Abstract

We study (analytic) finite-size corrections in the dense polymer model on the strip by perturbing the critical Hamiltonian with irrelevant operators belonging to the tower of the identity. We generalize the perturbation expansion to include such representations. In perturbation theory to include such representations. In particular, the corrections do not depend on these parameters nor even on the presence of Jordan cells. Though the corrections themselves are not universal, the ratios are universal and correctly reproduced by the conformal perturbative approach, to first order.

1. Introduction

Universality, scaling, and finite-size corrections for critical systems have attracted much attention in recent decades \cite{12, 13, 14, 15, 16}. Although many theoretical results are now known about the critical exponents and universal relations among the leading critical amplitudes, not much information is available on ratios among the amplitudes in finite-size correction terms \cite{6}. New universal amplitude ratios have been recently presented for the Ising model \cite{6}. In this paper, we compute finite-size corrections in the critical dense polymer model \cite{9}, and compare them with the results obtained in perturbation theory. Compared to previous analyses, the new feature here is the presence of indecomposable representations in the conformal spectrum \cite{6, 11, 12}, which first requires to adapt the perturbation theory to include such representations. In particular it raises the question as to whether the finite-size corrections depend on their indecomposability parameters \cite{12, 13, 14, 15, 16, 17}.

Conformal invariance implies that on an infinitely long strip of finite width \( N \), the eigenstates of the critical transfer matrix, associated to conformal states, have energies that scale with \( N \) like \( N^{1/2} \)

\begin{equation}
E_n(N) = N f_b + f_s + \frac{\pi \zeta (\Delta_n - c/24)}{N} + O(N^{-2}), \quad (1)
\end{equation}

where the bulk free energy density \( f_b \), the surface free energy \( f_s \), and the anisotropy factor \( \zeta \) are non-universal constants; in contrast, the central charge \( c \) and the weights \( \Delta_n \) of the conformal eigenstates, are universal (although boundary dependent for \( \Delta_n \)).

Higher order correction terms in (1) are nonuniversal; however it has been suggested recently \cite{6}, and partially checked for the Ising universality class \((c = 1/2)\), that the asymptotic expansion of the critical eigenvalues has the form \((n = 0)\) will refer to the groundstate

\begin{equation}
E_n(N) = N f_b + f_s + \sum_{p=1}^{\infty} \frac{a_p^{(n)}}{N^{2p-1}}, \quad (2)
\end{equation}

and that the amplitude ratios \( a_p^{(n)}/a_p^{(0)} \) are universal and depend only on the boundary conditions \cite{6, 11, 12}. The case \( p = 1 \) readily follows from (1).

For critical dense polymers, it is not difficult to see from the results of \cite{6} that the finite-size energy levels have an asymptotic expansion like in (2). The general calculation of all coefficients is a tedious exercise, which can however be completed for an infinite number of levels (among these, the lowest-lying levels, as well as the lowest-lying logarithmic pairs, in each representation). Moreover we check that the first coefficients \( a_2^{(n)} \) match the perturbative values, and that the ratios \( a_2^{(n)}/a_2^{(0)} \) are universal.

2. Critical dense polymers

We consider the model of critical dense polymers on a square grid, as formulated in \cite{9}. The degrees of freedom are localized on the elementary faces of the lattice, which can be in two different configurations, see Eq. (2.1) of \cite{9}. The model on a strip, of width \( N \) and height \( 2M \), has a double-row transfer matrix \( D(u) \). The partition function

\[ Z(N, M) = \text{Tr}_b \left( D(u)^N \right) \]
is given by
\[
Z_{N,M} = \text{Tr} \mathbf{D}(u)^M = \sum_n e^{-2M E_n(N,u)},
\]
where the sum is over all eigenvalues of \(\mathbf{D}(u)\), written as \(e^{-2E_n(N,u)}\); \(u\) is a spectral parameter related to the anisotropy factor by \(\zeta = \sin 2u\).

The configuration space on which the transfer matrix acts can be divided into sectors \(\mathcal{L}_{N,\ell}\), labelled by an integer \(\ell \geq 0\), of the same parity as \(N\). The integer \(\ell\) is the number of defect lines, and can be seen as fixing a specific boundary condition. The range of \(\ell\) is finite when \(N\) is finite, but will be considered as unbounded in the limit \(N \to \infty\). It was found in \[6\] that the transfer matrix is diagonalizable when restricted to each sector separately, although analytic and numerical analyses indicated that it is not in the full space when \(N\) is even. This was confirmed in \[10, 19\], where it was shown that the sectors \(\ell\) and \(\ell + 2\), for \(\ell = 0 \mod 4\), are linked up by rank 2 Jordan blocks, while there are no Jordan cells when \(N\) is odd.

