
$$

**Proposition 4.4.** Assume (4.8). For each $\xi'$ and $\chi''$ chosen as in (4.9), there exists $C = C(\xi', \chi'')$ such that for all $n$,

$$
\text{Var} \delta T(x_0; n, \xi') \geq C n^{2 \chi''}.
$$

**Proof.** Define $C_1$ as the set of points in $\mathbb{R}^d$ at most $\ell_{\infty}$ distance $n^{\xi'}$ away from the line segment connecting 0 to $nx_0$. Define $C_2$ as the set of points at most $\ell_{\infty}$ distance $n^{\xi''}$ away from the line segment connecting $4n^{\xi'}$ to $nx_0 + 4n^{\xi'}$. Let $T_1(x_0; n)$ and $T_2(x_0; n)$ be as follows:

1. $T_1(x_0; n)'$ is the passage time from 0 to $nx_0$ using only edges with endpoints in $C_1$.
2. $T_2(x_0; n)$ is the passage time from $4n^{\xi'}$ to $nx_0 + 4n^{\xi'}$ using only edges with endpoints in $C_2$.

Let $B$ be the event \{ $T_1(x_0; n) = T_1(x_0; n)'$ and $T_2(x_0; n, \xi') = T_2(x_0; n, \xi')'$ \}. Note that if $T_1(x_0; n) \neq T_1(x_0; n)'$, then $D(0, nx_0) \geq n^{\xi'}$. A similar statement holds for $T_2(x_0; n, \xi')$ and $T_2(x_0; n, \xi')'$. Therefore, $\mathbb{P}(B^c) \leq 2 \mathbb{P}(D(0, nx_0) \geq n^{\xi'})$. Picking $\xi'' = (1/2)(\xi' + \xi_a)$, so that $\xi_a < \xi'' < \xi' < 1$, we find from the definition of $\xi_a$ [from (2.1)] that there exists $C_1 > 0$ such that for all $n$, $\mathbb{P}(D(0, nx_0) \geq n^{\xi''}) \leq e^{-C_1 n^{\xi' - \xi''}}$. Therefore

$$
(4.10) \quad \mathbb{P}(B^c) \leq 2 e^{-C_1 n^{\xi' - \xi''}}.
$$

By Lemma 4.3 with $X = \delta T(x_0; n, \xi')$ and $Y = \delta T(x_0; n, \xi')' := T_1(x_0; n)' - T_2(x_0; n, \xi')'$:

$$
\text{Var} \delta T(x_0; n, \xi') - \text{Var} \delta T(x_0; n, \xi')' \\
\geq -\left( \| \delta T(x_0; n, \xi') \|_4 + \| \delta T(x_0; n, \xi')' \|_4 \right)^2 \mathbb{P}(B^c)^{1/4}
\geq -C_2 n^2 e^{-C_1/4 n^{\xi' - \xi''}}
$$

for some $C_2$. Here we have used inequality (4.10) and that each $\delta T$ is a difference of two passage times, each of which has $L^4$ norm bounded above by $Cn$ (compare, e.g., to a deterministic path). Therefore, there exists $C_3$ such that for all $n$,

$$
(4.11) \quad \text{Var} \delta T(x_0; n, \xi') \geq \text{Var} \delta T(x_0; n, \xi')' - C_3.
$$
But $\delta T(x_0; n, \xi')$ is the difference of i.i.d. random variables distributed as $T_1(x_0; n)$, so
\begin{equation}
\Var \delta T(x_0; n, \xi') = 2 \Var T_1(x_0; n).
\end{equation}

By exactly the same argument as that given above, we can find $C_4$ such that for all $n$,
\[ \Var T_1(x_0; n) \geq \Var T_1(x_0; n) - C_4 = \Var \tau(0, nx_0) - C_4. \]

Using the definition of $\chi''$, we can find another $C_5$ such that for all $n$, $\Var \tau(0, nx_0), n) \geq C_5 n^{2\chi''}$. Combining this with (4.12) and (4.11), we complete the proof. □

### 4.2.2. Upper bound on $\Var \delta T$

In this section we continue to assume (4.8) and we work with the same choice of $\xi'$ that satisfies (4.9). We will prove the following.

