Abstract

Background

Assistive Technology (AT) supports persons with dementia and their carers (family, friends and neighbours), yet little is known about experiences and the impact of AT on carers. We report on an exploratory survey that examined the types, uses, costs and impact of AT on carers as well as their quality of life.

Methods

A cross-sectional survey using the Carers Assistive Technology Experience Questionnaire collected data from carers in the UK, who used at least one AT in the previous year and provided more than 10 hours of care for a person with dementia, living at home. Carers completed the questionnaire online or on paper and information on AT, socio-demographic details, and Short-Form Health Survey (SF-12) data were collected. Descriptive and inferential statistics were used to report results and draw conclusions.

Results

Data from 201 carers was analysed. Smartphones and tablet computers were the most frequently used AT. AT were used predominantly for safety, communication, and reminders. Carers usually make decisions on buying and continued use of AT. Multiple AT devices were used in the care of persons with dementia and number of AT used was associated with perceived satisfaction. Satisfaction with AT was not related to age, living arrangements and relationship of carers. From the SF-12, Mean Physical Component Score was 49.19 (95%CI- 47.75 to 50.63) and Mental Component Score was 45.37 (95%CI- 43.93 to 46.80). Women, carers in the 46-65 age group and carers who were not extremely satisfied with AT had lower MCS scores. Carers who lived with the person with dementia and older carers had lower PCS scores.

Conclusions

Carers report that AT has a beneficial impact. Carers use multiple ATs, perceive AT to be satisfactory and recommend AT use to others. To support carers, we recommend establishment of centrally funded information sources and a loan store for AT. Further research on incremental addition of AT and changes to formal/paid care because of using AT should be undertaken. Practitioners, academics, manufactures and policy makers should consider the experiences of carers in research, development and use of AT to facilitate improved community living of people with dementia.

Background

Dementia is a progressive disorder and a public health priority[1, 2]. Some estimates suggest a worldwide societal cost of dementia at approximately US$1 trillion, with this cost doubling by 2030 [3]. A vast amount of the care for persons with dementia who live at home is provided by informal carers (family, friends and/or neighbours) [4, 5]. Within the UK approximately 700,000 informal carers (hereafter referred to as carers) support persons with dementia [5]. With an aging population, this demand for time and support from carers is likely to grow [6]. Assistive technology (AT) could support people with dementia and their carers within the community [7–9]. AT can be defined as: “any item, piece of equipment, product or system that is used to increase, maintain or improve the functional capabilities and independence of people with cognitive, physical or communication difficulties” [10]. In spite of technology being viewed as a pervasive solution to supporting carers and persons with dementia to live for longer in the community [11–13] there have been very few attempts to understand the experiences of carers, who use and support the use of AT; and their perceptions of the impact of these ATs [9, 14]. Additionally, there continues to be a lack of understanding of the number of AT available and their uses; the ethical implications of choice and continued use of certain AT for privacy and confidentiality; and the perceived satisfaction with and benefits of use of AT from the perspective of the carers [15]. To provide a broader understanding of the experiences of carers using or supporting a person with dementia to use AT, this survey aims to understand the current use, satisfaction and impact of AT among carers of persons with dementia. Information was gathered using the Carers Assistive Technology Experience Questionnaire (CATEQ) [9, 15, 16].

Study objectives:

This study investigated the following questions:

1. The types and use of AT by carers in the support of persons with dementia.
2. Identify outlay costs, monthly on-going costs and perceived value for money of AT.
3. Perceived impact of AT for carers in dementia care.
4. General physical and mental health of carers of persons with dementia who use AT.

Ethics and Patient and Public Involvement:

This study was approved by the University of Oxford Central University Research Ethics Committee (Reference number: R57703/RE002). No personal identifiable information of participants is reported in this paper. This study is part of a larger research project which has a patient and public advisory group that meets twice a year. This group consists of two carers of persons with dementia and a person with dementia (all living in England). This group reviewed the final version of CATEQ submitted for ethical approval. This group has also committed to support dissemination of study results to other patient involvement groups and their wider networks.