All eigenvalues have been determined in \[8\], for any finite value of \(N\). They are given by
\[
E_n = -\frac{1}{2} \sum_{j=1}^{N-2} \log \left[ (1 + \zeta \varepsilon_j \sin \frac{\pi j}{2N})(1 + \zeta \mu_j \sin \frac{\pi j}{2N}) \right],
\]
where the summation includes the integers \(j\) with the same parity as \(N\). The eigenvalues also depend on parameters \(\varepsilon_j, \mu_j\) equal to \(\pm 1\), although not all choices of \(\varepsilon_j, \mu_j\) are allowed. Exactly which sequences of \(+1, -1\) correspond to actual eigenvalues, and for which sector, are given by the selection rules conjectured in \[9\], and proved very recently in \[21\]. What we need is summarized below.

A main result from \[8\] is that the set of eigenvalues of the transfer matrix in the sector \(\mathcal{L}_{N,\ell}\) is such that it leads, through \[11\], to a set of conformal weights \(\Delta_n\) whose values and degeneracies exactly match those of the highest weight representation \(V_{1,s}\) of weight \(h_{1,s} = \frac{s^2 - 1}{8}\), with \(s = \ell + 1\). As a representation of the Virasoro algebra, \(V_{1,s}\) is believed to be the quotient of the highest weight Verma module \(V_{1,s}\) by the singular vector at level \(s\) \[19\].

The overall groundstate \(E_0\), found in \(\mathcal{L}_{N,0}\) or \(\mathcal{L}_{N,1}\), corresponds to all \(\varepsilon_j = \mu_j = 1\) in \[8\]. From the Euler-MacLaurin summation formula, the asymptotic expansion of \(E_0\) takes the form \[2\] with the coefficients
\[
a_p^{(0)} = \frac{\pi^{2p-1} B_{2p}(\alpha)}{(2p)!} \lambda_{2p-1}(\zeta), \quad \alpha = \frac{N}{2} \mod 1,
\]
where \(B_n(x)\) are the Bernoulli polynomials, \(\alpha = 0, \frac{1}{2}\), and \(\lambda_{2p-1}(\zeta)\) are polynomials of degree \(2p - 1\), obtained from the following expansion,
\[
\log (1 + \zeta \sin x) = \sum_{n=1}^{\infty} \frac{\lambda_n(\zeta)}{n!} x^n.
\]

The first few odd order polynomials read \(\lambda_1(\zeta) = \zeta, \lambda_3(\zeta) = 2\zeta^3 - \zeta, \lambda_5(\zeta) = 24\zeta^5 - 20\zeta^3 + \zeta\), see also \[21\].

For \(p = 1\) in particular, one finds \(\Delta_0 - \epsilon/24 = 1/12\) for \(N\) even and \(-1/24\) for \(N\) odd. Assuming \(c = -2\), this gives \(\Delta_0 = h_{1,1} = 0\) for \(N\) even, and \(\Delta_0 = h_{1,2} = -1/8\) for \(N\) odd.

For \(p = 2\) one finds from the previous formula
\[
a_2^{(0)} = \frac{\pi^3}{6} (\Delta_0^2 - \frac{1}{240}) \lambda_3(\zeta).
\]

The excited levels are obtained by switching the \(\varepsilon_j, \mu_j\) from \(+1\) to \(-1\) in a way allowed by the selection rules \[8, 21\]. The specific levels we will consider here are the two lowest-lying levels in each sector \(\mathcal{L}_{N,\ell}\), denoted \(E_0^{(\ell)}\) and \(E_1^{(\ell)}\), for all \(\ell \geq 1\) except \(\ell = 2\) (which is somewhat special and requires a separate treatment; the following checks however work for them too). They are non-degenerate (within their sector) and are obtained by setting to \(-1\) the parameters \(\mu_j\) with the following indices (keeping those of the appropriate parity),
\[
1 \leq j \leq \ell - 2 \quad \text{for } E_0^{(\ell)},
\]
\[
1 \leq j \neq \ell - 2 \leq \ell \quad \text{for } E_1^{(\ell)}.
\]

