ABSTRACT: A cobalt-catalyzed intermolecular three-component coupling of arenes, ethylene, and alkynes was developed using the well-defined air-stable cationic bis(phosphine) cobalt(1) complex, [(dicyclohexylphosphino)ethane]Co[(η⁶-C₆H₄)][BARF]₄, as the precatalyst. All three components were required for turnover and formation of ortho-homoallylated arene products. A range of directing groups including amide, ketone, and 2-pyridyl substituents on the arene promoted the reaction. The cobalt-catalyzed method exhibited broad functional group tolerance allowing for the late-stage functionalization of two drug molecules, fenofibrate and haloperidol. A series of control reactions, deuterium labeling studies, resting state analysis, as well as synthesis of substrate- and product-bound η⁶-arene complexes supported a pathway involving C(sp³)−H activation from a cobalt(III) metallacycle.

INTRODUCTION

Transition metal-catalyzed C(sp³)−H functionalization of arenes directed by commonly occurring functional groups such as amides and ketones has become established as a reliable approach to generate 1,2-substitution patterns in aromatic molecules. In particular, hydroarylation, the addition of a C−H bond across an unsaturated alkene or alkyne coupling partner, has been extensively investigated as an atom-efficient method for forming C−C bonds. While early developments in transition metal-catalyzed hydroarylation relied on the use of precious metals, recent emphasis has shifted to the development of Earth-abundant first-row transition metal catalysts. Cobalt-catalyzed directed C(sp³)−H functionalization has gained attention due to the tolerance of cobalt catalysts to a host of directing groups and coupling partners, often under mild conditions.

Central to the advancement of cobalt-catalyzed directed C(sp³)−H functionalization has been the development of well-defined precatalysts to promote the efficient generation of the active catalyst and to facilitate mechanistic insight. A pioneering example is the dicaticonic cobalt(III) complex reported by Matsunaga and Kanai in 2013, [(η⁶-C₆Me₆)Co(η⁶-C₆H₄)][PF₄]₄, originally reported for catalytic hydroarylation and subsequently applied to a wide array of ortho-C−H functionalization reactions. Reduced cobalt(0) and cobalt(−1) precatalysts have also been applied to C−H functionalization: Co(PMe₃)₄ by Petit in 2015 and [Co(PPh₃)₃(N₂)][Li(THF)]₄ by Tilley in 2020. Despite these advances, well-defined precatalysts for cobalt-catalyzed directed C−H functionalization remain few in number, and moreover, the aforementioned examples are not readily modified with different ligands, making the tuning of catalyst properties challenging. Consequently, the discovery of a modular cobalt precatalyst for directed C−H functionalization would facilitate the development and optimization of new catalytic transformations.

A. Well-defined cobalt precatalysts applied to directed C(αp)-H functionalization

B. C–H functionalization via a bicyclic metallacyclopentene intermediate (Cheng, 2014)

C. Challenge: Monocyclic metallacyclopentenes susceptible to unimolecular processes

D. This work: Three-component coupling of arenes, ethylene, and alkynes

Supported by analogy with organometallic and theoretical investigations on [2+2+2]-cycloadditions using isolated cyclopentadienyl-ligated cobalt(III) metallacyclopentadiene complexes. Despite the versatility of the metallacycle-mediated C–H functionalization in being compatible with a range of directing groups, this mode of C–H activation has only been demonstrated with 1,6-enyne substrates (n = 6, 7), limiting its application to selected classes of cyclized products. To expand the scope and synthetic utility of this type of transformation, intermolecular coupling of alkene and alkynyl components is desirable, resulting in a three-component intermolecular arene-alkene-alkyne coupling reaction to form ortho-homoallylated arene products.