Methods
Study Design:

We conducted a cross-sectional survey between April to July 2020, using the CATEQ. Data was collected by giving potential participants the option of completing the questionnaire electronically through an anonymous link using the electronic survey platform Qualtrics [3] or by post with the printed questionnaire mailed to participants who requested it, with a pre-paid return envelope. A consent question was included at the start of the questionnaire and informed consent was required for online respondents to continue with the survey. Postal versions included the consent question as part of the paper questionnaire and, in addition, participants were instructed to not send back the questionnaire if they did not consent to participating in the survey. We have used STROBE cross sectional reporting guidelines to structure the manuscript [17].

Participants:

Participants were recruited using online databases via the Join Dementia Research website [18] and Oxford Dementia and Aging Research (OxDARE) [19] and to increase participation from carers from different ethnic backgrounds, requests were made through health care professionals who prescribe AT for persons with dementia. Participants were carers of persons with dementia based in the United Kingdom. The inclusion criteria were: adult carers - family, friends or neighbours - providing at least 10 hours of care (e.g. shopping, leisure, personal care, finance) per week to a person with dementia who lives in their own home, with the carer living together with or away from the person with dementia; carers needed to have used at least one AT device at home in the previous year and be able to complete the questionnaire in English.

Questionnaire:

Carers Assistive Technology Experience Questionnaire (CATEQ):

The development of the questionnaire is described elsewhere [manuscript under consideration], briefly it involved developing items for the questionnaire based on a systematic review [9] and qualitative study [15], designing and conducting cognitive interviews to test items of the questionnaire; iterative revision of questionnaire based on the cognitive interviews; and final testing on volunteers of the patient and public advisory group. The questionnaire contains questions on types and uses of AT, support provided by the AT, impact of using AT and questions to collect socio-demographic information; with free-text spaces for respondents to qualify their answers if necessary. The time needed to complete the questionnaire was less than 30 minutes. The full questionnaire is available [supplementary file 1].

SF-12:

The survey also included the SF-12 Health Survey (version1) [20–22]. The SF-12 contains items covering physical functioning, social functioning, role functioning (physical and mental), vitality, bodily pain, mental health and general health. The SF-12 generates two summary scores: The Physical Component Score and the Mental Component Score (PCS and MCS respectively). The PCS and MCS are generated using norm-based methods and are standardised, using scores from the general population[20, 23], to have a mean of 50 (SD 10). A higher score indicates better quality of life.

Independent variables:

Carer socio-demographic variables were collected to describe participants. These included age, sex, employment status, marital status, ethnicity, education level, annual family income, living arrangements and relationship with the person with dementia.

Dependent variables:

For objective (1) - The types and use of AT by carers in the support of persons with dementia - the types and uses of the AT were explored using a list of AT as well as open ended questions asking participants to record AT not listed. For objective (2) - Identify outlay costs, monthly on-going costs and perceived value for money of AT - participants were asked to provide approximate expenditure in Great British Pounds for the initial purchase and monthly ongoing costs of using the AT, as well as indicating who paid for the AT. For objective (3) - Perceived impact of AT for carers of persons with dementia - carers indicated perceived impact of AT in reducing harm, additional time for carers, reducing stress and managing anxiety, concerns about privacy and confidentiality, how AT meets their needs and overall satisfaction with AT. For objective (4) General physical and mental health of carers of persons with dementia who use AT - quality of life of carers who participated was explored with data from the SF-12 in addition to questions on impact of caring on coping and their health.

Statistical Methods:

Data analyses were carried out using IBM SPSS Statistics version 26. Descriptive statistics in the form of frequency distributions, percentages, means, standard deviations, and medians were used to examine the types of AT used, what the AT was used for, costs of the AT, perceived value for money and satisfaction with the AT. Bivariate analyses involving a chi-square test, a Mann-Whitney U test and a Kruskal-Wallis test were conducted to examine differences in socio-demographic variables such as education level, living arrangements and relationship status between respondents and SF-12 MCS and PCS scores. An independent-Samples Kruskal-Wallis Test was used to analyse perceived value for money and total costs and monthly costs of use of AT. The level of significance was set at p<0.05 for all analyses.

Results:

A total of 215 questionnaires were returned by respondents. Sixty-six completed questionnaires were returned from a total of 85 participants who requested for the postal questionnaire. A further 149 questionnaires were returned using the online anonymous link on the Qualtrics survey platform. Of these, 3
respondents declined to give consent at the start of the online questionnaire and did not proceed further and were excluded. A further 11 respondents had not completed the questionnaire further than listing the AT used and so their data were excluded. This left a total of 201 participants after exclusions.