Working out the asymptotic expansion of \(E_1^{(\ell)}\) for \(r = 0, 1\), yields the first coefficients (with no assumption on \(c\))
\[
a_1(E_1^{(\ell)}) = \pi (h_{1,s} + r + \frac{1}{12}) \lambda_1(\zeta),
\]
and
\[
a_2(E_1^{(\ell)}) = \frac{\pi^3}{6} (h_{1,s}^2 - \frac{1}{240}) \lambda_3(\zeta),
\]
\[
a_2(E_1^{(\ell)}) = \frac{\pi^3}{6} (h_{1,s}^2 + 6h_{1,s} + \frac{119}{240}) \lambda_3(\zeta).
\]

Before comparing them with the perturbative approach, it is useful to know where the Jordan blocks appear when one considers the full configuration space, namely the union of all sectors.

As mentioned above, Jordan cells appear only for \(N\) even, in which case the full configuration space is given by \(\cup_{\ell \geq 0, \text{even}} \mathcal{L}_{N,\ell}\). It turns out that within each sector, the eigenstates are generically non-degenerate, implying that the transfer matrix is diagonalizable in each sector separately; however every sector \(\mathcal{L}_{N,\ell}\) has a subset of eigenstates which are pairwise degenerate with eigenstates of \(\mathcal{L}_{N,\ell-2}\), while the complementary subset is pairwise degenerate with eigenstates of \(\mathcal{L}_{N,\ell+2}\); these double degeneracies occur for all values of \(N\) (even) and \(\zeta\).

In the conformal limit (the order \(N^{-1}\) in the expansion of the eigenvalues), the degeneracy of the eigenstates increases. For \(N\) odd, each sector \(\ell\) odd carries an irreducible highest weight representation \(V_{1,\ell+1}\). For \(N\) even, it is believed \[8, 11, 13\] that the pairs of sectors \(\ell\) and \(\ell + 2\), for \(\ell = 0 \mod 4\), and their associated representations \(V_{1,\ell+1}\) and \(V_{1,\ell+3}\), are tied together by rank 2 Jordan cells to form staggered modules \[12, 13, 14\].
3. Conformal perturbation theory

The finite-size corrections in \[ \mathcal{R}_{1+\ell/2} \] can in principle be computed in perturbation theory [22]. In general, the critical lattice Hamiltonian will contain correction terms to the fixed-point Hamiltonian \( H_c = \frac{1}{\Delta} (L_0 - \Delta^2) \),

\[
H = \zeta H_c + \sum_k g_k \int_0^N \varphi_k(v) \, dv,
\]

where the \( \varphi_k \) are irrelevant quasi-primary fields, and \( g_k \) are non-universal constants. On general grounds, a perturbation \( \varphi \) with scaling dimension \( x_\varphi \) brings a first-order correction to the energy proportional to \( N^{1-x_\varphi} \).

Fields in the tower of the identity are available in any conformal theory. On the strip, the lowest contributing field is \( \varphi = L_{-2}^2(v) \), of dimension 3 [22]; it corrects the conformal energies by a \( N^{-3} \) term, and should reproduce the first correction coefficient \( a_2^{(n)} \) in [2].

\footnote{The correct quasi-primary combination of dimension 4 is \( L_{-2}^2(v) - \frac{3}{2} L_{-1}^2(v) \); however the terms \( L_{-n}^2(v) \) for \( n \geq 3 \) give no contribution to any order in perturbation [23].} 

Perturbation techniques have been studied for a long time, and successfully applied in concrete models [24]. Write \( H = H_0 + gV \). A basic result states that the first-order correction to the energy \( E_{c,n} \) of a non-degenerate eigenstate \( |n\rangle \) of \( H_0 \) is given by \( \langle n|gV|n\rangle \). Here it is sufficient that the state \( |n\rangle \) be non-degenerate within its own representation since \( \varphi \) preserves each representation.

This scheme can be readily applied to the critical dense polymer model when \( N \) is odd, or to the two lowest-lying states in the indecomposable representations \( \mathcal{R}_k \) (\( \xi \) and \( L_{-1}\xi \)) when \( N \) is even, but should be adapted for states in Jordan cells. In addition the representations \( \mathcal{R}_k \) carry an intrinsic parameter \( \beta_k \), which may affect the corrections.