Metallacyclopentenes, most commonly react by unimolecular pathways, including β-hydride elimination followed by C–H reductive elimination to form hydroyvinylation products, or direct C–C bond reductive elimination to form cyclobutenes (Scheme 1C). The selectivity of these product-forming processes is known to be highly dependent on the identity of the ligand bound to the cationic cobalt center. For example, cyclobutene formation is favored over β-hydride elimination when a wide bite angle bis(phosphine) such as dppe (1,2-bis(diphenylphosphino)propane) is used. Conversely, hydroyvinylation has been reported with dppe- and dppe-ligated cobalt catalysts (dppe = 1,2-bis(diphenylphosphino)propane; dppe = 1,2-bis(diphenylphosphino)ethane). Significantly, hydroarylation of the metallacyclopentene requires the intermediate to be sufficiently long-lived to promote a bimolecular C–H activation event. Compared with enyne substrates, which generate bicyclic metallacyclopentene intermediates by intramolecular oxidative cyclization, the intermolecular variant would form a potentially more reactive monocyclic metallacyclopentene. Unimolecular reactivity would be expected to be more facile from the monocyclic metallacycle, given that a bicyclic intermediate contains fewer accessible β-hydrogens, disfavoring hydroyvinylation, and would form a highly strained 4,5-bicycle upon C–C reductive elimination. Given the pronounced ligand effect on the reactivity of metallacyclopentenes, we envisioned a cationic cobalt(I) catalyst supported by a more strongly donating alkyl bis(phosphine) ligand could be developed to promote intermolecular three-component couplings by slowing the rate of unimolecular processes from the metallacycle.

Our group has reported the synthesis of a series of well-defined cobalt(0) and cationic cobalt(1) complexes bearing chiral bis(phosphine) ligands and demonstrated that both oxidation states are active precatalysts for asymmetric alkene hydrogenation. Similarly, (dppf)Co(COD) and (dicyclopenta-phenyl)phosphino)benzene] (COD = 1,5-cyclooctadiene) were prepared, and the cationic cobalt(I) variant was shown to catalyze olefin-alkyne [2+2]-cycloaddition. Here, we describe the synthesis and evaluation of a series of well-defined cationic bis(phosphine) cobalt(I) complexes as precatalysts for the intermolecular, three-component arene-alkene-alkyne coupling (Scheme 1D). The variant with an electron-rich alkyl bis(phosphine), [dicyclopenta-phenyl)phosphino)benzene] (1), was most effective and exhibited broad functional group compatibility, enabling the functionalization of marketed pharmaceutical compounds fenobistrate and haloperidol. Importantly, elucidation of the side-product profile, control reactions, and deuterium labeling experiments provided evidence for the intermediacy of a metallacyclopentene prior to C–H bond activation.

RESULTS AND DISCUSSION

Precatalyst Synthesis, Reaction Optimization, and Two-Component Control Reactions. A series of cationic cobalt(I) complexes were synthesized bearing dppf, dppe, dppbz (1,2-bis(diphenylphosphino)benzene), and dcype as representative bis(phosphines), and a labile naphthol ligand. Whereas the dppf-ligated complex [(dppf)Co(naphthol)] [BARF] (1), dppe, dppbz, and dcype-ligated variants were synthesized by analogy with our recently reported protocol using oxidatively induced reductive elimination from the corresponding cobalt(II) dialkyl derivatives.

To investigate the catalytic intermolecular arene-alkene-alkyne coupling, N-methylbenzamide (2a, 1 equiv), ethylene (5 equiv), and 6-dodecyne (1.2 equiv) were used as representative coupling partners, with 5 mol % of the cobalt precatalyst in THF and stirring at 40 °C for 24 h. Note that, as the alkylene was used in slight excess, the maximum theoretical yield of alkylene-derived products was 120%, accounting for the >100% overall yields reported in Table 1. With [(dicyclopenta-phenyl)phosphino)benzene] [BARF] as the precatalyst, the desired three-component coupling product 3aa was obtained in 30% yield (Table 1, entry 1). Notably, along with remaining starting material 2a, 3aa was the only benzamide-containing component.
observed in the reaction mixture, indicating a selective ortho-C–H functionalization had occurred with incorporation of one unit of ethylene and one unit of alkene in the product and with no difunctionalized product observed. The balance of the alkyl had predominantly been converted to cyclobutene 6 (73%), with hydrovinylation also being observed as a minor side product (5, 12%). While the observation of 5 as the major product is unsurprising, as cobalt complexes bearing dpf have previously been reported as efficient catalysts for [2+2]-cycloaddition, the observation of ortho-functionalized product 3aa motivated the exploration of other cationic bis(phosphine) cobalt(1) precatalysts.