Description of participants:

There were 131 (65.2%) women and 65 men (32.3%) with 1 participant self-identifying as non-binary and 4 missing values. Participants’ age ranged from 33 to 92 with a mean age of 62 (SD 12) with most participants between 46-65 years (n=105; 52.2%) followed by participants between 66-85 years (n=74; 36.8%). Participants were predominantly white (n=186; 92.5%), currently married (n=158; 78.6%) and with a university degree (n=127; 63.2%). Participants were children of a person with dementia (n=110; 54.7%) or a spouse of a person with dementia (n=72; 35.8%) with others caring for in-laws, uncles, and stepparents. For those willing to disclose annual family income (n=153; 76.1%), most participants earned between £10,000 - £40,000 (n=86; 42.7%). A fuller description of the participants is available in Table 1.

Types and uses of AT:

Participants reported using a wide variety of AT (Table 2). Frequently used AT were smart phones (n=91; 45.5%) and tablet computers (n=90; 45.0%) followed by video communication systems (n=89; 44.5%) and dementia clocks (n=82; 41.0%). Less frequently used AT included stair lifts, electric toothbrushes, and hoists. Carers used between 1 to 13 different ATs, with 37.8% carers using less than 4 ATs and 62.2% carers using 5 or more ATs. There was no difference in numbers of AT used or abandoned to the age of the carer. AT were predominantly used for safety (n=157; 78.5%) and communication (n=132; 66.0%), followed by AT used to support memory and provide reminders (n=125; 62.5%). AT were least used for managing everyday spending (n=8; 4.0%) and for activities of daily living such as supporting eating, washing etc. (n=17; 8.5%). Among those participants (n=88) who stated that some AT devices that were no longer in use, pendant alarms (n=35; 41.2%) and audio books (n=22; 25.9%) were the most frequently abandoned AT devices. The main reason why AT were abandoned were reported to be because the person with dementia was no longer able to use them (n=69; 81.2%).

Costs of AT:

Carers chose AT predominantly by themselves (43%), followed by carers choosing along with the person with dementia (21%) and then by health or social care professionals choosing the AT (18.9%). Only 7 participants reported that the AT was chosen exclusively by the person with dementia. From participants who reported (n=168), initial costs for the AT ranged from £16.00 to £10,000 (median = £400) and monthly ongoing costs (n= 179) ranged from no additional costs to £150.00 a month (median = £17). The monthly costs usually involved expenditure towards pendant alarm subscriptions and monthly phone subscription and internet costs. The AT was purchased predominantly by the participant (54.4%), by another carer (10%), by the person with dementia (23.9%); or provided by social services/health system without a charge (9.7%). Most of the carers rated the AT they were using were either extremely good (35.3%) or somewhat good (49.3%) for value for money. Carers would definitely (62.7%) or probably (31.3%) recommend the use of AT to other carers, with no carers saying they would not recommend AT. There was no significant difference in the initial and monthly costs of AT to the perception of value for money (Table 3).

Perceived impact of AT:

Carers were asked to choose up to three currently used AT and asked to respond to questions on how the nominated AT helps reduce their effort in caring for someone with dementia, their perceived impact of AT in reducing stress, managing anxiety, reducing harm/potential harm to the person with dementia and making their caring role easier (Table 4). Carers indicated that the level of care provided to the person with dementia had not changed (48.3%) since the introduction of AT; with some carers reporting that AT improved a little (32.6%) and improved a lot (11.5%) of the care provided. Carers (n=123) felt that AT was very helpful (24.9%) or helpful (21.1%) in reducing the need for additional paid care. 34.8% of carers reported being extremely satisfied with the AT, with carers using 5 or more AT devices being significantly more satisfied with AT than carers using 4 or less AT devices (p=0.001). There were no significant differences between level of satisfaction with AT to age, living arrangements or relationship with the person with dementia.