It has been appropriately emphasized in [16, 11] that the conformal states should be equipped with a scalar product for which the conformal Hamiltonian is hermitian. When the Hamiltonian is not diagonalizable, this bilinear form cannot be positive definite and differs from the canonical scalar product usually used in the lattice configuration space. For a typical rank 2 Jordan cell in the subset \( S_2 \subset \mathcal{R}_k \), one can take the scalar product to be such that \( \langle \phi|\varphi \rangle = 0 \), \( \langle \phi|\psi \rangle = \langle \psi|\phi \rangle = 0 \), \( \langle \psi|\psi \rangle = 0 \), and so \( \beta = 0 \) if \( \langle \phi,\psi \rangle \) is the lowest logarithmic pair of \( \mathcal{R}_k \), otherwise \( \beta \) is a calculable multiple of \( \beta_k \) for a descendant logarithmic pair [11]. For states in \( S_1 \), the usual scalar product is used.

Assume that \( \phi,\psi \) are the conformal states of a non-degenerate logarithmic pair (only pair at their level),

\[
(H_0 - \lambda_0)\phi = 0, \quad (H_0 - \lambda_0)\psi = \phi, \quad (H - \lambda)\Phi = 0, \quad (H - \lambda)\Psi = \Phi.
\]

Expanding in power series in \( g \), \( \lambda = \Delta + g_1 \lambda_1 + \ldots \), \( \Phi = \phi + g_1 \phi_{(1)} + \ldots \), \( \Psi = \psi + g_1 \psi_{(1)} + \ldots \), we obtain at first order the consistency condition \( \langle \phi|V|\phi \rangle = 0 \) and

\[
\beta \lambda_1 = \langle \phi|V|\psi \rangle = \langle \psi|V|\phi \rangle.
\]

Since \( \psi \) is the only state to have a non-zero scalar product with \( \phi \), the r.h.s. is proportional to \( \beta \), and so \( \lambda_1 \) does not depend on \( \beta \).

The required matrix element can be computed by the procedure used in [23] for highest weight representations. To avoid confusions, we denote hereafter by \( (\phi_k,\psi_k) \) the lowest logarithmic pair in \( \mathcal{R}_k \), with conformal weight \( h \). Thus we view the pair \( (\phi,\psi) \) as descendants fields at level \( r \) of \( (\phi_k,\psi_k) \), \( \Delta = h + r \).

The main idea is to compare the chiral 3-point function on a strip of width \( N \),

\[
F_{\psi_k \varphi_{k}}(w_i) = \langle \psi_k(w_1) L_{-2}(w_2) \psi_k(w_3) \rangle_{\text{strip}}
\]
with its expression in the operator formalism. The previous correlator is first computed on the upper-half plane and then conformally transformed to the strip. It can be shown that the logarithmic part of $F_{\psi,k\phi,\hat{\psi},\lambda}$ is

$$F_{\psi,k\phi,\hat{\psi},\lambda}(w) = \beta_k \left\{ \log \frac{2a}{z_1} - 2 \log \left( 1 - \frac{2a}{z_1} \right) \right\} F_{\pi\phi,\pi}(z_1),$$

where $F_{\pi\phi,\pi}$ is the strip correlator [17] with $\psi$ replaced by a primary field $\pi$ of the same weight $h$ as $\psi$, and where $z_i = \exp(\pi w_i/N)$ relates the planar variables to the strip coordinates. The calculation of $F_{\pi\phi,\pi}$ is standard but requires the transformation law of the descendant field $L^2_{2d}(w)$. Using the results of [22] on the transformation laws of general descendant fields, one finds the following explicit function of $x = z_3/z_1$ and $y = z_3/z_2$,

$$F_{\pi\phi,\pi}(z_1) = \left( \frac{\pi}{N} \right)^{2h+4} \frac{(xy)^h}{(1-xy)^{2h}} \times \left\{ h(h+2) \left( \frac{1-x^2}{(1-x^2)^2(1-y^2)^2} - 3h \left( \frac{1-x^2}{(1-x^2)^2} + \frac{1-e^\beta}{2} \right) \right) \right\} \frac{1}{12} \left( \frac{1-x^2}{(1-x^2)^2} + \frac{e^\beta}{24} \right).$$