With [(dppe)Co(η6-C5H5)][BARF4] and [(dpbbz)Co(η6-C5H5)][BARF4], the standard catalytic procedure produced trace 3aa (entries 2 and 3). The major products obtained from both precatalysts were higher molecular weight hydrocarbons arising from hydrovinylation and resulting from multiple additions of ethylene across 6-dodecylene. Conversely, employing [(dcype)Co(η6-C5H5)][BARF4] (1), which bears a more electron-rich alkyl-substituted bis(phosphine), produced a near-quantitative yield of 3aa, which was isolated in 96% yield after chromatographic separation (entry 4). Other products included a trace amount of difunctionalized product 4 and a small amount (15%) of hydrovinylation product 5. Increasing the amount of alkene to 2 equiv, 4 was obtained in higher (42%) yield, indicating that [(dcype)Co(η6-C5H5)][BARF4] was a sufficiently active precatalyst to mediate the second ortho-C–H functionalization (entry 5). The improved catalytic performance of the dcype derivative compared to other cobalt complexes supported by arylated bis(phosphine) ligands is consistent with the hypothesis of greater persistence of the dcype-ligated metallacyclopentene intermediate, which promotes intermolecular C–H activation of the arene substrate over unimolecular decomposition pathways.

Given the significant improvement observed with an alkyl-substituted bis(phosphine) ligand, other cobalt precatalysts bearing alkylated phosphines were evaluated in the three-component coupling reaction. Bench-stable, catonic cobalt(1) arene complexes have been synthesized for applications in asymmetric alkene hydrogenation, and with examples of DuPhos, BenzP, and TangPhos have been prepared. One example, [(τ5DuPhos)Co(η6-C5H5)][BARF4], proved to be a highly efficient and selective precatalyst for the three-component coupling giving 3aa and 4 in 90 and 10% yields, respectively (Table 1, entry 6). Both [(BenzP)Co(η6-C5H5)][BARF4] and [(TangPhos)Co(η6-C5H5)][BARF4] provided lower yields of 3aa (39% and 18%, respectively; entries 7 and 8), with the latter resulting in near exclusive hydrovinylation (5, 98%). The observation that all of the alkyl bis(phosphine)-ligated precatalysts studied gave appreciable yields of functionalized arene products highlights the greater activity and selectivity afforded by more electron-donating bis(phosphine) ligands in the three-component coupling. Although [(τ5DuPhos)Co(η6-C5H5)][BARF4] produced 3aa in high yield and selectivity, 1 was the preferred precatalyst due to the lower cost of the dcype ligand, and the transformation does not set a stereocenter. Because [(τ5DuPhos)Co(η6-C5H5)][BARF4] is a bench-stable alkene hydrogenation precatalyst, the air-stability of 1 was explored. A sample of 1 stored on the benchtop (in air, room temperature) for 7 days remained highly active, maintaining a near-quantitative yield of 3aa (entry 9).

Having optimized the conditions and precatalyst for the three-component coupling, the synthetic procedure to access [(dcype)Co(η6-C5H5)][BARF4] (1) was scaled to produce larger quantities of the cobalt arene complex (Scheme 2).

### Table 1. Reaction Optimization

| entry | L       | 3aa, % | 4, % | 5, % | 6, % |
|-------|---------|--------|------|------|------|

"Yields determined by 1H NMR spectroscopic analysis of the crude reaction mixtures against an internal standard. Combined theoretical yield of alkyne-derived products is 120%. Isolated yield. Two equiv of 6-dodecylene. Precatalyst 1 exposed to air for 7 days.

### Scheme 2. Gram-Scale Synthesis of [(dcype)Co(η6-C5H5)][BARF4], 1

Beginning from the cobalt(II) dialkyl precursor (py)Co(η6-(CH3SiMe3)2) coordination of the bis(phosphine) (7, 77%) followed by oxidation with FcBARF4 provided 1 as a yellow solid in 93% isolated yield. The procedure was routinely conducted to obtain gram-scale quantities of precatalyst 1. Both 7 and 1 were isolated by straightforward precipitation and filtration of the reaction mixtures.