General physical and mental health of carers:

Mean PCS and MCS scores were calculated for the SF-12 (Table 5). The mean PCS (n=201) was 49.19 (95% CI 47.75 – 50.63) and the mean MCS (n=201) was 45.37 (95% CI 43.93 – 46.80). PCS scores were significantly (p<0.001) associated with age, with older carers having lower PCS scores. MCS scores were also significantly associated with age (p= 0.012) with carers in the 46-65 age group having lower MCS scores than other age groups and women having lower MCS scores compared to men (p=0.002). Carers who lived with the person with dementia had significantly (p=0.001) lower PCS scores than those who lived away. Children had better PCS scores than spouses (p<0.001). MCS scores were significantly higher (p=0.010) in carers who expressed they were extremely satisfied with the AT but there were no significant differences in PCS and MCS scores to the number of AT used. There was no significant difference between the number of AT being used to the perceived impact on caring, coping, and personal relationship with the person with dementia. There was a significant relationship between coping with caring (p<0.001) and perceived relationship (p=0.003) with the person with dementia with those who coped well and had a good relationship with the person with dementia having better PCS and MCS scores.

Discussion

This study adds to the literature on carers’ experiences of using AT and examines its impact on a sample of carers across the UK. We found carers and persons with dementia use a wide variety and multiple types of AT devices. Smart phones and tablet computers were predominantly used, this is perhaps because they can be used for more than one purpose, such as communication, safety (tracking, medication reminders) and leisure activities. The use of AT largely for safety (monitoring/tracking, movement sensors, pendant alarms, medication management), followed by communication and reminders is similar to earlier findings [24]. We found that age is not a barrier to the number of AT being used, or a reason for abandoning AT, which is dissimilar to previous findings
This study also provides information on the range of expenditure on AT currently being used in dementia care. Carers consider AT as good value for money, due to the perception of AT supporting safety and communication (useful for both the carer and the person with dementia) and leisure of the person with dementia. This could support the person with dementia living for longer at home [27]. Carers decide and are willing to abandon AT especially devices such as pendant alarms when it is no longer possible for the person with dementia to use them. This continues to raise the issue of the suitability of AT that are purchased, trialled, and then abandoned - increasing waste both economically for carers and environmentally. To avoid this, focus of care for a person with dementia should be seen as a long-term condition, with an unpredictable progression. Health care providers, carers and persons with dementia would benefit from a centrally-funded access point to high-quality information on AT (this is currently only being provided by charities/third sector organisations) and establishing local loan stores for AT [15]. Interestingly ethical reasons are not highlighted as a prime reason for abandoning AT, this could be because carers feel the overriding reasons of safety and welfare of the person with dementia is more important [12, 28].

Caring could be a positive experience for some but it does have an influence on anxiety, stress and fatigue, as well as causing problems with physical health among family carers [29]. None of the carers in our study, felt they could not recommend the AT to other carers; this could be because carers, irrespective of perceived impact and personal satisfaction with the AT, feel AT enhances and/or supplements care for a person with dementia and their own quality of life. In this survey, carers report that AT had an impact on caring. We found, carers felt no change in the effort of caring since they started using AT, this could be because the progress of dementia is often slow and unpredictable, and perhaps AT is helping to maintain the status quo of the needs of a person with dementia; in addition, the care could also be supplemented by support from formal carers. Carers felt that AT helps in reducing their stress and anxiety, this could be because AT devices for communication and safety provides a sense of reassurance for carers, especially when they live away from the person with dementia. Carers did not perceive AT as being useful in reducing harm, this may be because AT such as smart phones and tablet computers are seen as devices that facilitate communication and leisure, rather than safety and welfare. Carers also felt that AT helped reduce the need for additional paid care, whilst our study did not quantify this, it should be an area for further investigation into the economic advantages of using AT. This study also reveals that, larger the number of AT being used the greater the satisfaction with AT. While this needs to be further explored, one reason could be because carers may be sequentially adding AT, i.e. using additional AT one at a time, based on the changing needs of the person with dementia and hence could be more satisfied when the additional AT meets their needs.