In the operator formalism, and for $w = u + iv$, the correlator is

$$F_{\psi,k\phi,\hat{\psi},\lambda} = \langle 0 | \hat{\psi}(0,v_1) T^{u_1-u_2} \hat{\phi}(0,v_2) T^{u_2-u_3} \hat{\psi}(0,v_3) | 0 \rangle,$$

with the transfer matrix $T = e^{-\pi L_0/N}$. Inserting a complete set of states of $R_k$, the contribution coming from the pair $(\phi, \psi)$ reads

$$F \sim \langle 0 | \hat{\psi}(0,v_1) | T^{u_1-u_2} P \hat{\phi}(0,v_2) P T^{u_2-u_3} \hat{\psi}(0,v_3) | 0 \rangle,$$

where

$$P = \frac{|\psi\rangle \langle \phi|}{\beta} + \frac{|\phi\rangle \langle \psi|}{\beta} - \gamma \frac{|\phi\rangle \langle \phi|}{\beta^2}$$

is a projector on the subspace spanned by $\phi, \psi$, namely $P \psi = \psi$, $P \phi = \phi$ and $P |n\rangle = 0$ for any other state $|n\rangle$. Using the action of the transfer operator, namely $e^{\pm L_0} |\phi\rangle = e^{\pm \Delta} |\phi\rangle$ and $e^{\pm L_0} |\psi\rangle = e^{\pm \Delta} (|\psi\rangle + x |\phi\rangle)$, we find that [21] has a term quadratic in the $u$’s,

$$\frac{\pi^2}{\beta^2 N^2} e^{-\pi \Delta(u_1-u_3)} (u_1-u_2)(u_2-u_3) \times \langle 0 | \hat{\psi}(0,v_1) | \phi \rangle \langle \phi \mid \hat{\phi}(0,v_2) | \phi \rangle \langle \phi \mid \hat{\psi}(0,v_3) | 0 \rangle.$$ (23)

As $u \sim \log z$, this term would require a corresponding logarithm term in the 3-point function $F_{\psi,k\phi,\hat{\psi},\lambda}$, which does not exist. We thus have $\langle \phi \mid \hat{\phi}(0,v_2) | \phi \rangle = 0$, which fulfills the consistency condition we found in perturbation theory.

Looking now at the terms linear in the $u$’s, we find

$$-\frac{\pi}{\beta^2 N} e^{-\pi \Delta(u_1-u_3)} \times \left\{ (u_1 - u_2)(0| \hat{\psi}_k(0,v_1) | \phi \rangle \langle \phi \mid \hat{\phi}(0,v_2) | \phi \rangle \langle \phi \mid \hat{\psi}_k(0,v_3) | 0 \rangle + (u_2 - u_3)(0| \hat{\psi}_k(0,v_1) | \phi \rangle \langle \phi \mid \hat{\phi}(0,v_2) | \phi \rangle \langle \phi \mid \hat{\psi}_k(0,v_3) | 0 \rangle \right\}.$$ (24)

The dependence in $u_2$ must vanish, which implies the equality $\langle \phi \mid \hat{\phi}(0,v_2) | \phi \rangle = \langle \psi \mid \hat{\phi}(0,v_2) | \phi \rangle$, so that a single term remains,

$$-\frac{\pi}{\beta^2 N} e^{-\pi \Delta(u_1-u_3)} (u_1-u_3) \times$$

$$\langle 0 | \hat{\psi}_k(0,v_1) | \phi \rangle \langle \phi \mid \hat{\phi}(0,v_2) | \psi \rangle \langle \phi \mid \hat{\psi}_k(0,v_3) | 0 \rangle.$$ (25)

Since $e^{-\pi \Delta(u_1-u_3)} \sim z_3/z_1$, a comparison with [18] implies, provided the pair $(\phi, \psi)$ is not degenerate, that the product of the three matrix elements in the previous equation equals the coefficient of $(z_3/z_1)^\Delta = (xy)^\Delta$ in $\beta^2 \beta_k F_{\pi\phi,\pi}$, and does not depend on $v_2$.

Repeating the same steps for the 2-point function

$$F_{\psi,k\phi,\hat{\psi},\lambda}(w, u_3) = \langle \psi_k(u_1) \psi_k(u_3) \rangle,$$

we obtain similarly that its logarithmic part is given by

$$F_{\psi,k\phi,\hat{\psi},\lambda}(w) = \beta_k \left\{ \log \frac{z_3}{z_1} - 2 \log \left( 1 - \frac{z_3}{z_1} \right) \right\} F_{\pi\phi,\pi}(z_1),$$

where $F_{\pi\phi,\pi}$ is the strip 2-point function for a primary field of weight $h$,

$$F_{\pi\phi,\pi}(z_1) = \left( \frac{\pi}{N} \right)^{2h} \frac{(z_1z_3)^h}{(z_1 - z_3)^{2h}};$$

a function of the single argument $xy$.