To assess the intermediacy of a metallacyclopentene, two-component control reactions were conducted. Using 1 as the precatalyst, benzamide 2a was not functionalized in the
presence of either ethylene or 6-dodecyn alone (Scheme 3A). The lack of functionalized products suggests that C–H oxidative addition is unlikely to be the first mechanistic step of the three-component coupling, given that the putative Co–hydride (int-I) would be expected to mediate insertion of unsaturated coupling partners to form ethylated or alkynylated products. Furthermore, no reaction was observed when subjecting 2a to hydrovinylation product 5, indicating that 5 is not an intermediate in the formation of functionalized products 3aa or 4 (Scheme 3B). While attempts to isolate or directly observe a bis(phosphine)-ligated metallacyclopentene have thus far been unsuccessful, the results from these two-component reactions, in addition to side-product distributions observed in the reaction optimization and additional insight gained during the investigation of the reaction scope (vide infra), are most reasonably accounted for by a reaction pathway in which cobalt-mediated oxidative cyclization of the alkynyl and ethylene, forming a monocyclic metallacyclopentene (int-II), occurs prior to ortho-C–H functionalization of the arene (Scheme 3C).

**Scope of Arenes and Alkynes.** The scope of the three-component coupling was investigated with a range of arene and alkyn coupling partners. Using standard conditions, the reaction was generally effective with ethylene as the alkene component. Other alkynes such as propylene, styrene, and methyl acrylate were explored, but no reaction was observed in each case. Both cyclic and strained alkynes such as cyclopentene or norbornadiene were unsuccessful as coupling partners in the reaction.

The scope of directing groups on the arene was first examined (Scheme 4). Secondary amides with N-alkyl and N-phenyl substituents, as well as primary and tertiary amides, gave excellent yields of the three-component coupling products (3ab, 3b–d, 92–97%), while a bicyclic secondary amide substrate gave a moderate yield (3e, 43%). Notably, product 3ab was synthesized on a gram-scale with a lower precatalyst loading of 1 mol % (1.3 g of 3ab). Interestingly, the more strongly donating pyridine directing group was inferior and produced 3f in 29% yield, whereas other carbonyl-containing directing groups such as ketones and aldehydes afforded high yields of functionalized products when using modified conditions with the arene being used in excess (3g–i, 71–88%). Ester and anilide directing groups were also evaluated but provided low yields, presumably due to weak coordination of the carbonyl in the former case and the carbonyl group being more distant relative to the ortho-C(sp²)–H bond in the latter.

The functional group compatibility in the arene component was also explored (Scheme 5). Electron-donating and -withdrawing substituents were effectively tolerated in the reaction (3j–n, 51–95%), including functional handles such as halides and a boronate ester. For 3-substituted arenes, ortho-functionalization occurred at the least sterically hindered position, with the 3-methoxy substitution giving a 89:11 mixture of 1,2,5- and 1,2,3-substituted products (3j). In the case of a 3-chloro substituent, exclusive formation of 1,2,3-substituted product 3k was observed. For substrate 2n, which contains both ketone and ester functional groups, functionalization was only observed ortho to the ketone (3n). Significantly, the catalyst also efficiently mediated alkynyl C(sp²)–H functionalization, with the isolated product having (Z)-alkene stereochemistry of the acrylamide, as expected from amide-directed C–H bond activation (3o, 93%). Various heterocycles were suitable substrates for the three-component coupling, including pyridine, indole, and thiophene (3p–r, 58–91%). Furthermore, marketed pharmaceutical drugs, fenofibrate and haloperidol, provided good yields in the reaction (respectively, 3s, 91% and 3t, 54%). For fenofibrate, the 4,4′-substitution of the benzophenone gives rise to an
intramolecular competition of 4-chloro- and 4-alkoxy-substituted ring systems, and the cobalt-catalyzed method provided a 63:37 ratio of isomers. The major isomer resulted from C−H functionalization of the more electron-rich alkoxy-substituted ring.