**Proposition 4.5.** Assume (4.8) and that (3.2) holds for some $C$, $\varepsilon_{x_0}$ and $\kappa$. For each $\beta$ satisfying $\xi' < \beta < 1$ and each $\chi' > \chi_a$, there exists $C = C(\beta, \chi')$ such that for all $n$,
\[ \Var \delta T(x_0; n, \xi') \leq C n^{2\beta(1-\kappa) + 2\xi' \kappa} + C n^{2\beta \chi'}. \]

**Proof.** Define the hyperplanes
\[ H_1 = n^\beta x_0 + H_0 \quad \text{and} \quad H_2 = (n - n^\beta) x_0 + H_0. \]

Let $C_1$ and $C_2$ be as in the proof of the lower bound. For two points $a$ and $b$ in $\mathbb{R}^d$, let $S(a, b)$ be the set of finite paths $P$ from $a$ to $b$ (or their closest lattice points) such that for both $i = 1$ and 2, $P \cap H_i \cap [C_1 \cup C_2] \neq \emptyset$. Define $T_1(x_0; n)^{''}$, $T_2(x_0; n, \xi')^{''}$ as follows:

1. $T_1(x_0; n)^{''}$ is the minimum passage time of all paths in $S(0, nx_0)$.
2. $T_2(x_0; n, \xi')^{''}$ is the minimum passage time of all paths in $S(4n^{\xi'} x_1, nx_0 + 4n^{\xi} x_1)$.

Again we set $B$ equal to the event $\{T_1(x_0; n) = T_1(x_0; n)^{''}$ and $T_2(x_0; n, \xi') = T_2(x_0; n, \xi')^{''}\}$. Because $B^{c}$ implies that $D(0, nx_0) \geq n^{\xi'}$, we may choose $C_1$ such that for all $n$,
\[ \mathbb{P}(B^c) \leq 2e^{-C_1 n^{\xi'}}, \]

where $\xi'' = (1/2)(\xi' + \xi_a)$. Therefore, we can argue exactly as in the previous section to find $C_2$ such that for all $n$,
\begin{equation}
\Var \delta T(x_0; n, \xi') \leq \Var \delta T(x_0; n, \xi')^{''} + C_2,
\end{equation}
where $\delta T(x_0; n, \xi')^{''} = T_1(x_0; n)^{''} - T_2(x_0; n, \xi')^{''}$.

For almost every passage time realization, we may define a path $\gamma_1 \in S(0, nx_0)$ (in a measurable and deterministic way when there are not unique geodesics).
from 0 to \(nx_0\) so that \(\tau(\gamma_1) = T_1(x_0; n)''\) and \(\gamma_2 \in S(4n^{\xi'} x_1, nx_0 + 4n^{\xi'} x_1)\) such that \(\tau(\gamma_2) = T_2(x_0; n, \xi'')\). Let \(a_1\) be the last lattice point on \(\gamma_2\) before it intersects \(H_1 \cap (C_1 \cup C_2)\) and \(a_2\) the last lattice point of \(\gamma_2\) before it intersects \(H_2 \cap (C_1 \cup C_2)\). Similarly let \(a_1'\) be the last lattice point of \(\gamma_1\) before it intersects \(H_1 \cap (C_1 \cup C_2)\) and \(a_2'\) the last lattice point of \(\gamma_1\) before it intersects \(H_2 \cap (C_1 \cup C_2)\). Write \(s_1\) for the piece of \(\gamma_2\) (seen as an oriented path) from \(4n^{\xi'} x_1\) to \(a_1, t_2\) for the piece of \(\gamma_2\) from \(a_1\) to \(a_2\) and \(s_2\) for the piece of \(\gamma_2\) from \(a_2\) to \(nx_0 + 4n^{\xi'} x_1\). Similarly, write \(s_1'\) for the piece of \(\gamma_1\) from 0 to \(a_1'\) and \(s_2'\) for the piece of \(\gamma_1\) from \(a_2'\) to \(nx_0\). By definition of \(T_1(x_0; n)''\), we have the following almost surely:

\[
T_1(x_0; n)'' \leq \tau(0, a_1) + \tau(t_2) + \tau(a_2, ne_1)
\]

(4.14)

Set \(H_3 = nx_0 + H_0\), and let \(C\) be the set of all points in \(\mathbb{R}^d\) that are \(\ell_\infty\) distance at most \(5n^{\xi''}\) from the line segment connecting 0 to \(nx_0\). Last, let \(V_i = H_i \cap C\) for \(i = 0, \ldots, 3\) and

\[
X_i(n, \xi', \beta) = \max_{v_1, v_2 \in V_{2i}} \|\tau(v_1, w_1) - \tau(v_2, w_2)\|, \quad i = 0, 1.
\]

Using this notation and (4.14), we can give an upper bound for \(T_1(x_0; n)''\) of

\[
T_1(x_0; n)'' \leq T_2(x_0; n, \xi'')'' + X_0(n, \xi', \beta) + X_1(n, \xi', \beta).
\]