Carer-person with dementia relationship, carer physical and emotional well-being and coping with the demands of caring are all dimensions of quality of life of family carers [30–32]. This survey provides an insight into the quality of life of carers who are currently using AT. Older carers had lower PCS scores similar to other studies [3, 33], this could also explain why spousal carers had lower PCS scores, than children who care for persons with dementia. MCS scores for carers in the 46-65 age group was significantly lower, this could be because carers within this age group are likely to be the “sandwich” generation [29], with responsibilities for caring for their own children and families whilst having to care for their aged parents. Previous research [9, 34, 35] has shown that there were fewer number of AT that met the needs of basic activities of daily living such as eating and bathing etc., which is confirmed by our survey. Basic activities of daily living, could be the tasks that a person with dementia is most dependent on [35] and carers living with persons with dementia are likely to be spousal carers and living with the person with dementia would mean carers being called on to physically assist them more often, this could explain why PCS scores were lower for carers living with the person with dementia. It has been reported earlier [36, 37] that coping with care responsibilities and actual relationship with the person with dementia has a direct effect on carer quality of life, this is confirmed in our survey. AT helps carers manage their stress and anxiety as well as making their caring role easier, this could explain why those carers who felt extremely satisfied with the AT had better MCS scores and the reason for using the AT for reassurance (safety, communication) might be more important for carer quality of life. The amount of informal care provided to older people with disabilities in England is unlikely to keep pace with demand [6], this disconnect has been sharply highlighted in restrictions and increased reliance on technology brought about by the covid-19 lockdown [38–40]. For dementia care, as this study shows, AT may help bridge this gap by reducing the need for physical contact based informal care or by improving the efficiency of this care. This could be why carers who felt that their relationship and ability to cope with caring for a person with dementia had better PCS and MCS scores.

Implications for practice, policy and research:

Increasing amount of care for persons with dementia is being provided by carers. AT manufacturers and healthcare professionals advocate AT as a solution to decrease the amount of formal care and care provided in residential settings. This raises important issues in long-term dementia care. Assessment and use of AT by carers of persons with dementia, should consider dementia as a long-term condition and move away from applying the existing ‘acute care’ model of brief interventions and rigid protocols (such as providing pendant alarms to all persons at risk of falls) to a fundamentally unpredictable condition[41]. AT providers and healthcare professionals could use a survey tool such as the CATEQ periodically to sense check the types, uses and impact of AT and modify development of new AT and provision of AT to people with dementia. Policymakers should undertake a concerted effort to provide a centrally funded access point to high-quality information on AT and consider set-up and expanding use of a loan store for AT devices for dementia. Policies should be formulated to support research and Government backing to provide focused funding that can capitalise on emerging artificial intelligence driven technology that are incorporated into smart phones and tablet computers, that could provide further support for carers and persons with dementia. Further research is needed to find what if any influence the incremental addition of AT can have on satisfaction and impact on carer quality of life and the need for additional formal/paid care. Better integration of various types of AT into fewer AT devices and cost-benefit analysis of AT use in reducing the need for formal/paid care or longer community living should also be explored.

Strength and Limitations:
This study provides insight into the current use and impact of AT in dementia care across the UK. This questionnaire covered items related to uses, costs, impact and satisfaction giving a much better understanding of carers' experience with AT. One of the limitations for this study is that the questionnaire was in English and despite intensive efforts, we could not increase participation from carers from a non-white ethnic background. This has meant our sample may not fully represent the multicultural UK population. This survey was launched just before the lockdown and subsequent restrictions due to Covid-19 in the UK, which could have resulted in inability of some carers to respond to the survey, for e.g. not able to go out due to shielding, to post paper questionnaires or increased caring responsibilities due to reduced services or other support. This could have led to fewer responses from carers who are using AT to look after the most vulnerable of persons with dementia.

Conclusion

This study provides information on carers' experiences with using AT in dementia care. Safety, memory, and communication are areas where AT are most used. Our study finds that AT can support carers in their efforts in caring for someone with dementia. Carers report that AT helps them in reducing effort, making the caring role easier and reducing stress. However, additional support is needed for carers in the choice, purchase and continued use of AT. Incremental use of AT and cost-effectiveness of AT in supporting the person with dementia and their carers are areas where future service development and research should target. Viewing dementia as a long-term condition with planned use of AT as a solution in the care pathway could offer a positive experience of dementia care at home.

Declarations

Ethics approval and consent to participate:

This study was granted ethical approval by the University of Oxford Central University Research Ethics Committee (Reference number: R57703/RE002). Participant consent was included at the start of the questionnaire and informed consent was required for respondents to continue with the online survey. Postal versions included the consent question as part of the paper questionnaire and, in addition, participants were instructed to not send back the questionnaire if they did not consent to participating in the survey.

Consent to publish:

Not required

Availability of data and materials:

The datasets generated during the study are available from the corresponding author on reasonable request.

Competing interests:

The authors declare that they do not have any competing interests.