Finally, the scope of the alkyne coupling partners was explored (Scheme 6). Changing from a dialkyl alkyne coupling partner to diphenylacetylene, the three-component coupling product was obtained in good yield (3ac, 72%). The ortho-functionalized arene was unambiguously characterized by single-crystal X-ray diffraction, confirming the trisubstituted alkene (Z)-stereochemistry. In all examples examined, only syn-addition across the alkyne component was observed in the isolated products, and thus positional or stereochemical isomerization of the product alkene did not occur under catalytic conditions. Dimethyl acetylenedicarboxylate also proved to be a competent symmetrical alkyne coupling partner, affording the desired product in high yield (3ad, 90%). Unsymmetrical alkynes were next explored in the reaction. It is important to note that two potential regioisomers of the product are possible depending on which carbon atom of the alkyne the C−C and C−H bonds form with en route to possible metallacyclopentenes that could be obtained from oxidative cyclization of the alkyne with ethylene (int-IIIa or int-IIIb). Employing 1-phenyl-1-propyne, the functionalized product was formed in high yield and regioisomeric purity (3ae, 97%, 11:1 r.r.). Analysis by NMR spectroscopy identified the major isomer as having the phenyl substituent at the terminal alkene position and the methyl group at the internal

position. To examine the effect of steric on the regioselectivity of the reaction, a series of alkenes containing a methyl substituent and alkyl substituent of increasing size (ethyl, iso-propyl, tert-butyl) were used. Ethyl and iso-propyl substituted alkenes gave high yields of three-component coupling products (3a-f, 87–98%), whereas the tert-butyl group resulted in noticeably decreased conversion (3ah, 15%). In each case, the major regiosomer had the smaller methyl substituent at the terminal alkene position. Notably, this contrasts to the reaction using 1-phenyl-1-propyne which favored the larger phenyl group being placed at the terminus of the product. Increasing the size of the alkyl substituent from ethyl to iso-propyl to tert-butyl increased the regioselectivity from 1:4:1 to 7:1 to >20:1 r.r., likely reflecting the increasing steric clash between the catalyst and alkene substituent upon metallacycle formation when the larger substituent is proximal to the metal center (Scheme 7B). Lastly, in terms of functional group tolerance in the alkene component, alkenes containing pendant hydroxyl, thioether, and protected amine groups performed well in the reaction (3ai-k, 66–90%).

In general, the three-component coupling selectively generated mono-ortho-functionalized products, with di-ortho-functionalization obtained as a minor product in some instances. During the exploration of the alkene scope, it was found that using ethyl 2-pentynoate resulted in a mixture of two mono-ortho-functionalized products (Scheme 8A). The major product was the expected three-component coupling product derived from the arene, ethylene, and alkene, which was formed in high regioselectivity with the ester group at the terminal alkene position in the product (3a, 64%, >20:1 r.r.). The minor product was derived from the arene and 2 equiv of the alkene without incorporation of ethylene, resulting in an ortho-functionalized product containing a 1,3-diene moiety (8, 27%). Significantly, the two-component reaction in the absence of ethylene afforded 8 as the sole functionalized product in 43% yield. Given that the hydroarylation products resulting from insertion of only 1 equiv of alkene, or from insertion of more than 2 equiv, were not observed corroborates with the intermediacy of a metallacyclopentadiene7a,b,9 formed from the oxidative cyclization of the cobalt catalyst with 2 equiv of ethyl 2-pentynoate. In the presence of ethylene, the formation of both 3a and 8 indicates that the formation of metallacyclopentene int-IV and metallacyclopentadiene int-V are competitive under the reaction conditions.

The formation of diene-containing arene products was not observed in other three-component coupling reactions conducted with internal alkynes. Conversely, the use of phenylacetylene, a terminal alkynie coupling partner, resulted in exclusive formation of the diene product derived from the arene and 2 equiv of alkene (9, Scheme 8B). In both the presence or absence of ethylene, diene 9 was formed as the sole product, albeit in moderate yields (30% and 29% yield, respectively), indicating that metallacyclopentadiene formation is facile compared with metallacyclopentene formation.