To bound \(T_2(x_0; n, \xi'')''\), we can similarly write

\[
T_2(x_0; n, \xi'')'' \leq \tau(4n^{\xi'} x_1, a_1') - \tau(s_1')
\]

\[
+ \tau(a_2', nx_0 + 4n^{\xi'} x_1) - \tau(s_2') + T_1(x_0; n)'.
\]

Therefore, \(T_2(x_0; n, \xi'')'' \leq X_0(n, \xi', \beta) + X_1(n, \xi', \beta) + T_1(x_0; n)''\). Putting these together,

\[
|\delta T(x_0; n, \xi'')''| \leq X_0(n, \xi', \beta) + X_1(n, \xi', \beta) \quad \text{almost surely}
\]

and consequently

\[
\operatorname{Var} \delta T(x_0; n, \xi'')'' \leq \|\delta T(x_0; n, \xi'')''\|_2^2 \leq 2\|X_0(n, \xi', \beta)\|_2^2 + \|X_1(n, \xi', \beta)\|_2^2.
\]

The variables \(X_0\) and \(X_1\) are identically distributed, so \(\operatorname{Var} \delta T(x_0; n, \xi'')'' \leq 4\|X_0(n, \xi', \beta)\|_2^2\). Finally, we combine with (4.13) to get

(4.15) \quad \operatorname{Var} \delta T(n, \xi') \leq 4\|X_0(n, \xi', \beta)\|_2^2 + C_2.

The last step is to invoke Proposition 4.2. The variable \(X_0(n, \xi', \beta)\) is the same as \(X(x_0; 5n^{\xi'}, n^\beta)\) there. Because \(\beta\) was chosen to be larger than \(\xi'\), the condition \(5n^{\xi'} \leq \frac{5n^{\xi'}}{2\sqrt{d-1}} n^\beta\) holds for large \(n\). Thus there exists \(C_3\) such that for all large \(n\),

\[
\|X_0(n, \xi', \beta)\|_2^2 \leq C_3n^{2\beta(1-\kappa)}n^{2\xi'\kappa} + C_3n^{2\beta\kappa'},
\]

where \(\kappa\) is from the statement of this proposition. With (4.15), this completes the proof. □
4.3. **Proof of Theorem 2.1.** We now prove Theorem 2.1. Assume that $\chi_a = \chi_b = \chi > 0$. Further, we may assume $\xi_a < 1$ because if $\xi_a = 1$, the relation holds by the bound $\chi \leq 1/2$; see Remark 1.

Choose $|x_0| = 1$ such that (3.2) holds for some $\varepsilon_{x_0}$ and $C_{x_0} > 0$ for $\kappa = 2$. (The existence of such a point is proved in [5], Proposition 5.1.) From the previous two sections, for each choice of $\chi', \chi'', \xi'$ and $\beta$ satisfying

\begin{equation}
0 < \chi'' < \chi < \chi' \quad \text{and} \quad \xi_a < \xi' < \beta < 1,
\end{equation}

there exist constants $C_i = C_i(\chi', \chi'', \xi', \beta) \ (i = 1, 2)$ such that for all $n$,

\begin{equation}
C_1 n^{2\chi''} \leq \text{Var} \delta T(n, \xi') \leq C_2 n^{-2\beta + 4\xi'} + C_2 n^{2\beta \chi'}.
\end{equation}

For any $\beta$ with $\xi' < \beta < 1$, we may choose $\chi'' = \chi''(\beta)$ and $\chi' = \chi'(\beta)$ that satisfy (4.16) and are so close to $\chi$ that $2\beta \chi' < 2\chi''$. For such a choice of $\chi''$ and $\chi'$ we then have

\begin{equation}
(1/2)C_1 n^{2\chi''} \leq C_2 n^{-2\beta + 4\xi'} \quad \text{for all large } n
\end{equation}

and, therefore, $\chi'' \leq -\beta + 2\xi'$. Taking $\beta \uparrow 1$ and noting that $\chi''(\beta) \uparrow \chi$, we find $\chi \leq -1 + 2\xi'$. This is true for all $\xi' > \xi_a$, so $\chi \leq -1 + 2\xi_a$.

**Acknowledgments.** We are very grateful to S. Chatterjee for his advice and comments on the presentation in an earlier version of the paper. Also we thank G. Ben Arous and C. Newman for suggestions on the Introduction and A. Sapozhnikov for comments and careful readings of the paper.