Comparing this function with its corresponding expression in the operator formalism, we can conclude that the product $\langle \psi_k(0,v_1) | \phi \rangle \langle \phi \psi_k(0,v_3) | 0 \rangle$ is equal to the coefficient of $(z_3/z_1)^\Delta$ in $\beta_k F_{\pi\phi,\pi}$.

Combining the above results on the triple and double products, we obtain that their ratio yields

$$\langle \phi \mid \hat{\phi}(0,v_2) | \psi \rangle = \langle \phi \mid \hat{\phi}(0,0) | \psi \rangle = \frac{F_{\psi,k\phi,\hat{\psi},\lambda}(x,y)}{F_{\pi\phi,\pi}(x,y)}.$$ (29)

This formula shows that the first correction $\lambda_1$ to the conformal energy of $\psi$ can be computed as if $\psi$ was a (non-degenerate) descendant $|\Delta\rangle$ of a primary field $\pi$,

$$\lambda_1 = \frac{1}{\beta} \langle \phi | V | \psi \rangle = \frac{1}{\beta} \int_0^N dv \langle \phi | \hat{\phi}(0,v) | \psi \rangle = \frac{F_{\psi,k\phi,\hat{\psi},\lambda}(x,y)}{F_{\pi\phi,\pi}(x,y)} = \langle \Delta | V | \Delta \rangle.$$ (30)

Being degenerate with $\psi$, the first correction for $\phi$ is equal to that of $\psi$. Thus all Jordan couplings between sectors for $N$ even can be neglected for the calculation of $\lambda_1$, and each sector $L_{N,\ell}$ can be considered separately, as carrying a highest weight representation $V_{1,\ell}$. Note that the formula (29) requires $h \neq 0$.

At higher orders in perturbation, we have no general argument to show that the same conclusion holds. On
the other hand, we expect that the first order corrections coming from more irrelevant perturbations in the tower of the identity show the same independence to the Jordan structure.

So let \( |\Delta| = |h, r| \) be a non-degenerate, level \( r \) descendant state in a representation of highest weight \( h \). The normalized matrix elements \( C_{\Delta\varphi\Delta} \equiv (N/\pi)^4 \langle \varphi(0,0)|\Delta\rangle \) for \( \varphi = (L^2, h, r) \) can be computed from (28) by using the explicit functions \( F_{\varphi, r\pi} \) and \( F_{\pi, r\varphi} \) above, and reproduce, for \( h \neq 0 \), the results first found in \( 23 \),

\[
C_{\Delta\varphi\Delta} = (h + r) \left( h + r \frac{(2h + r)(5h + 1)}{(h + 1)(2h + 1)} - \frac{2 + c}{12} \right) + \left( c \frac{e}{24} \right)^2 + \frac{11c}{1440} + \frac{r}{30} \left( r^2(5c - 8) - (5c + 28) \right) \delta_{h,0}.
\]

We obtain from this the first correction to the conformal energy of a state \( |\Delta\rangle \) as

\[
g\lambda_1 = \langle \Delta | \Delta \varphi | \Delta \rangle = \frac{g \pi^4}{N^3} C_{\Delta\varphi\Delta}.
\]

We may now apply this to the two lowest levels \( E_0^{(t)} \) and \( E_1^{(t)} \) in each sector \( L_{N,\ell} \) (the only ones to be generally non-degenerate). For those states, \( h = h_{1,s} \) and \( r = 0 \) or \( r = 1 \), so that we find from the formula (31) with \( c = -2 \),

\[
g\lambda_1 = \frac{g \pi^4}{N^3} \left( h_{1,s}^2 - \frac{1}{120} \right), \quad r = 0,
\]

\[
g\lambda_1 = \frac{g \pi^4}{N^3} \left( h_{1,s}^2 + 6h_{1,s} + \frac{119}{120} \right), \quad r = 1.
\]

The corrections obtained earlier in \( 7, 11 \) and \( 12 \) from the lattice transfer matrix are clearly reproduced by setting \( g = \lambda_3(c)/6r \). We note that \( c = -2 \) is the only value for which the perturbation theory correctly reproduces the lattice finite-size corrections. If we do not fix \( c \), we see from (10) that the weight \( h \) is shifted to \( h = h_{1,s} + \frac{c+2}{1440} \), and from the formula (31), the first order \( \lambda_1 \) for \( r = 0 \) and \( r = 1 \) gets an extra term, inside the parentheses, equal to \( \frac{(c+2)^2}{1440} \) and \( \frac{24(c+2)}{1440} \) respectively.