**Deuterium Labeling Studies.** To gain additional insight into the reaction mechanism, deuterium labeling studies were conducted. Using N-methylbenzamide-d5 (2a-d5, >99% D in ring positions), ethylene, and 6-dodecene as coupling partners, the d5-labeled three-component coupling product (3aa-(sp2) d5) was obtained in >98% assay yield (Scheme 9A). While the ortho-deuterium atom in 2a-d5 was predominantly transferred to the alkynie position in product 3aa-(sp2) d5, a small but significant deviation from complete transfer was observed (88% D at the alkynie position in 3aa-(sp2) d5). In addition, H/D exchange occurred to a minor extent at the unfunctionalized ortho position in 3aa-(sp2) d5 (97% D), whereas the other remaining ring positions remained fully labeled (>99% D). Analysis of the unpurified reaction mixture from the three-component coupling by NMR spectroscopy revealed that loss of deuterium in 3aa-(sp2) d5 was traced to the hydrovinylation side product, which was substantially deuterated at the alkynie position of the trisubstituted alkene (5-d5, 76% D). More specifically, the amount of deuterium incorporated in 5-d5 (0.17 × 76% = 13% D) correlated with the amount of deuterium lost at the alkynie and ortho-aryl positions in 3aa-(sp2) d5 (12% + 3% = 15% H), indicating that the extent of hydrovinylation was related to the observed H/D exchange.27

Possible pathways to account for the outcome of the cobalt-catalyzed three-component coupling using deuterated arene are presented in Scheme 9B. First, β-hydride elimination directly from the metallacyclopentene (int-VI) and C=H reductive elimination liberates the natural abundance hydrovinylation product 5. Alternatively, the metallacyclopentene int-VI may promote C=O bond activation, where the ortho-deuterium atom is transferred to the sp2-carbon of the metallacycle. The resulting cobalt(III) intermediate (int-VII) may undergo either product-forming C–C bond reductive elimination, forming 3aa-(sp2) d5, or alternatively, the Co-alkyl

Reactions were carried out on a 0.5 mmol scale; r.r. determined after purification by 1H NMR spectroscopy.
could undergo β-hydride elimination and C−H bond reductive elimination to yield \( d_1 \)-labeled hydrovinylation product 5-\( d_1 \), along with 2a-\( d_4 \) in which ortho-D-for-H exchange has taken place. If 2a-\( d_4 \) re-engages the metallacyclopentene to promote ortho-functionalization, an intermolecular competition between C−H and C−D activation would then occur. The preference for ortho-C−H over \( C−D \) activation within 2a-\( d_4 \) accounts for the greater loss of deuterium at the alkenyl position relative to the unfunctionalized ortho-position observed in the isolated three-component coupling product (88% D compared to 97% D). Based on this proposal, the relative amount of 5-\( d_1 \) compared to the three-component coupling product formed in the reaction reflects the efficiency of the catalyst to promote product-forming reductive elimination over β-hydride elimination from the putative cobalt(III) intermediate int-VII.

In the context of the proposed mechanism, the three-component coupling using ethylene-\( d_4 \) with natural abundance 2a and 6-dodecyne was conducted (Scheme 9C). As expected, functionalized product 3aa-(\( sp^3 \))-\( d_4 \) was formed in high yield with fully deuterated carbon atoms within the linking ethylene unit (>99% D). Small but detectable amounts of deuterium were also incorporated at the ortho-to-amide and alkenyl positions in 3aa-(\( sp^3 \))-\( d_4 \) (8 and 2% D, respectively), which correlated with the yield of \( d_1 \)-labeled hydrovinylation product 5-\( d_1 \) (10%). The observation of 5-\( d_1 \) is consistent with H/D-exchange between ethylene and arene during the three-component coupling. Interestingly, \( d_4 \)-labeled 5 was not detected, indicating that 5 was no longer formed directly from the metallacyclopentene and is attributed to slower β-D elimination from this metallacyclic intermediate.