Questionnaire:

The Carers Assistive Technology Experience Questionnaire (CATEQ) was developed by the authors based on earlier research carried out by the authors and did not require a licence for use in this survey. The SF-12 survey version 1 is available in the public domain and does not require a licence for non-commercial use.

Funding:

This research is part of a DPhil in Population Health at the University of Oxford and received no specific grant from any funding agency in the public, commercial or not-for-profit sectors.

Authors' contributions:

VS, CJ and MP conceived the design of the study. VS drafted this version of the manuscript with critical revision and input from MP and CJ. All authors have read and given approval for this version. VS is the guarantor of the manuscript.

Acknowledgements:

Authors would like to acknowledge support from the three members of the patient and public engagement and involvement group set up as part of the carers' experience of assistive technology use in dementia study. The authors also acknowledge support received from Mr James Grassom from the Join Dementia Research website, the OxDARE database, the CHAIN network and healthcare professionals for their support in recruiting participants.

Tables

Table 1: Participant characteristics
| Sex          | N   | %   |
|--------------|-----|-----|
| Women        | 131 | 65.2|
| Men          | 65  | 32.3|
| Other        | 1   | 0.5 |

| Living arrangements | N   | %   |
|---------------------|-----|-----|
| Living with person with dementia | 103 | 51.2|
| Living away from person with dementia | 98  | 48.8|

| Ethnicity | N   | %   |
|-----------|-----|-----|
| White     | 186 | 92.5|
| Indian/Indian British | 4   | 2   |
| Mixed/multiple ethnic groups | 3   | 1.5 |
| Other     | 1   | 0.5 |

| Marital status | N   | %   |
|----------------|-----|-----|
| Single         | 17  | 8.5 |
| Married/civil partnership | 158 | 78.6|
| Divorced/legally dissolved civil partnership | 22  | 10.9|
| Widowed/surviving partner | 3   | 1.5 |

| Highest level of education | N   | %   |
|----------------------------|-----|-----|
| Secondary school           | 8   | 4.0 |
| College (further education) | 58  | 28.9|
| Undergraduate university degree | 76  | 37.8|
| Postgraduate university degree | 51  | 25.4|
| Other                      | 8   | 4.0 |

| Annual family income | N   | %   |
|----------------------|-----|-----|
| Less than £10,000    | 7   | 3.5 |
| £10,001 - £40,000    | 86  | 42.7|
| £40,001 - £70,000    | 49  | 24.4|
| Greater than £70,000 | 11  | 5.5 |
| I do not wish to say | 47  | 23.4|

| Relationship with person with dementia | N   | %   |
|----------------------------------------|-----|-----|
| Parent                                 | 110 | 54.7|
| Sibling                                | 3   | 1.5 |
| Friend                                 | 2   | 1.0 |
| Neighbour                              | 1   | 0.5 |
| Spouse                                 | 72  | 35.8|
| Grandparent                            | 3   | 1.5 |
| Other                                  | 10  | 5.0 |

| Age (Minimum – Maximum); Mean (SD) | 33 - 92 Years; 61.67 (12.07) |

Table 2: Types of Assistive Technology
| Type of Assistive Technology in use                                      | N (% of participants) | AT no longer in use N (% of participants) |
|-------------------------------------------------------------------------|------------------------|-------------------------------------------|
| Assistive robot(s)                                                      | 1 (0.5%)               |                                           |
| Flood detector                                                          | 2 (1.0%)               |                                           |
| Robotic pet(s)                                                          | 2 (1.0%)               |                                           |
| Satnav in car                                                           | 2 (1.0%)               |                                           |
| Bath lift                                                               | 2 (1.0%)               |                                           |
| Electric toothbrush                                                     | 3 (1.5%)               |                                           |
| Stair lift                                                              | 4 (2.0%)               |                                           |
| Digital photo frame                                                     | 4 (2.0%)               |                                           |
| Hoists                                                                  | 5 (2.5%)               |                                           |
| Electronic mattress                                                    | 5 (2.5%)               |                                           |
| Automatic gas switch-off device                                         | 7 (3.0%)               | 2 (2.4%)                                  |
| Stove timer                                                             | 7 (3.0%)               |                                           |
| CCTV                                                                    | 8 (4.0%)               | 1 (1.2%)                                  |
| Baby monitors                                                           | 11 (5.5%)              | 1 (1.2%)                                  |
| Riser recliner chair                                                    | 11 (5.5%)              |                                           |