Parallel reactions using 2a or 2a-\( d_5 \) with ethylene and 4-octyne were conducted to measure the deuterium kinetic isotope effect for the catalytic reaction by measuring the initial rate of formation of the three-component coupling product (5−25% yield). A \( k_{H}/k_D \) value of 1.1(3) was obtained at 30 °C, suggesting that C−H activation does not occur during the turnover-limiting step (Scheme 10A). Recognizing that ortho-D-for-H exchange within the substrate likely occurs over the course of the reaction with the deuterated substrate, chromatographic separation of the remaining starting material 2a-\( d_5 \) and product 3ab-\( d_5 \) at the final time point from the initial rate experiments was carried out. Compared with the isolated material of 3aa-(\( sp^3 \))-\( d_4 \) from the reaction that was run to completion (Scheme 9A), minimal loss of deuterium was...
observed for both recovered 2a-d₅ (98% D across two *ortho* carbons) as well as the isolated product 3ab-d₅ (95% D at the alkenyl position and 99% D at the *ortho*-position). The greater deuterium incorporation observed at partial conversion not only validates the measured KIE from the parallel experiments but also provides additional support for the proposed mechanism which suggests that *ortho*-D-for-H exchange would be more substantial at later time points of the reaction. Finally, an intermolecular competition KIE for 2a and 2a-d₅ was also measured (Scheme 10B). A KIE of 3.0 was obtained at 30 °C, consistent with irreversible C−H activation that occurs following the rate-limiting step.

**Resting State Analysis.** The resting state of the catalytic three-component coupling reaction employing N-methylbenzamide, ethylene, and 4-octyne, with [[(dcype)Co(η⁶-C₇H₈)]][BArF₄] as the precatalyst, was monitored by ³¹P NMR spectroscopy in THF-d₈ (Scheme 11A). Three phosphorus signals were observed during the reaction, one of which was identified as the precatalyst, [[(dcype)Co(η⁶-C₇H₈)]][BArF₄] (δ = 95.8 ppm). Independent synthesis of the substrate- and product-bound η⁶-arene complexes (10 and 11) confirmed the identity of the two other signals (δ = 94.6 and 92.8 ppm, respectively; Scheme 11B), and the solid-state structure of 10 was determined by X-ray diffraction (Figure 1). The toluene-bound complex 1 was observed throughout the reaction indicating that toluene binds more strongly to the cobalt center compared to the substrate or product benzamides. No other cobalt complexes other than η⁶-arene complexes were detected by ³¹P NMR spectroscopy. Having identified the catalyst resting states, coupled with the observation that C−H activation is not part of the turnover limiting step of the catalytic cycle, either displacement of the η⁶-ligated arene by alkyne and ethylene or the subsequent [2+2]-oxidative cyclization to form the metallacyclopentene is likely the slow step in the reaction.

■ **CONCLUSIONS**

A three-component arene-ethylene-alkyne coupling reaction has been developed using a cationic dcype-ligated cobalt(I) arene precatalyst. The reaction was effective with a range of arene and alkynecoupling partners, producing a broad array of functionally diverse *ortho*-homosallylated arene products. Deuterium labeling studies and KIE determination for the three-component coupling reaction found that C−H activation occurs irreversibly but is not part of the turnover-limiting step of the catalytic cycle. Resting state analysis identified that the
catalytic resting state is distributed among a series of $\eta^6$-arene cobalt(1) complexes, including the toluene-bound precatalyst and substrate- and product-bound $\eta^6$-arene complexes. Two-component control reactions using an arene partner with a dialkyl alkynyl or ethylene did not result in the generation of ortho-functionalized products. Conversely, two-component reactions employing an alkynyl with an ester and an alkyl ortho-dialkyl alkynyl or ethylene did not result in the generation of component control reactions using an arene partner with an alkyl substituent, or use of a terminal alkynyl, led to the selective formation of ortho-functionalized 1,3-diene-containing products derived from the arene and 2 equiv of the alkynyl. Taken together, the results of the two-component reactions suggest that cationic bis(phosphine) cobalt complexes promote $C\equiv H$ functionalization through a pathway involving oxidative $[2+2]$-cyclization followed by $C\equiv H$ activation en route to the ortho-functionalized products. In the case of the three-component coupling, a metallacyclopentene intermediate is formed by oxidative $[2+2]$-cyclization of an alkynyl and ethylene, whereas formation of a functionalized product incorporating two units of the alkynyl may occur via a metallacyclopentadiene generated by $[2+2]$-cyclization of 2 equiv of the alkynyl. Overall, the discovery of a readily prepared bis(phosphine)-ligated cobalt precatalyst capable of promoting metalacycle-mediated $C\equiv H$ activation by intermolecular alkynyl-alkyne oxidative cyclization opens new opportunities in metal-catalyzed $C(sp^3)\equiv H$ functionalization, and such applications are currently under investigation.
